SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered almost exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now free to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in these departments during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease.

MATER MISERICORDIÆ HOSPITAL.—This hospital, containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary, held on Tuesdays and Saturdays. Lectures on clinical gynæcology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery will be taught in the special wards and dispensary. A special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general, medical and surgical diseases, accidents, &c. Leonard Prizes: One gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and one silver medal in the subject of surgery. Junior Leonard Prizes: Two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery respectively.

MERCER'S HOSPITAL.—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. R. Charles B. Maunsell, M.B., F.R.C.S., 32 Lower Baggot Street, Dublin.

ST. VINCENT'S HOSPITAL was established in 1834, it has 160 beds, and in connection with it there is a largely-attended dispensary, a convalescent home, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are

illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Dr. Dargan, 45, Stephen's Green, East Dublin.

DR. STEEVENS' HOSPITAL, situated at Kingsbridge, is one of the oldest and largest of the clinical hospitals in Dublin, and contains over 200 beds. Recently, a very fine Nurses' Home has been added to the institution, with accommodation for over seventy nurses. And a new and thoroughly equipped dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while the special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

JERVIS STREET HOSPITAL is the oldest established in Dublin. The new hospital was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Two resident surgeons are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons.

Students of Jervis Street Hospital are entitled to attend free of charge the Children's Hospital, Temple Street, which contains 100 beds, and where special lectures are given on Diseases of Infancy and Childhood, and on Orthopædic Surgery and appliances, and to obtain special courses in fevers at Cork Street Fever Hospital.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Throat Hospital, the Orthopædic Hospital, the Children's Hospitals in Harcourt Street and in Temple Street, and the City Hospital for Diseases of the Skin.

THE ROTUNDA HOSPITAL.—This institution is the largest, the longest established, and the most famous gynæcological as well as maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. The number of patients admitted to the hospital, and also attended in the extern maternity has increased enormously within recent years. The routine daily work comprises the attendance of lectures on midwifery and gynæcology; practice in abdominal palpation; personal conduction of parturition both in the extern and the intern maternities; cystoscopic examinations, as well as attendance at the operation work of the hospital. The hospital affords exceptional advantages to qualified men who take out a three months' course during the autumn, winter, and spring months, for they (if considered competent) are permitted a certain amount of practical operation work, viz.—forceps, curettings, perineorrhaphy, &c. Students are liable to summary dismissal without refund of fees for gross misconduct, or serious breach of the hospital rules. A special afternoon class in gynæcology is held by the Senior Assistant, £2 2s. per month. The Pathological laboratory under the direction of Dr. Rowlette has become an important feature of the hospital. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynæcology is presented to students whose work meets with the Master's approval. Paid clinical assistants are selected (from among those who have obtained the hospital L.M. certificate) by competitive examination, for periods of six months. The residents' quarters have undergone complete renovation and now afford comfortable accommodation. The grounds of the hospital contain asphalt and grass courts for lawn tennis and croquet. There is also a full-size billiard table.

Fees for Pupils.—Intern:—One month, £6 6s.; two months, £9 9s.; three months, £12 12s.; six months, £21; single months other than the first, £4 4s; board and lodging in the house per week, £1 5s. Night students (not resident in house), £6 6s. for first three months; £4 4s. for the second three months. For further particulars apply to E. Hastings Tweedy, Master, Rotunda Hospital, Dublin.

COOMBE LYING-IN HOSPITAL.—This hospital consists of two divisions, one of which is devoted to lying-in cases, and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland; nearly 18,000 cases are treated annually, either as intern or extern patients. Lectures are delivered, practical instruction is given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the diseases of women and children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. This is the largest dispensary of its kind in Dublin. There is no extra charge for attendance at this dispensary. There is accommodation for a number of qualified and unqualified intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. Clinical assistants are appointed from among the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. The residents' quarters have been much enlarged. A billiard table has been erected for the use of students. Extern pupils pay, for full course of six months, £8 8s. Intern pupils pay one month, £4 4s., six months, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students' intern pay for one month, £5 5s.; each consecutive month, £4 4s.

* NATIONAL MATERNITY HOSPITAL.—This institution, under the mastership of Dr. Barry and Dr. A. Horne, is situated in Holles Street.

SIR PATRICK DUN'S MATERNITY.—This is a branch of Sir P. Dun's Hospital, and is under the management of the King's Professor of Midwifery in Dublin University. The department is at present in process of being reorganised.

CORK STREET FEVER HOSPITAL is the only special fever hospital in Dublin. It is supported mainly by subscriptions, an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer sessions to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

THE NATIONAL CHILDREN'S HOSPITAL for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded

in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

*THE CHILDREN'S HOSPITAL, DUBLIN (under the care of the Sisters of Charity).—This institution is one of the most progressive and up-to-date children's hospitals in the Kingdom, besides being the largest in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. During the last year a new operating theatre has been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopædic surgery, and the number of deformities from all parts of Ireland treated and cured in the hospital is rapidly increasing. A special masseuse has been appointed to the hospital to aid in this department.

The hospital is recognised for clinical instruction in the diseases of children by the R.U.I. and licensing bodies, which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to M. C. Staunton, hon. sec., or to any member of the staff.

THE INCORPORATED ORTHOPÆDIC HOSPITAL, IRELAND.—This hospital was founded in 1876, and contains 80 beds. It is available for every class of deformity available for treatment. Particulars may be obtained from Captain Borthistle, Registrar, at the hospital, or from R. L. Swan, F.R.C.S.I., 32 Stephen's Green.

THE ROYAL VICTORIA EYE AND EAR HOSPITAL, Adelaide Road, Dublin.—This hospital, which was opened in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Special classes for practical instruction in the use of ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

THE INCORPORATED DENTAL HOSPITAL, Lincoln Place.—This hospital, recently erected, is the only special Dental Hospital in Dublin. It is officered by a very strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £15 15s. for the first year's study, and £12 12s. for second, and proportionately smaller fees for shorter periods.

THE CITY HOSPITAL FOR DISEASES OF THE SKIN AND CANCER, Great Brunswick Street.—The first and only one of its kind in the city was the first in Ireland to instal the Finsen treatment. Senior students are admitted free to the practice of this hospital, which has a large daily out-patient attendance, with 15 beds available for the admission of acute cases. Classes of instruction will be given at regular intervals during the winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances, rectifiers and transformers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work. Fluorescent screen, and how to localise foreign bodies.

BELFAST HOSPITALS.

*HOSPITAL FOR SICK CHILDREN, Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A very large extern is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. The convalescent home, which is situated at Newtownbreda, contains thirteen cots, and its situation and equipment render it an admirable adjunct to the after-treatment of the cases admitted to the hospital. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Friday of each week at 9 a.m.

* MATER INFIRMORUM HOSPITAL.—Established 1883. 160 beds. The New Mater Hospital, which was erected at a cost of over £50,000, was formally opened on April 23rd, 1900. During the year the intern patients numbered 1,525; accidents, 3,762, and cases treated in the Dispensary, 22,597; 389 surgical operations were performed with the most satisfactory results. The total number of patients who received treatment was 27,884, being an increase of 1,517 as compared with the year 1904. A notable feature is in the number of accident cases, as the hospital is conveniently situated in proximity to a large working-class population, and within easy reach of most of the public works.

THE BELFAST MATERNITY HOSPITAL (INCORPORATED).—Established 1794. 25 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by the Royal University, &c., &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. Conditions for such on application to the Matron. During the year 1905, 326 patients were treated in the hospital, and 312 patients at their own homes. Besides this, 186 patients were dealt with in the extern gynæcological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff, on or before November 1st and May 1st.

Note.—Hospital was rebuilt in 1904 and removed to splendidly equipped new premises in Townsend Street. A Resident Surgeon elected periodically.

OPHTHALMIC INSTITUTION AND EYE AND EAR HOSPITAL, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1867. New extern department and operation theatre added, 1902. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday, Wednesday and Friday at noon for eye cases, and on Monday and Thursday at noon for ear and throat cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 18 College Square East, Belfast.

ROYAL VICTORIA HOSPITAL.—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17th, 1903. 300 beds; Convalescent hospital, 24 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

ULSTER EYE, EAR, AND THROAT HOSPITAL.—Established 1871. New hospital opened 1874. 30 beds.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN, Mountpottinger, Belfast, is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working class district, and has a great field for its charitable operations. There are in the hospital about twenty-two beds for children and eight for women. There is an

extern department for children open every week-day, except Saturday, from 9 till 10, and for women at 11.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Saturday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

CORK HOSPITALS.

VICTORIA HOSPITAL FOR WOMEN AND CHILDREN.—Established 1874. 70 beds. An immense amount of work is done in this hospital to relieve the poor of Cork, Kerry, and other counties. This year a fine new anæsthetic room has been added to the already perfect theatre, where a large number of successful operations are done every year. The hospital contains several very fine private rooms for paying patients.

* COUNTY AND CITY OF CORK LYING-IN HOSPITAL.—Established 1798. 17 beds.

* EYE, EAR, AND THROAT HOSPITAL, Western Road.—Incorporated 1898. 35 beds. Inpatients treated during year, 454; outpatients, 4,238. Clinical Instruction is given during college session. Special demonstrations in the use of the ophthalmoscope, larynogscope, &c., are given from time to time.

* FEVER HOSPITAL AND HOUSE OF RECOVERY.—Established 1801. 110 beds.

* MATERNITY.—Established 1872.

* MERCY HOSPITAL.—Established 1857. 80 beds.

* NORTH CHARITABLE INFIRMARY.—Established 1774. 110 beds. Spec al wards for treatment of diseases of women and children. The extern department is largely availed of, and the number of accidents treated is very large. Clinical instruction is given daily from 9.30 a.m. to 12 noon. A new and thoroughly up-to-date operating theatre has recently been added at enormous expense.

CORK SOUTH INFIRMARY AND COUNTY HOSPITAL.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are also special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extern department.

Clinical instruction is given daily during the session from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly delivered.

The operation and sterilising rooms are thoroughly up to date. The X-ray department is fully equipped with the newest apparatus necessary for such work. Students are regularly instructed in the methods of using the rays by practical demonstration on the cases requiring their use.

The hospital has been largely availed of by students of the Cork School of Medicine.

GALWAY HOSPITALS.

* COUNTY HOSPITAL.—Established 1786. 60 beds.

* No answer to our request for information received from these hospitals.

IRISH PUBLIC SERVICES.

THE POOR-LAW MEDICAL SERVICE.

For several years past the unsatisfactory nature of the Irish Poor-law Medical Service, as a career for young practitioners, has furnished a theme for the opening addresses at all the leading medical schools. In addition to the petty annoyances, the laborious and harassing duties, and the ever-increasing amount of clerical work which the new orders of the Local Government Board impose from time to time, the unfortunate medical officers are grievously underpaid, their salaries being totally out of proportion to the duties discharged, and in the majority of rural districts barely sufficent to cover the out-of-pocket expenses, such as are incurred in the keep of a horse and man, and other servants. The Local Government Board have recently laid it down, moreover, that the dispensary patients have the first call on the time of the medical officer, and that, even if he is engaged on an urgent private case, he must give it up and go off to attend on a scarlet-runner, as the dispensary visiting tickets are not inappropriately called. So strictly is he bound up to the discharge of his duties that unless incapacitated by sickness or other cause, or with the permission of the guardians expressly granted, he cannot leave his district for a single day, even if he makes provision for the performance of his duties in his absence by a brother practitioner. The Irish Medical Association, whose work it is to safeguard the interests and improve the condition of the Poor-law medical officer, considers it an imperative duty to point out to young practitioners the following facts: (1) That the Poor-law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements, and more costly and difficult to procure, almost the same rate of payment given to less educated men forty years ago is still offered, and this, too, at a time when the rural prosperity of the country is less, and consequently lucrative private practice more difficult to obtain. (4) That there is no compulsory superannuation, and, as a consequence, many old and infirm doctors are forced to remain on in the Service long after they have become unfit to discharge the duties, seeing nothing but extreme poverty and perhaps the workhouse itself staring them in the face.

We need go no further than to say that the Irish Poor-law Medical Ser vice is a service to avoid. We therefore strongly urge on young medical men the importance of supporting the interest of the profession by refraining from applying for vacant posts of which the salary is nsufficient, from accepting posts as *locum tenens* at a lower rate than £4 4s. per week.

There are 159 workhouses and about 810 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service used to average about £114, but is rapidly coming down, and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

Qualifications.—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the "Medical Register," if effected since the passing of the Medical Act, in 1886, fulfils all requirements. The candidate must also be 23 years of age.

Duties.—The duty of the dispensary doctor is twofold. He has to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a guardian, warden, or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in many districts he has to make up all the medicines for the poor.

Workhouse Hospitals.—The number of unions in Ireland is 159, to each of which is attached a medical officer, who is appointed and controlled by the board of guardians in the same manner as the dispensary medical

officer. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

THE IRISH LUNACY SERVICE.

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salaries and emoluments averaging about £200 a year. There are also Visiting Physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The Superintendents and Assistants must devote their whole time to their duties.

Heretofore the appointments of Medical Superintendents have been in the patronage of the Lord Lieutenant, but, under the Local Government Act, they are in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistant is appointed by the Committee of the County Council to which the management of the the asylum is entrusted. In addition to these officers, there are, in certain larger asylums, Clinical Residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

OTHER APPOINTMENTS.

There are, in addition to those which we have mentioned, certain appointments open to medical practitioners in special localities. They are :—

(1) Attendance on the Royal Irish Constabulary. (2) Attendance on the Coastguards. (3) Factory Surgeoncies. (4) Attendance upon the depôt soldiers who are not otherwise provided for.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men, but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local District Inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

The Coastguard Service.—The duty of the Medical Officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor-law Medical Officer. The emoluments depend on the number of stations and men.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depôts is not worth mentioning.

Scotland.

NOTWITHSTANDING the increased competition which the recent vigorous growth of the great English provincial medical schools, added to the unsurpassed attractions of the historic Metropolitan hospitals, with their staffs of renowned teachers, ensures, the Scottish medical schools seem fully to retain their popularity, not only, as is natural, among Scotsmen and their colonial descendants, but among medical students from England, Wales, and Ireland, and, indeed, all parts of our Empire. In fact, if appearances be any guide, it would seem that the number of Oriental students attending classes in Edinburgh is increasing year by year. And undoubtedly the competition of other centres has had the advantage of making Scottish teachers bestir themselves, with the result that the efficiency of the medical schools is now much greater than a decade ago. The advantages derived from the second half of the Carnegie Bequest, *i.e.*, the improved equipment of the teaching schools and the encouragement of post graduate research are now manifesting themselves, and will prove permanent factors in promoting the well-being of the Universities and Scottish education generally. Of the four universities, Edinburgh, of course, occupies the premier position as a medical school, but at Glasgow, Aberdeen, and St. Andrews, an almost equally good—indeed, in individual details, better—training can be obtained. Two ordinary qualifications to practise are granted in Scotland—the M.B., Ch.B. of the Universities, and the triple qualification of the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. The examinations for the University degree naturally are more exacting than those for the triple qualification, and the curriculum wider. Nevertheless, the standard for the latter is being steadily raised, though on account of the large number of examiners in most subjects it is probably slightly less uniform than that of the universities, where the examinations are conducted by the professors with one or more extra-mural assessors in each subject. Two features of the Scottish system deserve mention—first, as regards the co-ordination of various separate teaching bodies in each centre ; second, as regards the conditions under which the students live, Around each university there has grown up an extra-mural medical school, in which the teachers are hospital physicians, surgeons, and specialists unconnected with the university, but whose classes qualify for graduation. Thus the student has usually ample choice, and can, within certain limits, attend the teacher from whom he thinks he will derive most benefit, while the extra-mural lecturers, being unendowed and constantly recruited by fresh blood, have a permanent incentive to keep their courses up to the mark, since any slackness is at once followed by a diminution in the number of students' fees. In hospital work it is the same, the student having the option of attending a clinical professor and an ordinary physician or surgeon. A very important part of the student's clinical work, too, is done at institutions and under teachers quite unconnected with the universities ; this is his dispensary practice, which may be taken at one of several dispensaries situated in the poorer districts of the towns. Until recently, practical training in obstetrics was one of the least satisfactory parts of the teaching in Edinburgh, and many students were in the habit of going to Glasgow or Dublin for their maternity work. Recently, however, steps have been taken which should render this unnecessary, and ought to give Edinburgh students quite sufficient opportunity of acquiring as good a practical acquaintance with this most important subject as they have of obtaining a theoretical knowledge of it. From what has been said it will be seen that university undergraduates and triple qualification men rub shoulders at every turn—in the wards, dispensary, and lecture-room. University students have the privilege of studying

under both intra- and extra-mural teachers, while men going up for the triple qualification are limited to the latter. It is not uncommon, therefore, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or *vice versâ*, and this can usually be done without much added expense or taking out many fresh classes, provided the change is not made too late in the curriculum. The weak spot in the Edinburgh curriculum is the overcrowding of subjects in certain years. The most feasible means of remedying this would seem to be a division of the *annus medicus* into three instead of two sessions, a scheme which has received a certain amount of support, but is as yet far from becoming *un fait accompli*.

For the rest, the student lives as he likes and where he likes; the authorities only demand that he shall attend classes with due regularity and diligence, and exhibit sufficient proficiency to pass his examinations. Most men live in lodgings, a few board with private families, and some live in the various halls of residence which have been established. In these last, too, the student is his own master, the halls being managed solely by a committee of the residents for the time being. It is impossible to make any very definite statement as to the relative cost of a medical education in the different schools, as compared with London and Dublin, as so much depends on the extra classes taken out, the mode of living, and so on. The minimum inclusive fees for the licence are £120, for the M.B. degree about £145; but almost every student finds it practically necessary to attend additional classes. On the whole, the cost of living is highest in Edinburgh, lowest in Aberdeen; in the former, while the rent of lodgings is lower than in London, maintenance, including clothing and provisions, is somewhat more expensive. Incidental expenses, amusements, &c., are, however, considerably less in the Northern capital. In Aberdeen, money goes much further than in the south, and the student ought to keep himself on about two-thirds of the funds required in Edinburgh.

THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made "of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards, or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Hanover Street, Edinburgh.

Scholarships, Fellowships, and Grants in aid of original research are now awarded annually by the Trust. For particulars, conditions, &c., apply to the Secretary.

UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted: Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical and surgical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in Arts or Science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English grammar and composition, English history and geography, Latin, aritbmetic, and the elements of mathematics, and Greek, or French, or German.

The *annus medicus* of each year is held to be constituted by at least two courses of not less than one hundred lectures each, or by one of such courses, and two courses of not less than fifty lectures each, exclusive of the clinical courses, in which lectures are given twice a week during prescribed periods. Two years of the five must be spent at the University, the remaining three years at any University of the United Kingdom, or other Universities or Medical Schools recognised by the University Court.

During the first four years the student must attend botany, zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than forty lectures; practical anatomy, during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery, materia medica, medicine and midwifery during courses of not less than five months each. Eight of these subjects must be taken at a University or college affiliated to a University entitled to grant the degree of M.D. He must attend a course of twenty-five lectures on practical pharmacy in a University or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation he must have attended for at least three years a hospital which accommodates no fewer than 80 patients, and possesses a distinct staff of physicians and surgeons, and he must have acted as clerk in the medical and dresser in the surgical wards of such a hospital, and attended for six months the practice of a dispensary, or of a physician and surgeon. He must also have had approved opportunities of studying (1) operative surgery; (2) mental diseases at a recognised asylum; (3) at a recognised hospital, *post-mortems*, fevers, and diseases of the eye; and (4) one of the following: Diseases of children, of the ear, nose and throat, or of the skin; (5) vaccination.

He must personally attend at least twelve cases of labour under the superintendence of a registered medical practitioner, or six such cases, and, for at least three months, the practice of a midwifery hospital in which practical instruction is regularly given.

Every candidate must deliver on or before the date for lodging certificates for the final examination to the Dean of the Faculty of Medicine:—

1. A declaration in his own handwriting that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master. (This declaration, along with a statement of studies, is appended to the schedule for the Final examination, and must be signed before the schedule is given in.)

2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied by proper certificates.

Each candidate is examined both in writing and *viva voce*:—

1. On zoology, botany, physics, and chemistry.
2. On anatomy, physiology, and materia medica and therapeutics.
3. On pathology.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

The examinations in anatomy, chemistry, physiology, botany, and zoology, materia medica and pathology are conducted, as far as possible, by demonstration of objects placed before the candidates.

Candidates who are ready to submit to an examination in the subjects comprised in the first division, *viz.*, botany, zoology, physics, and chemistry, may be admitted to examination in all or any two of these subjects at any examination held after they have attended a full course in each of the subjects professed.

Candidates who have passed their examination in the subjects in the first division may go up for examination

in those of the second division at the end of their third winter session, but may postpone their examination in materia medica and therapeutics until the close of the summer session following.

Candidates who have passed the first and second divisions may be examined in the third division at the end of the fourth winter session.

Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division, when they have completed the fifth year of study.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and Ch.B., for at least one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical services, or for two years in practice other than purely surgical. The candidate shall submit to the Faculty of Medicine a thesis certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery, which he may have made a subject of study after having received those degrees. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he *may* take, at option, gynæcology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B., C.M. (Old Regulations), on the submission of a thesis approved by the Medical Faculty, provided that the candidate shall have passed the medical preliminary examination in the subjects of Greek and logic or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D. degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar, the candidate being examined in surgical anatomy, operations on the dead body, clinical surgery, and some of the special branches.

Candidates settled abroad, who cannot appear personally to receive the degree, may, after satisfying the Senatus to that effect, have the degree conferred on them *in absentia*.

Fees:—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas, and the proportion of this sum to be paid by a candidate at each division of the examination is regis tered from time to time in the University Court. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (Old Regulations, £5 5s.).

The total expense of the curriculum, including examination and matriculation fee, is £146.

Among scholarships, &c., open for competition during the Session 1906-7, are the following:—Syme surgical fellowship, £112; Goodyer Memorial fellowship in anatomy, £100 for two years; Allan Fellowship, £52, clinical, medicine and surgery; Eccles scholarship, £32; Sibbald medical scholarship, £40; Thomson scholarship, botany, zoology and Physics; £40; Vans Dunlop scholarship in preliminary subjects, £100; Crighton research scholarship in materia medica and pathology, £100. For the conditions attaching to these and a great many other fellowships, scholarships, bursaries and prizes the University Calendar should be referred to.

Graduation in Public Health: Degrees (B.Sc. & D.Sc.) are also conferred in Public Health. Candidates must be graduates in medicine of a University recognised by the University Court, and must matriculate for the year in which they proceed for examination. Before proceeding to the first examination they must produce evidence that (1) they have worked at least twenty hours a week during a period of not less than eight months, after taking their medical degree, in a recognised Public Health laboratory—five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh; and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one, of at least three months' duration, on geology, such as the Senatus may approve of.

Candidates for the second examination of B.Sc. in Public Health are not admitted until at least eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two separate courses of Public Health, of at least forty lectures each, one dealing with medicine, the other with engineering, each in its relation to public health, in such manner as the Senatus shall determine. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' clinical instruction in a recognised fever hospital, and three months' instruction in mensuration and drawing.

Full details of the subjects included in the different courses are given in the official programme of the Faculty of Science, which may be obtained from the University (price 2d.).

In a similar manner to that described under degrees in pure science, a B.Sc. may after five years proceed to take the degree of D.Sc. in Public Health.

Fees for Science Degrees: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.; D.Sc., £10 10s.; total, £16 16s.

Diploma of Tropical Medicine.—Every year an increasing number of candidates avail themselves of the University Diploma of Tropical Medicine and Hygiene, which is conferred only on those possessing a degree in medicine. The course of instruction includes practical bacteriology, diseases of tropical climates, tropical hygiene, three months each; practical instruction on the zoological character and life history of disease-carrying insects and venomous animals—one month; clinical instruction at an hospital for tropical diseases—six months. The examination is held in January and July, the fee being £4 4s.

University Hall, Edinburgh.—In an educational number it is worth while to call attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that many graduates live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents, or other suitable person. These are considered and voted on at a house meeting. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

Medical School for Women.—The medical teaching of women in Edinburgh is carried on by the Scottish Association for the Medical Education of Women (the Secretary, Minto House, Chambers Street). The classes are conducted by the lecturers of the Medical School of the Royal Colleges, and qualify both for the Edinburgh University degree and for the Licence of the Triple Board. The classes are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary mathematics, and (4) Greek, French, or German, with possible option to students whose native tongue is not English in the case of the fourth subject, and, on passing, students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the assistant clerk, Matriculation Office.

The fees for M.B. and Ch.B. are £23 2s.; for M.D. £10 10s., and for Ch.M. £10 10s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £3 3s., for each winter session, and £2 2s. for each summer session of clinical instruction. There are three very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospitals, the Maternity Hospital, the Sick Children's Hospital, the Eye Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health are also now conferred. Of late the University has made considerable efforts to extend its laboratory accommodation and equipment, to augment its teaching staff, and to encourage post-graduate and research work. Within the last few years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,900); while new laboratories, to cost, with equipment, upwards of £60,000, are now approaching completion, for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £1,000 are appropriated to medical students, including an Arthur bursary for women, £20 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

Queen Margaret College for Women. — Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded in 1894. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees; and several bursaries are open to women students of medicine.

The Winter Session begins on 18th October. The prospectus can be obtained from the hon. sec., Miss Galloway, Queen Margaret's College, Glasgow.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery, besides a Lectureship in Tropical Medicine. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Edinburgh; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Total cost, exclusive of the fees for degrees, is about £120. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

BURSARIES.—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,180, may be held by students of medicine. (See "University Calendar.")

THE DEGREE OF M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and C.M. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in military or naval medical service, or in medical or surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary the Medical Faculty.

Aberdeen Royal Infirmary.—This is a well-equipped institution, containing 250 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREWS UNIVERSITY,

UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE.

This University (session opens October 15th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for

the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination :—Chemistry, physics, bacteriology, and meteorology. Second examination :—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

University College, Dundee, was affiliated and made to form part of the University of St. Andrews on January 15th, 1897, and the whole medical curriculum may be taken in the College. The United College, St. Andrews, offers classes for the first two years of professional study.

BURSARIES AND SCHOLARSHIPS.

United College, St. Andrews.—Malcolm bursary, £25 a year, tenable for five years). Fourteen Taylour Thomson bursaries, £30 to £20, five tenable for one year, nine for two, open to women only proceeding to graduate in medicine.

University College, Dundee.—Eleven entrance bursaries of £15, open to women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in arts, science, or medicine, tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year. Two Educational Trust bursaries of £25, tenable for three years. Applicants must have attended a public or State-aided school in Dundee for at least one year before examination. Bute bursary, annual income from £1,000 (men only).

Preliminary Examinations.—The dates of the next two examinations are September 28th, 1906, and March 24th, 1907. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by September 15th, 1906, or March 13th, 1907.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, *i.e.*, 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations.

Class Fees.—The fee payable in each of the following classes is 4 guineas, *viz.*:—Chemistry, physics, zoology, botany, physiology, anatomy, materia medica pathology, forensic medicine, and public health, medicine, surgery, and midwifery. The fee for the practical classes in these subjects is 3 guineas each. In clinical surgery, clinical medicine, ophthalmology, diseases of the throat, nose, and ear, and mental diseases, the class fees are 2 guineas each. The fee for Public Health chemistry required for the D.P.H., is £7 7s. A special class in Bacteriology is also held for the D.P.H. for which the fee is 3 guineas.

Dundee District Asylum.—The appointments include a qualified resident assistant and two resident clinical clerks. Clinical instruction is given.

Further information will be found in the Calendar of the University, published by Messrs. Blackwood and Sons, Edinburgh, or can be had of the Dean of the Medical Faculty, Professor Waymouth Reid, F.R.S.

Dundee Royal Infirmary.—The Infirmary contains 300 beds, with a special ward for the treatment of children. Three resident qualified assistants are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. Out-patients are seen daily at 9 a.m. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Ticket for the Infirmary, £2 2s. each session, or £3 3s. a year. Further information on application to the Medical Superintendent.

THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after a series of examinations, the student may obtain the diploma of the co-operating bodies.

The holders thereof are enabled to register three diplomas under the Medical Acts, *viz.*, Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow. The diplomas are also recognised by the Army, Navy, and other public bodies.

The three co-operating bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery, as the case may be.

REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The candidate must produce certificates of having attended the following separate and distinct course of lectures, the certificate distinguishing the sessions and the schools in which the courses were severally attended. Anatomy, one course, six months. Practical anatomy, twelve months. Chemistry, one course, six months. Practical or analytical chemistry, one course, three months. Materia medica, one course, three months. Physiology, one course, six months. Practice of medicine, one course, six months. Clinical medicine, nine months. Principles and practice of surgery, one course, six months. Clinical surgery, nine months. Midwifery and diseases of women and children, one course, three months. Medical jurisprudence, one course, three months. Pathological anatomy, one course, three months. The candidates must also produce the following certificates :—(*a*) Of having attended not less than six cases of labour under the superintendence of the practitioner who signs the certificates, who must be a registered medical practitioner. (*b*) Of having attended for three months' instruction in practical pharmacy. The certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicine to his patients, or a teacher to a class of practical pharmacy. (*c*) Of having attended for twenty-four months the medical and surgical practice of a public general hospital, containing on an average at least eighty patients, and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended, for six months, the practice of a public dispensary specially recognised by any of the co-operating bodies; of having been engaged for six months as visit-assistant to a registered medical practitioner. (*e*) Of having been instructed in vaccination.

First Examination, Fee £5.—The first examination shall embrace chemistry, comprising the following particulars :—Chemical physics, heat, light, and electricity; the principal non-metallic and metallic elements, and their more common combinations, also the leading alcohols, organic acids, ethers, carbohydrates, and alkaloids; the candidates will also be examined practically in testing; physics and elementary biology. The first examination shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must apply to the Inspector of Certificates on or before the Friday preceding the day of examination, and must produce certificates of attendance on one course of chemistry, one course of practical

chemistry, one course of anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The Second examination shall embrace anatomy and physiology, and shall not take place before the termination of the summer session of the second year of study. Candidates must produce to the Inspector certificates of attendance on the prescribed courses of anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The Final examination shall embrace the principles and practice of medicine (including therapeutics and medical anatomy, clinical medicine); the principles and practice of surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynæcology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English language, including grammar and composition; (2) Latin, including grammar, translation from specific authors, and translation of easy passage not taken from such authors; (3) elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions; (*b*) algebra, including simple equations; (*c*) geometry, including the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following optional subjects:—(*a*) Greek; (*b*) French; (*c*) German; (*d*) Italian; (*e*) any other modern language; (*f*) logic; (*g*) botany; (*h*) zoology; (*i*) elementary chemistry.

Qualification in Public Health: The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48, George Square, Edinburgh; and for those of the Royal College of Physicians, to Dr. H. Rainy, 16, Great Stuart Street, Edinburgh.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years previously, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish University, provided he shall have attained the age of twenty-four years and shall have passed an examination (1) On the principles and practice of medicine, including therapeutics; (2) on one of the following subjects to be selected by the candidate, *in which a high standard of proficiency is expected*:—(*a*) one or more departments of medicine specially professed; (*b*) psychological medicine; (*c*) pathology; (*d*) medical jurisprudence; (*e*) public health; (*f*) midwifery; (*g*) gynæcology. The examination is of a searching character extending over three days, the first of which is devoted to the examination of patients *viva voce*, and practical examination on methods of diagnosis —*e.g.*, microscopy of blood, clinical bacteriology, quantitative analysis, &c., and written commentary on a case examined. The second day is taken up by written papers, and the third by practical examination on special subject and orals.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, in medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (*a*) Surgery, special branches; (*b*) advanced anatomy and physiology; (*c*) surgical pathology and morbid anatomy; (*d*) midwifery and gynæcological medicine and surgery; (*e*) medical jurisprudence and hygiene; (*f*) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship.

LICENCE.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 800 beds under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, diseases of the skin, eye, ear, throat and teeth, and anæsthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follow:—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.

2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments may be renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is about sixty, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the different Universities. The number of students attending the school averages 1,300 annually.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £120, which is payable by yearly instalments during the period of study.

The Winter Session opens October 2nd.

GLASGOW EXTRA-MURAL SCHOOL.

St. Mungo's College and Glasgow Royal Infirmary.—This college was incorporated in 1889 under its new title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital, and the laboratories, museums, and lecture rooms are of the most approved description. The college has been recently equipped with a complete electric light installation, and a powerful electric educational lantern. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has over 600 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for venereal diseases, erysipelas, burns, and diseases of the throat. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases—about 78,000 per annum—which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Appointments.—All appointments are open. There are five physicians' and eight surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

Fees.—The fees for Lectures, including hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to about £70.

Anderson's College Medical School, Glasgow.—New and excellently equipped buildings were opened in October, 1887, in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery. There are also provided a library and reading room, and students' recreation room. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 9 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. These students are assisted in their dissections by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissecting specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room, furnished with complete sets of painted and unpainted bones.

The various courses of instruction qualify for all the Licensing Boards in the United Kingdom, and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow, under certain conditions. The courses in public health (laboratory and lectures) are also recognised by the University of Cambridge.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from W. S. McCormick, Esq., LL.D., Carnegie Trust Offices, Edinburgh.

Class Fees.—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, and mental diseases excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s.: afterwards free. For the following practical classes, *viz.*: Chemistry, botany, zoology, physiology, pharmacy, first session, £2 2s.; second session, £2 2s.; in botany and zoology, practical and systematic course together, £3 3s. Operative surgery, £2 12s. 6d. Public health laboratory, £11 11s.; with lecture, £12 12s. Opthalmic, medicine and surgery, aural surgery, diseases of throat and nose, mental diseases—eerch, £1 1s.

Anatomy Class Fees.—Winter: First session (including practical anatomy), £4 4s.; second session (including practical anatomy), £4 4s.; third session, £2 2s. To those who have had the necessary courses of practical anatomy, the fee will be £1 1s. Summer: Lectures and practical anatomy, £2 12s. 6d; separately, £1 11s. 6d. each.

Western Infirmary.—Fees: Hospital attendance. £10 10s. (permanent); clinical instruction, winter £3 3s., summer £2 2s., pathology, £4 4s. (systematic), practical pathology, £3 3s.; vaccination, £1 1s.

Royal Infirmary.—Fees: Hospital practice and clinical instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; pathology, both courses, £4 4s.; vaccination fee £1 1s.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 15, Dalhousie Street, Glasgow. Particulars may be had from D. M. Alexander, Esq., 97, West Regent Street.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 9th, 1906.

A NEW TREATMENT OF WHOOPING-COUGH.

HAVING administered chloroform to a child to reduce a luxation of the hip, who was at the same time suffering from whooping-cough, Dr. Henri de Rothschild observed that the fits of coughing had completely ceased after the anæsthetic. The patient was held under observation for a fortnight, but no return of the whooping took place, vomiting had also ceased as well as the cyanosis of the face and the insomnia.

This case led him to suppose that the inhalation of chloroform had a direct influence on whooping-cough, and since, that is to say, five months ago, Dr. Rothschild treated nine cases of well-pronounced whooping-cough. These children, of from two to seven years of age, were chloroformed with the consent of the parents, and all were cured, two immediately, four at the end of twenty-four hours, and three at the end of a fortnight. The duration of the anæsthetic was five minutes. The object in view was not complete anæsthesia with abolition of the reflex of the cornea, but muscular resolution. In no case was it necessary to use the chloroform a second time.

CHRONIC CATARRHAL LARYNGITIS.

Treat the cause, rest the voice (professors, orators singers), suppress tobacco, alcohol, etc., which are local irritants. The nasal fossæ and the pharynx should receive, says Prof. Lacroix, particular attention.

Prescribe balsamics (tolu tar, eucalyptus, benzoate of soda, terpine).

Besides thermal treatment, which is more local than general, sulphurous preparations may be given :—

Monosulphide of sodium ..	6 grains.
Syrup of tar	6 ounces.

A tablespoonful every morning in milk.

Nux vomica is very useful for the vocal cords, and in lymphatic subjects might be added arseniate of soda, iodide of potassium, or cod-liver oil.

The local treatment, the most important of all, consists in inhalations, pulverisations, nitro-laryngeal injections and applications of caustics or astringents.

Inhalations can be made without any apparatus :—

Phenic acid	½ drachm.
Cherry laurel water	2 ounces.
Water	2 ounces.

A teaspoonful in a half a glass of eucalyptus infusion. When boiling pour into a recipient and cover it with a funnel, with the small end up, through which the patient, will inhale the steam ten minutes morning and evening.

If a pulverisator is used, the following solution will be put into the boiler :—

Phenic acid	20 minims.
Cherry laurel water	1 ounce.
Water	20 ounces.

The best preparations for painting on the vocal organ are chloride of zinc and nitrate of silver. A weak solution should be used first (1–100) and the strength may be increased gradually to 1–50 or 1–30, which latter should not be exceeded.

GERMANY.

Berlin, Sept. 9th, 1906.

BOTTINI'S OPERATION *v.* PROSTATECTOMY.

THIS subject formed that of a paper by Dr. A. Frendenberg in *Heilkund*. The author had performed Bottini's operation in 152 cases of prostatic enlargement, some of the enlargements being due to cancer. the youngest patient was 41½, and the oldest 82. The operation was performed after long—often many years—prostatic troubles. It was never performed for acute retention of urine. There were 84 cures, 45 considerable improvements; good results therefore were obtained in 129 cases, or 84·9 per cent.; 12 failures were recorded, in addition to 11 deaths. The last 52 cases showed better results, viz., 90 per cent. of good results, 5·8 of failures, and 3·8 of deaths. Amongst the cures were cases in which complete retention had been present for 5 and 10, and once even 28 years.

In order to obtain good results with Bottini's operation it should first have been practised freely on the dead body. The operator must be skilled in intravesical surgery, especially cystocopy, and he should at least know how to perform a simple litholapaxy. Whoever does not fulfil these conditions had better stick to prostatectomy.

There will be cases in which the question will crop up, which is the better? Bottini's operation or prostatectomy? The author here lays down the following dicta:—First of all, the surgeon who has not great special experience in bladder surgery will do better to do a prostatectomy than Bottini's operation.

2. Bottini's operation is on the whole a much less serious one than prostatectomy, and should therefore in weakly and aged people be preferred.

3. In younger prostatics also it is to be preferred, having regard to potency.

4. Potentia coeundi is not endangered by Bottini's operation; on the contrary, power is often increased thereby, whilst prostatectomy when limited to the projecting tumour in the bladder often endangers it and the more so the more complete the prostatectomy. In case of the latter operation the patient should be instructed beforehand as to the probable impotence following it.

5. Bottini's operation is advisable in comparatively small and medium-sized prostatic enlargements. The magnitude of the operation and the probability of relapse increase with the size of the growth, whilst in prostatectomy mere size does not add materially to the difficulties.

6. If a *barriere* of the prostate causes the hindrance to the outflow, complete success will almost always be obtained by Bottini.

7. Spherical and pedunculated middle lobes are more suitable for prostatectomy.

8. If it is impossible to find out the condition before operation, and especially by means of the cystoscope, prostatectomy—the high operation—is generally to be preferred.

9. Calculi, so far as they can be removed by litholapaxy (with subsequent cystoscopic control), are no direct contra-indication of the Bottini operation, but they turn the scale in favour of prostatectomy.

10. Cystitis, with acid urine and pyelitis of moderate degree, are neither against the Bottini operation nor prostatectomy. But before operation the urinary condition must always be improved as much as possible. In ammoniacal cystitis the Bottini should not be performed until the ammoniacal reaction has been put right (this may be readily done by injection of iodoform or vioform or isoform), as otherwise the scabs will become encrusted with phosphates. During the after treatment also the urine must always be kept acid.

11. Bottini should not be done whilst fever is present. Prostatectomy, on the other hand, may bring about reduction of the fever by rest and drainage.

The author does not agree with what Roosing has said about so-called atony of the bladder being a contra-indication of Bottini's operation. There may be cases in which the muscular coats of the bladder have become so changed, that even when all hindrance with flow of urine is removed, the bladder does not regain the power of expulsion; but this is only very exceptional, and even then abdominal pressure will do a great deal. As a rule, the muscular coats of the bladder regain their expelling power, and this in a surprisingly short time, when once the hindrance to the outflow is removed.

The best interests of the patient are furthered when the question comes up whether a radical operation shall be recommended, by most carefully reckoning up the general condition, the kind and degree of obstruction with outflow of urine, but any supposed weakness of the muscular coats of the bladder may be almost or altogether disregarded.

HUNGARY.

Budapest, Sept. 9th, 1906.

At the recent meeting of the Budapest Inter-hospital Association Dr. Schmidt discussed the

Value of Tuberculin Reaction.

He proved that the tuberculin reaction is not infallible in tthe diagnosis of tuberculosis. His technique is as follows :—After absence of fever has been assured for several days by four hourly measurements, one m. of tuberculin in fiesh solution is injected, then after four to five days, five times this amount. In sixteen cases with positive reaction, tuberculosis was found at autopsy in only nine; in two carcinoma of the liver and stomach were the sole lesions, in five other pathological conditions. In one there was no reaction, yet evident tuberculosis. Despite such small doses and great care in injecting, serious accidents may occur, and a latent process may suddenly become active and even lead to a rapid fatal issue. This happened to the author in three cases—one of leprosy (in Bosnia) combined with tuberculosis, and one of affection of the serous membranes. A source of error is to be found in hysterical patients ; they sometimes re-act after tuberculin injections and even after injections of plain water.

Dr. Deak related his experiences with the treatment of ozæna. He said, that it has been suggested by several observers that some etiological relation existed between this disease and abnormal width of the nares, and the proposition was therefore made to influence the course of the process by diminishing the size of the opening. This may be accomplished by the injection of paraffin into the inferior turbinale bone, and Dr. Deak has employed the method in five cases. The nose is carefully cleaned and all crusts removed. The site of operation is then thoroughly cocainised, and the paraffin injected into the most atrophied part of the turbinate, and if necessary into the septum. Both sides may thus be healed at one or more sittings. All the cases showed distinct improvement, the relief from symptoms being very marked, although in no instance did a complete cure result. The only unpleasant sequelæ were pains in the frontal region in few cases, which disappeared, however, in the course of a day. Hard paraffin, with a melting point of 50 to 52 C. is recommended as being most suitable and safest.

Dr. Morelli discussed the question of the action of Rontgen Rays. Most observers believe that the skin is affected primarily and most strongly by the X rays if a portion of the body is exposed to their, influence, but Morelli made the startling statement that the blood vessels re-act before the skin. All lesions of the skin and connective tissue are thus an expression of nutritive disturbance secondary to vascular alteration. The following experiments support this view :—If a diseased area of skin is excised the raw surface may be covered with skin-graft which will rapidly heal in place. If the skin is first exposed to the Röntgen Rays before it is transplanted the healing will be just as rapid, while an equal amount of exposure where the skin is not removed will lead to superficial ulceration. One may even preserve the exposed grafts for two days in normal salt solution and then transplant them successfully on some other individual, showing that there is not the slightest loss of vitality. If a granulating surface is exposed and then covered with normal grafts, these will be cast off a few days later. The cornea of a rabbit will not be influenced by an exposure which causes falling out of the hair in other parts of the body, simply because the cornea contains no blood vessels. The blood itself does not seem to be affected by the X-rays, for even prolonged exposure both in vivo and in vitro, did not change the microscopical appearance or the hemolytic power. The most important systemic reaction after exposure is a slight increase in temperature, and an increased metabolism, manifesting itself in an abundance of nitrogenous material in the urine.

LETTERS TO THE EDITOR.

TRUTH AND THE MEDICAL PROFESSION.

To the Editor of the Medical Press and Circular.

Sir,—No doubt it is of immense importance that *Truth* should have taken up alone among lay papers the championship of the medical profession. The value of this championship may be perhaps inferred from the character of the numerous medical advertisements which appear in its pages. Perhaps you will allow me to enumerate a few of these which have been published in the last two numbers. The issue of August 29th contains an advertisement of "Dr. Alabone's Treatment for Consumption, which has succeeded in restoring to perfect health many who had been given up as '*incurable*' by eminent consultants." On another page of the same number a column advertisement describes the virtues of "Sanatogen," which, "through regenerating the nervous system restores the functions of the digestive organs, and by rebuilding the whole body compensates the wear and tear of latter day life." The issue of September 5th contains an advertisement of "Reveille Pills," "a positive cure" for ten named diseases, including "anæmia, dyspepsia, and all nervous affections." The same number contains advertisements of "Hair Capsuloids," "Harrod's Cure for Asthma," "Beecham's Pills," "Mrs. Adair's Certain Cure for Double Chins," "Phosferine, the greatest of all Tonics," "Clarke's Blood Mixture," which permanently cures a number of diseases, including "scrofula, blood poison, rheumatism, gout and skin diseases," and the Turvey treatment of alcoholic excess and the drug habit, which are "cured at home in three to seven weeks." Not the least interesting among these announcements is Mr. Labouchere's personal testimonial in praise of "Goodman's, Ltd.," "originators of the popular guinea sets of artificial teeth."—I am, Sir, yours truly,

An Obscure Practitioner.

ARMY (REFORM) BREAKDOWN AND ENTERIC FEVER.

To the Editor of The Medical Press and Circular.

Sir,—Notwithstanding the statement that 'enteric is in all cases a water-borne disease," I cannot help thinking that numbers of cases of death among our troops in South Africa (entered under the heading enteric) were far more likely to be genuine cases of ptomaine poisoning, and I am the more confirmed in this conviction by the reply given to a member, who at my suggestion, asked the question in the House : How much of the meat supplied to our troops had come from Chicago in tins ? The reply being, "*more than half.*" This reply should give grounds for thought; and if it is the fact (which I have heard more than once) "that a post-mortem examination is made on the body of every soldier dying from disease while on active service" it should make it all the more unlikely that so many should be listed under the convenient heading of enteric fever during the South African war.—Yours, &c.,

[Alexander Duke.

London, W.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

NOTICE TO HOSPITAL AND COLLEGE DEANS.

THE Editor desires to thank those gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various medical colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

GRATUITOUS COPIES.

A VERY large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels, in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our publisher will be happy to supply him with a duplicate free of cost on receipt of address.

COACHING FOR THE EXAMINATIONS.

STUDENTS desirous of coaching facilities in preparation for the various College Examinations, and practitioners anxious to obtain the Diploma of Public Health, are referred to the announcements of Mr. E. Gooch, B.Sc., and of Mr. E. S. Weymouth, M.A.Lond., on page xl. of our present issue.

DR. RABAGLIATI'S letter is unavoidably crowded out of our present issue.

DR. F. (Oban).—The decisions of the Privy Council are not always reasonable. You are right in saying that ten articles were scheduled by the Pharmaceutical Society as poisons, but three, acetanilide, soluble salts of oxalic acid, and sulphonal were excluded by the Privy Council.

D. P. H. (Worcester).—The late Mr. Noble Smith took great interest in school hygiene, and devised a couch on which children could recline and study. It could be screwed up to accommodate any child.

IGNOBUS.—The Municipal Officers' Association has been in existence some twelve years and is in a strong position. We should advise you to join it and bring the matter before their notice.

W. (Dover).—Eau de Cologne can hardly be classed as a drug, and in any case it would be liable for duty. Under the circumstances it is better left behind.

SPA.—The trout fishing is said to be very good, and we believe this is not an angler's tale of the usual kind. The other advantages are as described.

BRADFORD.—The ordinary commercial substance, we believe, is never free from some trace of acid. Peroxide of hydrogen should always be kept in good strong bottles, or in those with a loose stopper, through which any oxygen formed may escape.

X. (Dundee).—The birth rates for the towns you ask about were, for the month of July, as follows:—Greenock, 34·5; Glasgow, 28·7; Leith, 27·7; Dundee, 26·9; Paisley, 26·8; and Edinburgh, 21·7. 7·6 per cent. of the births were illegitimate.

ANTIFLEXION.—The growth may be benign, but tumours arising from the external genitalia are generally malignant. You should certainly have a section of the growth cut and examined by a pathologist.

CHESHIRE.—Each medical inspector in New York visits the schools in his group and in a special room he examines all children suspected by teachers to have contagious diseases, all children who have been absent from school, and all cases indicated by the school nurse.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 12th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X Rays. Operations.

Vacancies.

Manchester University.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to the Registrar.

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles H. Byers, Secretary and House Governor.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

City of Birmingham Asylum, Rubery Hill, near Birmingham.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, &c. Applications to the Medical Superintendent.

Camberwell House Asylum.—Second Medical Assistant Officer. Salary £150 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent.

Manchester Children's Hospital, Pendlebury.—Assistant Medical Officer. Salary £100 per annum. Applications to the Secretary of the Hospital, Pendlebury, near Manchester.

Cardiff Union.—Assistant Medical Officer. Salary £130 per annum, with rations, apartments, attendance, and washing. Applications to Arthur J. Harris, Clerk, Union Offices, Queen's Chambers, Cardiff.

Great Northern Central Hospital, Holloway. — Pathologist and Curator. Salary £100 per annum. Applications to L. H. Glenton-Kerr, Secretary.

Leicester.—Resident Assistant Medical Officer (Poor Law Infirmary). Salary £120 per annum, with rations, furnished apartments, and washing. Applications to Herbert Mansfield, Clerk to the Guardians, Poor Law Offices, Leicester.

Sussex County Hospital, Brighton.—House Surgeon. Salary £100 per annum, with board and residence in the hospital, with washing. Applications to the Secretary.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C. Founded 1804.—Senior House Surgeon. Salary £100 a year, with board and residence in the hospital. Applications to the Secretary.

Bromyard Union.—Medical Officer required for No. 1 District.—Particulars of E. L. Cave, Solicitor, Bromyard. (See advt.)

Fermanagh County Infirmary.—House Surgeon. Salary £52 per annum. Applications to Mr. C. Wilson, Secretary. (See advt.).

Appointments.

GERATY, LAURENCE, M.R.C.S.Eng., L.R.C.P.Lond., Medical Officer of the No. 9 District of the Lincoln Union.

HARPER, FRANCIS MARGARET, M.B., Ch.B.Edin., D.P.H.Camb., Lady Assistant Medical Officer to the County Borough of St. Helen's, Lancashire.

JORDAN, ALFRED C., M.D.Cantab., Medical Officer to the Electrical Department of the North-Eastern Hospital for Children, Hackney Road.

NICHOLLS, FRANK J., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.Lond., Medical Officer to the London County Council Training College, Avery Hill, Eltham.

STOCKER, EDWARD GAVED, L.R.C.P.Lond., M.R.C.S.Eng., temporary Medical Officer and Public Vaccinator for the Clevedon District, Somerset, by the Long Ashton Board of Guardians.

TAYLOR, CLIFFORD J., F.R.C.S.Edin., House Surgeon to the Herefordshire General Hospital.

WHITE, GEORGE F., M.D.Dub., Certifying Surgeon under the Factory and Workshop Act for the Stanford-le-Hope District of the county of Essex.

Births.

McDOUGALL.—On Aug. 5th, at Benloyal, Woodcote Road, Wallington, Surrey, the wife of William Stewart McDougall, M.B., C.M., of a daughter.

Marriages

LATHAM—LARSEN.—On Aug. 23rd, at the Cathedral, Trondhjem Norway, Arthur C. Latham, M.D.Oxon., Physician to St. George's Hospital, London, son of P. W. Latham, M.D., late Downing Professor of Medicine, Cambridge University, to Ella Augusta Petrea Larsen, youngest daughter of the late Herr Peter Larsen, of Aarhus.

Deaths.

ADAMS.—On Sept. 6th, at Hove, James Adams, M.D., M.R.C.S., late of Barnes, in his 77th year.

SMITH.—On Sept. 5th, accidentally drowned while boating, Leslie Ernest Maule Smith, M.R.C.S., L.R.C.P., only son of Dr. E. and Mrs. Barratt Smith. Aged 24.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, SEPTEMBER 19, 1906. No. 12.

NOTES AND COMMENTS.

Swansea's New Asylum.

IT is a curious thing that during the last few months there should have been much trouble about the Welsh asylums. We have already commented upon the election of an asylum superintendent at Cardiff in which improper influences were alleged and much feeling exhibited, and also on the adverse report of the Lunacy Commissioners on the Joint Counties' Asylum where what is everybody's business is neglected because nobody can decide whose business it is. Now there is trouble at Swansea. Last week the General Purposes Committee of the Corporation met to discuss the question of the site of a new asylum which it proposes to build. A careful report from one of the Lunacy Commissioners was read in which the site was approved in a general way, if certain conditions were adhered to and certain additional suggestions carried out. The Chairman of the Asylums Committee moved that they should adopt the site, subject to a satisfactory report by an expert, and named a gentleman for the purpose. This name was opposed, and the Chairman of the meeting stigmatised a letter the gentleman in question had written to the Chairman of the Asylums Committee as "very nearly indecent," the expert being obviously anxious to demonstrate his own suitability for the job. Then followed an unseemly dispute which ended in the Chairman quitting the chair, and general unpleasantness all round. To those at a distance Welsh lunacy administration does not seem to be in a very happy condition, and allegations of improper influence are not calculated to increase public confidence.

Sanatorium Finance.

THERE is an element of tragedy about the reports of some of the sanatoria that are issued from time to time. At the beginning of what may be called the tuberculosis "boom," people were converted in large numbers to the gospel of fresh air and sanatoria and flushed with enthusiasm they started building sanatoria and giving donations. Throughout the country on rising knolls and breezy uplands rose comfortable buildings which were expected to restore to health and efficiency consumptive workers of all sorts and conditions, and counsels of caution were hardly heeded. A little worldly wisdom would have taught responsible people that after every excitement comes a reaction, and that when a reaction sets in every circumstance that can increase the depression is called in to account for it. Signs of such a reaction with regard to sanatoria are not wanting, and if we mistake not there are likely to be still more in evidence before a normal balance is established between expectation and accomplishment. At a meeting held at Bath on the 12th of this month, the affairs of the Winsley Sanatorium were discussed, and a highly unsatisfactory state of affairs was revealed. The Sanatorium is already £15,000 in debt, and requires £900 a year more than it is receiving to keep it going. Moreover charges of extravagance on initial outlay on building and dissatisfaction at the therapeutical value of the institution have apparently estranged sympathy, and at the best only 60 beds are provided for a population of one and three-quarter millions of people. At the meeting a resolution was proposed, and eventually passed, to raise £7,500 on mortgage in order to pay off the more pressing creditors, but it seemed to be generally recognised that unless far more liberal regular support was forthcoming the Sanatorium would find itself involved in serious financial difficulties. We sincerely trust that the locality will rise to the occasion and remove the reproach of niggardliness that lies upon it; but the incident is not without significance, and should be carefully noted by those who are thinking of embarking on similar enterprises.

Conveyances and Small Pox Patients.

THERE has been some unpleasantness at Limehurst, near Ashton-under-Lyne, because a doctor allowed a lady patient whom he found to be suffering from small pox, to walk to the hospital. On the face of it such a proceeding wears the appearance of negligence, and the Limehurst District Council wrote an indignant letter to the doctor demanding an explanation, and pointing out that he was liable to prosecution under the Public Health Act. The doctor replied that the patient in question absolutely refused to go to hospital in the van, and that he as resolutely opposed her going in a cab. Here was a dilemma. He was determined to get her into hospital however, and the best course under the circumstances was to make her walk; so recourse was had to the old device—*solvi tur ambulando*. As the route lay through a quiet country lane, and no one was met on the way, we really think the Council might write to congratulate the doctor on his tact in overcoming the difficulty of getting the

patient to hospital, instead of holding solemn conclaves and breathing out threats because of a technical irregularity in the course he adopted. The public seldom appear more foolish than when they are brought into contact with the question of infection; partly through ignorance and largely through fear, they generally manage to do, say, or write grotesque things which they would hardly do in their sober senses.

Small-pox in Out-Patients' Rooms.

WHAT, for instance, is the right course for a physician to take when he sees a man with small-pox seated on a bench with other out-patients quietly waiting their turn? In some of the larger and more modern hospitals there are special isolation rooms, but such is not always the case, and the choice of what is to be done lies between two evils. This particular situation presented itself to a medical friend of ours some little time ago, and with admirable promptitude he called the small-pox patient out and walked him up the middle of the street to the nearest ambulance station. Legally, no doubt, the doctor was wrong, and some fussy councils would have been delighted of the occasion to prosecute him; but common-sense and legal obligation do not always point the same way. At any rate this course was better than that adopted, or—which is not always the same thing—said by the patient to have been adopted, by a practitioner in London a few years back. The man was summoned for exposing himself in the Underground Railway while in an infectious state, and his story was that he had been to a doctor who told him he was suffering from scarlet fever and should go to hospital. The best way of accomplishing this was discussed, and it was finally decided that he should travel by the underground railway because the quantity of sulphur in the atmosphere would be sufficient to emasculate any germs that might emanate from him.

LEADING ARTICLE.

BRENTFORD HOSPITAL SCANDAL.

WE were unable to comment last week on the scandal at the Brentford Isolation Hospital owing to the fact that that issue was devoted to the special interests of students, but the incident is one that is worthy of special attention. It appears that three children of one of the Corporation employés at Ealing were inmates of the hospital in question, and the father was so dissatisfied at the treatment they received that he wrote a public letter of complaint to the Council. The Council deliberated over the subject of this letter and made their inquiries with closed doors, so that whatever happened at their meeting can only be guessed at by their decision to dismiss the superintendent nurse and severely to censure other officials. It is asserted in various papers that there have been many other complaints against this hospital from time to time, that its administration is badly conducted, and that representations were made to the Local Government Board.

In one respect, therefore, it seems that the Brentford Isolation Hospital is like a good many of its class, namely, in forming a frequent source for complaint and dissatisfaction among those whom it serves, and if we turn to the letter of the complainant who raised the recent to-do, we find a typical example of these complaints. The first is, that one of his girls was sent home from the hospital after scarlet fever "as properly cured and disinfected on July 3rd," and that on July 11th his other two children were found to have scarlet fever and stood in need of removal to hospital. Although we are not informed how long the first patient was detained, it is perfectly reasonable to assume that she passed the usual period of six or eight weeks there, and was "disinfected" when she came out, but that, like some four or five hundred similar cases in London every year, she proved to be infectious although no sign was visible on her discharge. The father asserts that the child "peeled" after her return home, but it is well recognised not only that secondary peeling may go on for many weeks after scarlet fever, but also that there is no evidence that such desquamation is infectious. The complaint, then, so far, if the facts be as we assume, should not be against the administration or the officials, but against the disease from which the child suffered, for its not conforming to the regulations which are laid down for it in text-books, and on which the isolation hospital system was founded. The next point in the father's letter is that the children who were infected by their sister were, on removal to hospital, placed in a ward where there was an outbreak of measles, and that one child caught this disease and died. Here, again, we have a substantial complaint; no one can deny the hardship, and no one can compensate the father for the loss of his child. At the same time—we speak in ignorance of the actual accommodation—in isolation hospitals where the number of wards is relatively small and a large proportion of the patients are children, it often happens that there is no suitable accommodation, except in a ward where whooping-cough, measles, chicken-pox, diphtheria, or some other infection is present. If it is anybody's fault it is that of the ratepayers for not providing sufficient accommodation for every disease and combination of diseases that child-flesh is heir to. The other two complaints, that the child was allowed to stay too long out of bed, and that no nurse "walked" the ward during the night, are (if true) either the result of improper supervision or to that frequent cause of trouble in isolation hospitals—under-staffing. Where numbers rise and fall in isolation hospitals as they continually and constantly do, the task of keeping the staff at a level sufficient to cope with emergency and not too high to call forth the wrath of economists, is an invidious one for even the most accomplished administrator. The grand rule that guides the management of many of these hospitals is to muddle along as well as possible till a scandal arises, and then to dismiss an official. Whether this

was so at Brentford or not we cannot say on the evidence available, but we think we have said enough to show that, so great are the difficulties in satisfactorily managing these hospitals, it is a grave question whether it is wise to continue to spend the enormous sums their upkeep entails in the indiscriminate removal of all scarlet fever cases. The Brentford case gives point to what we have so often urged, namely, that the moment is ripe for a full inquiry into the results of the working of the system.

NOTES ON CURRENT TOPICS.

Law for Lawyers and Law for Doctors.

Some weeks ago, under the above heading, we commented upon certain cases in the police and criminal courts illustrating the law as it affects illegitimate practice in the legal and medical professions respectively. If the underlying facts could be impressed upon the public and Parliament it is impossible to believe that the present state of things would be allowed long to continue. A case heard at Marlborough Street Police Court on Tuesday in last week once more showed how complete is the protection afforded by the law to lawyers and to the public in the matter of practice by the unqualified. A man was fined £5, with £3 3s. costs, for sending a letter demanding payment for a debt and containing expressions which might be construed to imply that the writer was a solicitor. Under medical law no equivalent prosecution is possible. Unless a quack is foolish enough to assume a title distinctly named in Medical Acts, he may adopt any method he chooses to lead the public to take him for a fully qualified man; and there are hundreds of fraudulent quacks throughout the country practising under such false pretences. Many, or most of them, publish advertisements which lead their readers, and even educated readers, to look upon them as qualified medical men. No one has any power to interfere with these rogues so long as they do not violate common law; and there exists no public prosecutor and no body like the Law Society to take proceedings, even when flagrant violation of Medical Acts is committed. It is for the complete exposure of these anomalies that the appointment of a Royal Commission is so urgently demanded.

The Coroner's "Special" Pathologist Question.

Many obstacles have arisen in the spirited defence of their professional interests by the medical practitioners of South London against the arrogant inroads of a certain coroner, and the particular policy of the London County Council in advocating so-called "expert" pathologists. Perhaps one of the most serious reverses to the movement has been the decision of Mr. Cockerton, Auditor of the Council's accounts, to the effect that the disbursements made by Mr. Coroner Troutbeck in payment of Dr. Freyberger were legal. It is well to bear in mind, however, that Mr. Cockerton added his opinion that the Coroner's Act of 1887 never contemplated the employment of a special pathologist in the manner adopted by the coroner. He therefore recommended the passing of an amending Act, but whether in the interests of the Council or of the medical profession is not clear. The *South London Press*, in commenting on the matter, says naively that the incident may now "be said to be closed." With all due deference our worthy contemporary may be assured that there is little chance of the incident ever being closed except on a basis of ordinary commonsense justice and respect for the rights of an honourable profession.

Postage Stamp Paper for Cuts.

The history of popular remedies has yet to be written, but should it ever emerge into the light of day it will bristle with a grim host of tragedies. Medicine herself has, indeed, thanks to the genius of Lister, recently grasped the ideal treatment of wounds by the exclusion of harmful bacteria. It is, of course, now open to the truly enlightened housewife to keep at hand some simple antiseptic dressing, such as Condy's Fluid, weak carbolic lotion, boric ointment, and boracic acid lint and cotton wool. By the use of such remedies all ordinary cuts and other small injuries involving the skin may be treated with confidence as within the range of legitimate household surgery. If ordinary sticking-plaster, unsterilised rags, and other germ-laden dressings be applied, the results from even a trifling cut may be disastrous. Abscesses, blood-poisoning, lockjaw, prolonged ill-health, and rapid death may ensue from a tiny septic cut or abrasion. A few weeks since an inquest in point was held at Oxford upon the body of an elderly lady who had knocked a piece of skin off one of her hands, and dressed the wound with a piece of the gummed edging of postage stamps. The arm was poisoned, and she died within a few days. Postage stamps are peculiarly liable to become septic and to convey deadly germs: a fact that cannot be too widely known to the public who find in it a popular substitute for sticking-plaster.

Mortuary Porters and Post-mortem Examinations.

The familiar question of what amount of help medical men may fairly look for at the hands of mortuary attendants has cropped up in an acute form at Cardiff. A member of the local Health Committee recently startled that body by alleging that in numerous cases of *post-mortem* examinations, for which medical men were paid, the bodies were opened and the organs cut out and placed on the table by the caretaker, who afterwards replaced the organs and sewed up the body. This statement has been emphatically denied by the caretaker himself, as well as by the district police surgeon and other prominent medical men. So far as Cardiff is concerned, the matter will doubt-

less be impartially sifted. As regards the general question, it is hardly necessary to point out the absolute desirability of the medical man carrying out with his own hands the whole of the *post-mortem* except, perhaps, the restoring of organs and stitching up of the body. Any other course might obscure or destroy valuable evidence upon which reputation or even life might depend. Some of our readers may recall an incident of the kind in which a much talked of London "expert" was concerned. The case was one in which the interest centred upon a tracheotomy wound The pathologist arrived on the scene shortly before the opening of the inquest, and all the organs, including the trachea, had been removed, and neatly arranged on the table by the porter! In a criminal inquiry an act of that kind might be quite enough to invalidate all evidence arising from a *post-mortem* examination.

Lord Kitchener and Typhoid Fever.

AN excellent example has been set by Lord Kitchener in India in appointing a Standing Committee on Enteric Fever, but we hardly expect that its influence will extend to Pall Mall. The value of proper hygienic knowledge in the prevention of disease is dawning very slowly on the British Army authorities, but in India where intelligence is a passport to high places and the army has to be kept on a businesslike footing, it has long been recognised that money invested in the proper clothing, feeding, and care of soldiers is well-laid out. Enteric fever, it is curious to reflect, was always supposed to be non-existent in India, and even now there are those who cherish a distinction between "tropical typhoid" and temperate zone typhoid. But, however it be regarded or classified, there is no doubt that enteric fever is a great danger to Europeans in India, especially to those who are young and newly-arrived. The attack and mortality rates among the British troops are still unreasonably high, and it is good news indeed that systematic effort is to be made to reduce them. Cholera has lost nearly all its terrors for the white population of India, and there seems no good reason why enteric should not follow suit. Lord Kitchener addressing the first meeting of the Committee, spoke principally on anti-typhoid inoculation, which is regarded as a settled practice by the medical authorities in India. The difficulty in many cases is to get the soldiers to allow the inoculation to be performed on account of the initial pain and inconvenience, and Lord Kitchener asked his hearers to consider carefully whether it would not be possible to make the process less painful either by actual improvements in it or by using smaller doses, and reducing the length of the period of immunity gained. He also commended to their consideration the important question of examining the blood of men who had had enteric, and were possibly disseminating the disease by retaining the bacilli in their organs. The Committee, we may be sure, will have strong support in any action they advise from a man who carries efficiency to the point that Lord Kitchener does.

The Marienbad Cure.

"TURTLE," said Lord Beaconsfield, "makes all men equal," and the same assertion can be made of those who seek to be patched up after a superfluity of turtle. King and commoner alike find benefit from a "cure," and they can both avail themselves of it on one condition, namely, that they pay the piper; so at Marienbad, Homburg, and Aix they meet on the common level of suffering humanity. But, knowing the natural tendencies of mankind, one can be certain that at the spa where the King gets the most good, his loyal subjects will find that they, too, get on best. Therefore the lamentations of the English spas, of which so much is to be read in the newspapers now that the season is closing, are no doubt justified. It is ridiculous to suppose that the cleansing virtues of sodium sulphate are more efficacious at Carlsbad than at Harrogate or that iron benefits chlorosis more at Aix than at Tunbridge Wells, especially as it is possible when necessary to drink the water of any one spa at any other. The popularity of Continental resorts is regrettable from the point of view of British capital invested in home spas, but indignant letters to the papers will not alter the fact. No doubt spa-caterers at home have a good deal to learn both as regards the judicious management of their guests and the accommodation of charges to pockets; but, after all is said and done, the matter is one of habit and fashion, and till these are broken through, the British spa, woo it never so wisely, will not attract the host of livery and obese plutocrats which throng the Continental resorts. Oliver Wendell Holmes has said that "habit is an action in present circumstances from past motives," and till the habit of being cured at home is formed, mankind, impelled by past motives and desire to drink solutions of Epsom salts next a Russian princeling or German baron, will continue to go abroad when it wishes thoroughly to "enjoy" its bad health.

Scarcity of Medical Men.

A NOTICEABLE amount of correspondence has been going on in various journals about the scarcity of doctors, and we are sure that a good many practitioners wish that the scarcity existed in fact as solidly as it does in the imagination of the writers. A walk down the chief streets of an ordinary town should, we would fancy, tend to undeceive any unbiassed person on the score of medical scarcity. No doubt every trade and profession as a whole is apt to take a pessimistic view of the competition with which it finds itself faced, but this much at least may be said, that the public may rest assured that they never need want for doctors, and good doctors, in any part of the British Isles. It is equally undeniable that if competition were a little less keen, the status and remuneration of medical men would be much improved, not in the subordination of the public interest to the medical, but in the increased opportunities for the good work and culture that would be possible for the medical men. Many now have little leisure for self-improvement and the advancement of their own knowledge and dexterity,

owing to the difficulty of making a living out of the small fees they receive, and such a state of affairs cannot be considered fully advantageous to their patients. The scarcity of doctors, if it ever exist, would soon rectify itself if the prospects of doctors were improved.

The Sources of Government Lymph.

In our columns this week will be found some letters which have passed between Sir William Collins and the President of the Local Government Board as to the sources whence the Government supply of vaccine lymph is derived. In the House of Commons on June 28, Sir William Collins asked Mr. Burns for a return showing the original sources of the vaccine lymph which had been, or now is, in use; but this return was refused, and Sir William was asked to put another question on the subject. The reply to this further question was far from conclusive, and in pursuit of his object Sir William Collins opened the correspondence which we now publish. The point at stake may seem at first sight an academic one, but if it be closely regarded, it will be seen to be not without interest, both scientifically and politically; scientifically because of the difficulties that attend the diagnosis of true vaccinia in animals, and politically because of the controversial utility to opponents of vaccination of this admission by the Government that they are unacquainted with the ultimate sources of the lymphs they issue. The strength of the prejudice against vaccination which exists in many parts of the country is hardly realised by those in authority, it has long passed out of the domain of reason and entered that of passion. Now it is the business of statesmen, if they wish to reconcile people to the vaccination laws, to remove from their path every obstacle, real or imaginary, and we hardly think the Local Government Board are to be congratulated on the way they emerge from this correspondence. They doubtless took the most detailed care in selecting the sources of their stocks to make certain not only that they had lymph free from extraneous contamination, but also that it was of proved efficiency, and we quite believe that the lymph actually in use now is good and efficient vaccine lymph; but why, it may be well asked, go to Cologne and to other Continental resorts for this lymph? If there be any peculiar efficacy in their strains it should be capable of being easily explained, and it is a pity that the department do not see their way to do so.

"Silly Season" and the Medical Profession.

The silly season has, as usual, produced a crop of attacks on the medical profession. Year after year, irresponsible scribblers are able to earn an honest or dishonest penny by sensational articles which suggest that one or other branch of our profession is composed of unscrupulous scoundrels. One year we learnt that it is the custom of general practitioners to act on commission as touts for undertakers, if not indeed to provide material for the industry of that class. This year, a gentleman, who signs himself "Hew Ronald" discourses glibly in the *Sunday Chronicle* of "How Sane Men and Women drag out their Lives in Private Asylums, whilst Rogues batten on their Fortunes." Mr. Hew Ronald seems to be rather unfortunate in his friendships, since he boasts of having quite a number of friends in these deplorable circumstances. The natural thing for Mr. Ronald to do would be to draw the attention of the Lord Chancellor or the Inspectors in Lunacy to this scandalous state of affairs, but doubtless it pays him better to write two columns on the subject to a weekly paper. In these columns we hear much of "venal and unscrupulous doctors," and from them we learn that "there is a powerful section of the medical profession who are directly interested in depriving sane people of their liberty." On the other hand, we breathe again at the admission that "there are good mad doctors and good asylums." According to Mr. Ronald, there is nothing easier than to lodge a sane person in an asylum, and nothing more difficult than for that person to get out. It would, perhaps, not be irrelevant to suggest that while there are good journalists and good papers, there are also "venal and unscrupulous" writers who are willing to do a "dirty job" not perhaps for an "enormous fee," but for the modest and traditional penny-a-line.

In the special Army Order promulgated on Saturday last it is appointed that six of the most meritorious officers of the medical service on the active list shall be named the King's honorary physicians and six honorary surgeons. On appointment as an honorary physician or surgeon an officer under the rank of colonel in the Medical Corps may be promoted to the brevet rank of colonel. On retirement an officer must relinquish the appointment of honorary physician or surgeon.

PERSONAL.

Last week, Dr. Wolfenden, of London, with his two sons, had a narrow escape on a runaway motor, while touring on the Welsh mountains. The car was smashed to pieces, but the only serious injuries reported are a broken collar bone in one of Dr. Wolfenden's sons, who was pinned under the car, and a dislocated shoulder sustained by the chauffeur.

The Bishop of Bristol will deliver the inaugural address and present the prizes to students at the opening of the winter session of St. George's Hospital Medical School on October 1st.

Dr. Morris Travers, Fellow of London University, and Professor of Chemistry at University College, Bristol, has been appointed Director of the Indian Institute of Science, which is to be established in Bangalore.

The Inaugural Address at the Meath Hospital Dublin, of the Session 1906-7, will be delivered on Monday, October 8th, by Sir Lambert H. Ormsby, senior surgeon to the hospital.

On the occasion of his departure from Blagdon after many years of practice, on account of failing health, Dr. Richard Brown, M.B., was last week presented with a silver bowl and a cheque for £233 by his friends in the neighbourhood.

The King is reported to have benefited much in health from his recent stay at Marienbad.

Dr. Howard A. Kelly, of Johns Hopkins Univ. arrived in London this week, en route for the Quater Centenary at Aberdeen.

A CLINICAL LECTURE
ON
TECHNIQUE AND INDICATIONS FOR LUMBAR ANÆSTHESIA.

By R. LUCKE, M.D.,
Specialist in the Diseases of Women.

THE attempts to produce sufficient diminution of sense of pain for purposes of operation in the lower half of the body by the injection of anæsthetics into the spinal canal date from 20 years ago. In 1885 Corning tried to attain this object by injecting cocaine between the 11th and 12th dorsal vertebræ, and his technique differed from that usual to-day in that independent of the choice of spot he avoided injecting into the spinal canal itself; he injected therefore extradurally, a precaution that was justified by the choice of the site of injection. Only in 1894 did Corning inject the cocaine into the spinal canal itself, and at a spot where injuries to the cord were no longer to be feared, *i.e.*, between the 3rd and 4th lumbar vertebræ. In Germany, Bier before all others has done good service in working out the process; he experimented on himself, and in spite of results not altogether satisfactory at first, did not cease his attempts to perfect the process. In France also the procedure awakened great interest mainly through Tuffier, which, however, was speedily extinguished owing to an impression that bad results accompanied and followed the injection of cocaine. It was these bye-effects that mainly stood in the way of the general introduction of lumbar anæthesia, and we find therefore a series of experiments with other and less poisonous preparations in the place of cocaine, for example, B. eucain, tropacocaine, and many others. Both the substitutes mentioned have found employment, especially in Austria. It does not appear that perfectly satisfactory results have been obtained with these preparations, but they are praised by many. It is difficult to form a judgment on them without a personal experience. An advance in the material to be employed was made in the introduction of stovaine, which was synthetically prepared by Fourneau. This was markedly less poisonous than cocaine, and also showed good anæsthetising properties. In France it was first employed by Chaput; it was introduced into Germany by Sonnenburg.

Quite recently a considerable improvement has been made in the procedure by the addition of adrenaline to the injection fluid. This substance, which, thanks to vasomotor constrictor power, lengthens the period of resorption, allows of very advantageous modifications in the employment of lumbar anæsthesia.

The technique of lumbar anæsthesia is covered as a whole by that of Quincke's lumbar injection for diagnostic purposes. In puncturing some practice is required as it is not only necessary to get into the spinal canal, but to do it with dexterity and at the right spot.

To bring to mind the topographic anatomy of the region implicated in lumbar anæsthesia, it is above all important to remember that the spinal cord with its *conus terminalis* finds its end somewhere about the level of the arch of the second lumbar vertebra, whilst the dural sac descends to the level of the second sacral vertebra. Over this stretch therefore a needle thrust in will not touch the cord itself under any circumstances, but passes between the bundles of nerves passing almost parallel to each other from above downwards—the cauda equina. These caudal bundles run in two chief cords right and left, leaving a free space in the median line. This space is of special importance for the direction of the needle on puncture.

The bony skeleton, at least under normal conditions, presents no special difficulties in regard to puncture, as the spinous processes do not as in the dorsal vertebræ form a sort of tiled covering but lie more perpendicularly to the spinal axis, and besides this a considerable widening of the space between the arches of the vertebra may be brought about by powerful flexion of the spinal column.

Between the dural sac and the bony spinal canal a more or less well developed cushion of fat lies in which the plexus of veins is embedded. The openings between the vertebral arches and —in adult very strongly developed—the spinous processes are closed by masses of ligaments.

The needle in its course, therefore, passes through the skin, the subcutaneous connective tissue, the muscular structures on the ligaments of the dorsal vertebræ, and passing through these, through the epidural fatty tissue with its venous plexus and the dura into the dural canal where the fibres cauda equina mostly escape the advancing needle.

The spot for puncture is determined, as the counting of the spinous processes is not easy with a well developed fatty covering, most simply by taking the level of the cristæ ilii at their highest point. This line cuts the apex of the fourth lumbar spine.

In performing the puncture it is best to choose the right lateral position on the operating table. This position is much preferable to the sitting one, as sudden fainting of the usually nervously excited patient is not beyond the range of possibility, and moreover it favours a better fixing of the body. The patient's legs are drawn up and the spine is flexed as much as possible. The flexure of spine is increased and fixed by an attendant standing on the ventral side, who encircles both the head and lower extremities in his arms and tries to bring them near together.

In carrying out the puncture the most rigid asepsis is of course necessary. After suitable preparation of the patient, and of the hands of the operator, the puncture is made usually between the third and fourth lumbar vertebræ, thus, therefore, in the third interspace; to puncture lower is not only aimless but it is disadvantageous as regards the effect. The puncture may be made between the second and third arches when a

specially high reaching anæsthesia is desired, or if the puncture in the third interspace is not successful. One half to one cm. on the side of the spinous process, or, in the lateral position of the patient, immediately below it, Quinke's canula is thrust forwards, and a little towards the median line and about 5 to 6 cm. in depth, until you feel, as you generally do plainly, that the needle has passed into a hollow space. The trocar is now withdrawn. If clear cerebrospinal fluid now escapes the canula is in the right place. About 1 ccm. is allowed to flow, and then the syringe partly filled with the medicament is attached to the canula, the plunger of the syringe is then withdrawn until the quantity of cerebrospinal fluid about equals the quantity of the solution in the syringe, and the two fluids are then very slowly injected into the canal. The canula is now removed with a jerk, and the minute wound is covered with gauze and sticking plaster. The patient is now placed on his back and the onset of the anæsthesia awaited. Dönitz has lately advised that the puncture should be made in the middle line, that the needle should penetrate as far as the canal, and pass into it only after the trocar has been withdrawn. This method has the great advantage that the spinal fluid is seen to flow at once, and there is not so much danger of doing mischief by puncturing too deeply.

The whole procedure is only slightly painful, it can be made quite painless by anæsthetising the point of puncture with chloride of ethyl, as the lower layers of tissue have scarcely any sensation. Care must be taken, however, not to puncture the periosteum of the vertebræ, by going too high or too low, or penetrating too deeply.

A number of authorities advise puncture into the middle line immediately below the top of the spinous process, and pushing the needle in perpendicularly. That is, however, as you are accustomed yourself, the puncture laterally is just as safe and easier, inasmuch as the canula has to pass through denser ligaments in the adult. In lateral puncture also the canula has a wider space to play in; again the shape of the spinous process varies, especially in regard to its prolongation downwards, and which sometimes almost covers over the space between the arches. The objection occasionally made to the lateral puncture, that the danger of direction inwards of the needle is uncertain, that it must vary with the thickness of the overlying layers, is in my opinion baseless. The bony opening in question is so wide transversely that the slight difference in the angle could not be of any importance. You can convince yourselves of that by comparing various skeleton vertebræ. In my experience also the technique is easier for the unskilled than median puncture between the spinous processes. On the other hand it cannot be disputed that in puncture in the middle line the needle arrives with more certainty into the space between the two bundles of cord, into which *lege artis* the anæsthetics should be injected.

Regarding the preparation of the instruments one point comes into consideration. Both canula and injection syringe should be washed with plain sterilised water after taking them out of the soda solution, before being used. This is especially indispensable when stovaine is used, as deposits take place with alkalies that lower its activity.

There are a number of conditions that render the carrying out of a puncture difficult. Amongst these is great restlessness, as met with in nervous persons, such are scarcely suitable for lumbar puncture; obesity again that makes it difficult to feel the spinous processes, and that may thicken the parts to be passed through up to 7 to 9 cm. In abnormal ossification of the ligaments puncture may be impossible, and also as in a case observed by the writer lumbar scoliosis; again on the other hand the canula may pass into the spinal canal without any appearance of cerebrospinal fluid and this in spite of all manœuvres. In these cases there is probably an obliteration of the dural canal, either pathological or based on congenital causes.

Independent of technical impossibility it may happen that in spite of the injection of the anæsthetic into the dural sac, owing to some want of power of the patient to react to the drug no action at all, or a much weakened one, takes place. According to some authorities patients with disease of the spine are apt to be refractory.

Apart from these cases one may as a rule look upon failure as caused by faulty technique. Here must be specially remarked, as was done also in the work issuing from Bier's clinique, that one must always see that the flow of cerebrospinal fluid into the syringe is *continuous* after removing the trocar. This continuous flow is a proof that the tip of the canula is in the free space between the two bundles of the cauda equina. If the fluid flows by drops only, the point has very probably got into one of the bundles, and it does not mix properly with the anæsthetic. In such a case one often sees the curious features of a one-sided anæsthesia. In such cases gravity is not the cause, as the anæsthesia may be on the left side when the patient is lying on his right, but an injection not between the two, but into a bundle of nerves does not diffuse itself readily and only the side reached reacts. This feature was noted in the work issuing from Bier's clinique.

It often happens that on removal of the trocar blood comes instead of cerebrospinal fluid; three different causes may account for this: either there has been hæmorrhage into the dural sac, this happens so rarely that it need not be taken into account, then the blood will be dark brown and remain so, and not clot with the cerebrospinal fluid, or a vein may be pricked, when the bright blood will soon clot, and after some waiting the fluid will be clear again, or lastly fresh blood may continue to flow, when it will be that the canula has entered the vein. So long as bloody fluid comes, no injection must be made, but the direction of the needle must be altered, or, better still, a fresh puncture may be made higher up between the second and third or first and second lumbar interspaces.

Regarding the indications for the employment of lumbar anæsthesia it may be observed that it is a method that should come into competition with general anæsthesia, and that even in its present state of development already does so. With this object it is a desideratum that it has no concealed dangers for the patient. The anæsthetics now principally in use, stovaine, novocaine, and alypin that now seems associated with them, have not the frequent serious concomitant effects of cocaine. By the addition of adrenaline the danger of paralysis mounting too high to the medulla is materially diminished; it has been successfully

attempted to prevent this by raising the pelvis after the injection. It is not beyond possibility even to render circular segments anæsthetic without participation of the lower extremities. In any case it is certain that so much has been achieved that without any considerable danger to life the human body can be rendered insensible to operative measure up to the level of the umbilicus and in many cases up to the ensiform cartilage.

Lumbar puncture comes into question in all operations on the lower extremities, on the perineum, on the lower part of the abdomen, for example, internal operations in appendicitis, herniotomy, sectio alta. Gynæcological laparotomies may be performed, but here experience must be gained on account of the general raised position of the pelvis employed. In laparotomies in the lower part of the abdomen we hear keen complaints of pain in the region of the stomach, when the intestines are dragged upon, and when the anæsthesia does not go very high. In operations between the umbilicus and ensiform cartilage the procedure is less certain, but with higher doses, for example stovaine 0·08 grm. with adrenalin, sufficient anæsthesia may be obtained. Moreover, if the anæsthesia is not quite sufficient a few drops of chloroform are enough to gain tolerance.

The great advantage of lumbar anæsthesia, as compared with general is the comparative well-being of patients after operation. As a rule vomiting and nausea are quite absent, as also the general prostration, and patients may even take food when the nature of the operation does not forbid it. The effect on the pulse also is absent, the patient not being stupified breathes more fully and deeply, and the danger of adspiration is avoided.

Lumbar anæsthesia is therefore above all to be recommended in old marantic individuals, when the pulse is poor, in cardiac diseases and especially muscular degeneration of the heart, in disease of the lungs, and, lastly, in drinkers, in whom general anæsthesia is hard to bring about, and withal disagreeable, and very large doses are often required, and the heart perhaps not sound. It is further to be recommended in all affections accompanied with symptoms of ileus, on account of the danger of adspiration, and aided by a semi-narcosis, or still better by a short administration of ether, whilst the intestines are outside. The indication is not so marked in operations in the upper part of the abdomen, the result here is not so certain; gastrectomies have been carried out well, but one has got the impression that local anæsthesia here would have done just as well. The method is sovereign in all operations on the lower extremities, the perineum and pelvis. Here one must not omit to point to the excellent results which have been obtained with lumbar anæsthesia in the repeated bloodless stretching of the nerve in sciatica (Telmann). In spastic conditions of the lower extremities the anæsthesia has not brought about any lasting good results.

Against all this there are a few contra-indications that must be considered if lumbar anæsthesia is not to fall into discredit. The injection should not be made in the case of children under fourteen. One must consider that the youthful organism is more sensitive, and with lumbar anæsthesia a certain amount of intelligence and self-control is required on the part of the patient that can never be looked for in children.

Nervous people also make it very difficult from their great mental excitement. Their moaning and restlessness in spite of the anæsthesia render calm performance of an operation very difficult; here the same conditions are present as in the young. Great caution is required when neuroses, even mild ones, are present—this caution arises not only from the surgical but also the psychiatric experiences of the author. One observes too frequently in such people in connection with even slight operations a very considerable increase in the psychical disturbance which is the more disagreeable as the hypochondriacal ideas coming forward are mainly directed to the part operated on. A patient operated on who, up to the time of the operation, was able to work, showed symptoms of a most severe traumatic neurosis, with complete inability to work, his hypochondriacal idea centred solely on a supposed injury to his spinal cord. If such cases are very rare they require the most urgent consideration. Lumbar anæsthesia is practically an operation affecting the spinal cord or its immediate neighbourhood, and among the public there is a great dread of spinal affections, and, as we know, this fear is the most lively amongst neurasthenics.

Another point deserves mention that does not belong to the series of indications, but rather to the physician's consciousness and his knowledge of the human mind. One should never forget that in contrast to general narcosis, in lumbar anæsthesia there is no shutting out of consciousness and that all major operations and especially mutilating operations cause a psychical shock. If the operation is one likely to cause great mental depression it will be correspondent to humanity to take from the patient the clear consciousness of what is taking place. With this in view it will be well to place an ether inhaler over his face, in which at first a small quantity of ether has been poured. He should be made to inhale deeply, so that the ether shall take a slight effect—a full unconsciousness is not required so long as the attention shall be drawn away from the operation itself, so that the demands of humanity may be satisfied without changing the mode of procedure.

The presence of pyæmia or sepsis is an absolute contra-indication of lumbar anæsthesia. A case related by Sonnenburg on the occasion of his first communication on the subject is very instructive. He lost a patient from ascending purulent meningitis in connection with the puncture in a case of multiple abscesses in appendicitis, and considered the complication to be due to the poison settling on the least resistent spot. This may be explained when one bears in mind that probably an extravasation of blood takes place within the peridural tissues. That this extravasation may be very easily infected where there is a general infection, goes without saying, and it is always to be borne in mind that we are quite powerless in an infection at this spot as compared with the situation in hypodermic injections.

Many authors see in disease existing in the spinal cord a contra-indication, but sufficient evidence on this point has not yet been collected. That spinal cases react easily to lumbar anæsthesia has already been emphasised.

If the contra-indications named are borne in

mind we have, in safe hands, a method of anæsthetizing that is free from danger and which may take its place in all operations from the umbilicus downwards. That this may be so depends in the first instance on the employment of a suitable substitute for cocaine, the three newest of which, besides cocaine and tropacocaine are stovaine, novocaine and alypine, and further in the addition of adrenaline preparations for the purpose of localising the action of the anæsthetic. Efforts to perfect the method are in full flow. Bier and his pupils have to be thanked for a number of technical improvements, and it may be hoped that lumbar anæsthesia may be still further developed.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by Sydney Stephenson, M.B.Ed., F.R.C.S., Ophthalmic Surgeon to the Evelina Hospital, the North-Eastern Hospital for Children, and Queen Charlotte's Lying-In Hospital, on "Diseases and Injuries of the Orbit." Lecture delivered in the University of Oxford on July 18th, 1906.*

ORIGINAL PAPERS.

THE METHYLENE BLUE REACTION OF RUSSO IN ENTERIC FEVER.

By J. D. ROLLESTON, M.D.,
Assistant Medical Officer, Grove Hospital.

RUSSO, of Catania, has recently introduced as a substitute for the diazo reaction a watery solution of methylene blue (1 in 1,000), for which he claims the following advantages: simplicity of technique, durability of the solution, and greater diagnostic value. Russo's test is performed by adding four drops of the methylene blue solution to 4 or 5 cc. of urine. (*a*)

Urines which are turbid from excess of urates or phosphates should first be filtered. If the reaction is positive, a uniform mint or emerald green colouration is obtained when the test tube is shaken. If the reaction is negative, the reagent does not change colour, or at most only a light green colouration results. Naturally between the two extremes various shades of colour obtain, as is the case in the diazo reaction.

The present paper is based on observations made on 70 cases admitted to hospital certified to be suffering from enteric fever. In 54 cases this diagnosis was confirmed by clinical evidence and Widal's test. The remaining 16 were found to have other diseases. Of the latter only four presented a positive reaction. One was a case of carcinoma of the stomach and peritoneum, two were cases of infective endocarditis, and one was a case of lobar pneumonia. All died within a few days of admission. A positive diazo reaction was also present in the secases. (*b*) The 12 negative cases were diagnosed respectively as follows:—

Lobar pneumonia	2 cases.
Influenza	2 „
Pleurisy	1 case.
Bronchitis	1 „
Appendicitis	1 „
Cirrhosis of liver	1 „
Cholelithiasis	1 „
Leucocythæmia	1 case
Erythema nodosum	1 „
Cerebral syphilis	1 „

Of the 54 cases of enteric fever, 44 were positive, 10 were negative. With two exceptions, which were cases of moderate severity, all the latter were very mild cases of convalescence when the reaction was first tried. The following shows the two reactions in cases admitted at various stages of the disease:—

	Methylene Blue Reaction.		Diazo Reaction.	
Cases admitted in	Positive.	Negative.	Positive.	Negative.
1st week	7	1	6	2
2nd „	15	4	8	11
3rd „	15	0	10	5
4th „	5	1	1	5
5th „	2	2	0	4
6th „	0	2	0	2
Total	44	10	25	29

The dates at which the reactions became finally negative are shown below, the fatal cases having been excluded.

	Methylene Blue Reaction.	Diazo Reaction.
1st week	0 cases	0 cases.
2nd „	4 „	7 „
3rd „	11 „	11 „
4th „	12 „	2 „
5th „ and later	11 „	0 „
Total	38	20

It is evident from the above figures that the methylene blue reaction is more constant and more persistent in enteric fever than the diazo reaction. That disappearance of Russo's reaction coincides more closely with the commencement of lysis, and that, therefore, *cæteris paribus*, a negative methylene blue reaction is a surer sign of convalescence than a negative diazo reaction, is shown by the fact that in all the 38 cases in which Russo's test was employed the two events occurred in the same week; whereas in the 20 cases in which the diazo reaction was concurrently used, in 14 the two events occurred in the same week, and in six lysis did not commence till the week following the disappearance of the reaction.

The two reactions resemble one another, in that before disappearing entirely there is usually a diminution in their intensity, the successive grades in the methylene blue reaction being conveniently designated by the letters M. B. R. +, M. B. R.—, M. B. R.— —, which correspond with shades of colour varying from a deep green in the first case to a light green in the second, and a decided blue in the third. Both reactions before becoming finally negative may be occasionally positive. Another point of resemblance between the two reactions is seen in their occasional disappearance in spite of aggravation of the general condition. This indicates the supervention of a secondary infection or impermeability of the kidneys to the colouring matter. Thus in three cases which, though the two reactions had become negative, the patient was obviously worse, one died of lobar pneumonia, one of perforative peritonitis, and one of hæmorrhage.

On occurrence of pyrexia in convalescence from enteric fever, in the absence of enlargement

(*a*) Metropolitan Asylums Board Annual Report, 1905.
(*b*) The occasional presence of the diazo reaction in these diseases is noted by Rivier (*loc. cit.*).

of the spleen or of a fresh outbreak of rose spots or other obvious physical signs, determination of the nature of such pyrexia may be a matter of no little difficulty. The diazo reaction is often a valuable guide, but in some cases of definite relapse it may fail to be positive. In such cases Russo's reaction is a more delicate test, since it often becomes positive again, while the diazo reaction remains negative. Thus in ten cases of relapse the diazo reaction which had previously become negative became positive again in three cases only; while Russo's reaction became positive in seven cases. It is noteworthy that those relapses in which the diazo reaction became positive again were more severe than those in which Russo's reaction alone was positive; while those in which both tests remained negative, the pyrexia was of a shorter duration still.

As with the diazo reaction a positive result may be obtained at a very early stage of the disease before Widal's test gives definite results. In one of my cases a positive methylene blue reaction appeared as early as the second day, though the diazo reaction in the same case did not become positive till the fifth.

Contrary to what is stated by Russo, I have found the methylene blue reaction positive in several cases of scarlet fever, lobar and broncho-pneumonia. I have also found it occasionally, though exceptionally, present in diphtheria and serum eruptions. Like the diazo reaction it is almost always present in measles. It was positive in 18 out of 20 cases in which I was employed.

Conclusions.—(1) Russo's reaction persists longer in enteric fever than the diazo reaction.

(2) The disappearance of Russo's reaction corresponds more closely with lysis than does the disappearance of the diazo reaction.

(3) In relapses, a positive Russo's reaction is more frequently found than a positive diazo reaction.

(4) The diagnostic value of Russo's reaction is similar but not superior to the diazo reaction.

PERSISTENT UNILATERAL HEADACHE DUE TO NÆVOID CHANGES IN THE ANTERIOR EXTREMITY OF THE MIDDLE TURBINAL BONE.

By WYATT WINGRAVE, M.D.,

Pathologist (lately Physician) to the Central London Throat and Ear Hospital.

THE pathogeny of severe focal headache is somewhat speculative, and this case is recorded partly for its instructive and definite morbid anatomy, but also because it affords an explanation for the occasional want of success in treating the middle turbinal body by cautery and local depletory measures for symptoms attributed to hypertrophy of that structure.

The patient, a healthy looking male, æt. 38, sought relief for severe and persistent frontal pain of three months' duration, dating from an attack of influenza. The pain was referred to the left supra-orbital and frontal regions extending to the vertex and occasionally to the corresponding eye. It varied in severity, but never left him, and was at times so acute as to interfere with his clerical duties and to cause him much anxiety. There were frequent attacks of coryza, which generally afforded partial relief, and he had been treated for migraine and hay asthma.

He was an enthusiastic athlete, of regular habits, temperate in tobacco and alcohol, but thought that he was gouty and had a tendency to piles. His only illness of any importance was influenza, from which he had suffered several attacks, the last one leaving a persistent nasal catarrh which had, however, nearly disappeared, although the pain had not diminished in spite of treatment.

Upon examination the right nostril was found to be quite free, but the left breathway was distinctly less in volume, due in part to a slight septal deviation, but chiefly to a marked hypertrophy of the left middle turbinal, which completely blocked the meatus. Probing was very painful, but yielded no evidence of bone lesion, and there was no sign of pus. Under cocaine the turbinal became pale, but diminished only slightly in size.

On transilluminating, the frontal and maxillary sinuses were found to be perfectly clear and symmetrical; still it was felt that the unilateral pain, together with the history and local signs pointed to some sinusal trouble probably due to drainage obstruction.

Local sedatives, general depletion, and bromides for a week affording no relief, the anterior end of the middle turbinal body was removed under alypin and adrenalin chloride by means of a Krause's fine wire snare which cut through the bone with ease. This was followed by free hæmorrhage lasting about fifteen minutes, but the pain gradually ceased and in the course of half an hour he left for home perfectly comfortable. No discharge of any kind beyond bleeding attended or followed the operation, and subsequent examination revealed no evidence of sinusal trouble. He made a rapid and complete recovery, six months later reporting that he had experienced no return of pain and enjoyed complete freedom from any "running" from the nose.

The part removed was about the size of a large haricot bean measuring 15 by 12 mm. On microscopic examination the mucous membrane appeared normal, but the bone cancelli were found to contain very thin vessels fully distended with blood and pressing on the walls. There was no evidence of lymphocyte infiltration nor any osteoplastic activity such as is usually found in inflammatory sinusitis involving the bone. The walls of the distended vessels were very thin, consisting only of epithelioid cells, in striking contrast with the arteries which as seen in the adjacent cancelli were quite normal. The condition which is strongly suggestive of a nævoid state, differs entirely from cavernous distension of the erectile tissue so common in the posterior end of the inferior turbinal, a state which involves the mucous membrane only and not the bone (*a*). Part of the bone was pneumatic and lined with normal mucous membrane, continuous with that of the ethmoid cells, a condition often found in hypertrophy of this part, and somewhat loosely described as "cystic turbinal."

(*a*) "Turbinal Varix," *Lancet*, June, 1894.

Although a moderate degree of congestion both periosteal and endosteal is often present in sections of removed middle turbinals, in this case it was exceptional, and together with the coincidental disappearance of symptoms on its removal, it may reasonably be interpreted as possessing a causal relationship. The morbid condition may be regarded as a passive nævoid process involving the spongy bone and bearing no resemblance to any inflammatory process such as rarefying osteitis, necrosing ethmoiditis, or suppurative sinusitis.

The association of the middle turbinal body with headache and many reflex phenomena is familiar to all rhinologists, likewise its anatomical relation to the hiatus semilunaris, which plays so important a role in drainage and ventilation of the accessory sinuses of the nose, but in the former connection, treatment has for the most part been restricted to cautery and other applications to its mucous membrane only; removal of the anterior end including the subjacent bone is more usually resorted to as part of the radical treatment of the sinuses, or, at all events, an essential preliminary.

The morbid anatomy of the case illustrates the inexpediency of persisting in the treatment of mucous membrane only, when it fails to afford relief at once. The fact of its having already failed in this case influenced not a little the adoption of the more radical course of dealing with the bony structure.

The operation is so extremely simple and quick that there is no necessity for a major anæsthetic, and punch, forceps, scissors, &c., are quite superfluous, for when the anterior end of the middle turbinal is sufficiently enlarged to require removal, a fine wire snare pushed well upwards and backwards will readily engage it and when gradually tightened will cut clean through both bone and mucous membrane. Care must be taken (1) to avoid simply stripping off the mucous membrane, which may happen if the turbinal be not properly engaged, and the snare not sufficiently pressed upwards; also (2) not to exert any dragging, twisting, or tearing force, since in patients over æt. 40, the ethmoid bone is extremely brittle and "biscuit"-like owing to senile osteoporotic changes in the bone. This caution applies equally to the removal of polypi in those of advanced years.

Note.—Since writing this report a paper has been read by Dr. Smurthwaite on "Headache Connected with Enlarged Middle Turbinal" Similar treatment is advised, but the pathology is different.—W.W.

PROPOSED STERILIZATION OF CERTAIN MENTAL DEGENERATES.*

By ROBERT R. RENTOUL, M.D.,
Late Member of the General Medical Council.

My chief reason for bringing forward this proposal in 1903 was that I failed to see any other plan by which we could prevent the present large total of mental degenerates from handing on their degeneracy to their offspring. According to the English Lunacy Commissioners' Report, there were, on January 1st, 1905, 119,829 officially certified insane, or 1 in every 285 of the population was insane. In 1896, 1 in 319 was insane. On the same day, there were in Scotland 17,241 certified insane, and in Ireland 22,966. In Ireland there was 1 insane person to 178 of the population; in 1851, 1 in 657. During the last fifty years the Irish population *decreased* by 31·9 per cent., while the insane rate increased by 198 per cent. A study of the statistics presented by the 1901 census of the United Kingdom shows that there were 484,507 mental degenerates, or 1 in 85 of the population. I think a more accurate proportion would be 1 in 50.

The studies of Down, Beach, Tuke, Shuttleworth, Barr, and others show that there is a deeper depth than that of ordinary lunacy. They have called attention—not to the idiot, imbecile and lunatic, but to the "feeble minded," "mentally backward," and "defective" child. It is calculated that in England at least 1 per 1,000 of the population between the ages of 5 and 14 is feeble-minded, that is 88,346. Others have placed the total at 105,000, of whom only one-third could be made self-supporting.

I would ask you to emphasise the fact that these "defective" persons are the most dangerous citizens, and especially from the procreation standpoint. Who of us would, however, wish to be joined in marriage to such a defective, or to see our children marry? This is the test. These, and the many "borderland" cases—and amongst these I would include the markedly neurotic—drive one to the conclusion that we are compelled to adopt my proposal of sterilization. One cannot drive home with too much energy the fact that there is a wide difference between the medical and legal views as to what constitutes degeneracy. No doubt, those who are not *legally* insane, but in whom insanity is latent and only requires some shock or stimulant to bring it to the surface, do beget degenerate children. But the legal mind ignores this fact, and fails to recognise that national sanity and national well-being are of more importance than is the "liberty of the subject," when considered with the question of procreation by insane persons. With the lawyer "liberty of the subject" is here synonymous with liberty to breed lunatics and to curse the offspring with indelible blemishes.

That insanity is on the increase few honest thinkers will question. The English Lunacy Commissioners, in their Annual Report, say "No sustained advance has taken place in the average recovery rate in the last thirty years." Dr. F. J. Smith says "Anatomical research and neurological inferences tend to show that recovery from lunacy is not, and cannot be, complete." The English Commissioners, in their Report, state that the number of insane under their supervision has for some time past been steadily increasing at a greater rate than the growth of the population. Thus, the rate of increase of the population during 1891 to 1901 was 12·2 per cent., while the insane community, known to the Commissioners, increased by 24·4 per cent. The Scottish Commissioners report that since 1858 the number of insane under their care has increased by 190 per cent., and the population by only 52 per cent.

I do not propose to remove the testes, or ovaries, and I object to the terms "mutilation," "castration," and "asexualization," as I do not propose to destroy either the primary or the secondary sexual characters of either male or female, even when these are insane or mutilated by the gross errors of their progenitors. In the female I propose that part of the fallopian tubes be excised and ligatured—a simple operation. In the male degenerate I have proposed two operations. In one of these part of the vasa deferentia shall be excised and ligatured (vasectomy); in the other, a portion of the spermatic chords should be excised and ligatured (spermectomy). My reasons for so proposing are: Experiments upon animals have shown that when the vasa deferentia have been divided and ligatured, the testes do not atrophy, and there is sexual power, but no power to impregnate. This in the little operation which should be undertaken is what I term voluntary sterilization. In the other operation—spermectomy—the testes do wither, and there is no sexual desire, no sexual power, and no power to impregnate. This operation would come under any division of compulsory sterilization, and would apply

*Abstract of paper read before the section of Psychology at the Annual Meeting of the British Medical Association, at Toronto, August, 1906.

to lunatics, epileptics, idiots, confirmed criminals, and inebriates, habitual vagrants, and those mentioned in Table F. Either operation should be undertaken at as early an age as is possible.

No surgeon should be allowed to operate without the written permission of the Lunacy Commissioners, not should any surgeons operate unless specially licensed by the Commissioners. A full annual report should be laid before Parliament. If any person operate without special authority and without the written consent of patient's parents or guardian, or if any person use a sterilized person for unlawful purpose, or if any sterilized person marry or join in marriage any sterilized person to any non-sterilized person without first notifying the fact to the latter, then a penalty of 15 years' penal servitude should be imposed for each offence. At present, in England *all* surgical operations are legally an "assault," and so consent must usually be obtained.

I would here call attention to the experiments of Albers-Schonberg, which show that the action of the X-rays so alter the texture of the testes of rabbits and guinea-pigs that, although these animals have sexual desire and sexual power, they have no power to impregnate. Such action would do away with the necessity of a surgical operation.

Dr. F. J. Smith partly supports my proposal. He suggests that where a woman becomes insane after confinement and kills her child she should be sterilized. But why wait until she kills her child? Also, that when insanity is due to alcohol or drugs, and the *habitue* commits a murder, such person should be sterilized. But, again, I ask, why wait until a sane person has been murdered, or until the degenerate has, perhaps, impregnated several other females? Dr. Barnardo—one who fully understood the degenerate side of life—wrote to me as follows: "Some step will have to be taken in the near future if we are to protect the nation from large additions of the most enfeebled, vicious, and degenerate type." He advocated enforced segregation, and sterilization for the few. Mr. Wells has said: "It is in the sterilization of failures and not in the selection of successes for breeding, that the possibility of improvement of the human stock lies." Dr. Lydson, in his work, "Diseases of Society," strongly supports "asexualisation." Dr. Barr, in his book, "Mental Defectives," gives strong support. In 1905 the Legislature of the State of Pennsylvania adopted a Bill legalising sterilization, but, unfortunately, the Governor refused to signet. Dr. Craddock, Medical Superintendent of the County of Gloucester Asylum (England), in his last Annual Report, says: "The sooner this day arrives (for legalising sterilization), the better for the welfare of the nation." It is encouraging further to state that many of those who gave evidence before the Royal Commission on the Feeble-minded—now sitting in London, and to which I presented evidence—have supported this proposal to sterilize degenerates. Correspondence from Canada, America and Australia show me that many—who did not wish to take a place in the fighting line—are in favour of a well-guarded system of sterilization. In an old country like England the pioneer thinker runs the grave risk of being denounced as a "crank," or a "disturber of the minds of the people." It is for this reason I have taken the opportunity of laying my proposal before the receptive minds of Canada and America. When I say that no less than ten—apparently respectable—firms refused to publish my monograph on the "Proposed Sterilization of Certain Degenerates," and severely lectured me for my audacity you can understand in a small degree the risks run by advanced thinkers.

WHAT ARE THE ALTERNATIVES TO STERILIZATION?

The *first* is the usual one of *laissez faire*—leave things alone to right themselves: a degenerate proposal—the product of degenerate minds.

The *second* is the murder of degenerates. This is another degenerate proposal.

The *third* alternative is, the supplying of degenerates with the means to prevent conception. Is it likely that lunatics, idiots, epileptics, confirmed criminals, habitual inebriates, and footpads would use such methods?

The *fourth* alternative is life-long incarceration. Such a plan would not effect a real cure, as, judging from existing conditions, many would be discharged as "cured" who were not cured. The Lunacy Commissioners always seem anxious to release the insane at the earliest possible moment. Their statistics relating to those who "recover" are a public laughing stock, and constitute a grave public scandal. Further, few physicians, in putting forward life-long incarceration, seem to have studied the taxpayer. Table C shows that in one year only over £18,000,000 were expended in the upkeep of degenerates in the United Kingdom, and, if *all* degenerates were immured, I have calculated that at least £50,000,000 annually would be required. Such a sum would cause a public revolt of the already over-burdened taxpayers.

The *fifth* alternative to sterilization is the *encouraging of suicide*. The number of suicides and of attempts at suicide are, fortunately, on the increase, and further, the attempted suicide is showing a greater tendency to murder his children before ending his or her own life. About 25 per cent. of those admitted into asylums in England have a strong suicidal desire. In the United Kingdom during 1902 there were 3,829 suicides. If this number has occurred during the last twenty years this would give a total of 76,580. But the statistics are grossly misleading, as they do not include attempted suicide, or the 6,205 who died from "drowning," (?) poison," (?) "suffocation," (?) and "not certified" by physician or coroner. I would estimate the number of suicides in the United Kingdom at 13,000 yearly. The total number, however, will never be known until we have compulsory notification to the Lunacy Commissioners of all suicides and attempted suicide. An increase of suicide cannot however, be looked to as a means of eradicating degenerates; for if to-day every insane person suicided, and we refused to attack the causes of degeneracy, there would still be as great a number of degenerates as now existing.

The *sixth* alternative to sterilization is forced abortion Criminal abortion is now very prevalent among Christian communities, and it would be dangerous to extend its scope. I regret to find that Clouston, in his work "Mental Diseases," recommends that abortion be resorted to when marked insanity comes on during pregnancy. My proposal is to kill neither the mothers nor the infants, but to make it impossible for the woman to conceive. I ask, which is the more humane proposal?

The *seventh* alternative is, making it illegal for anyone to marry until they produce a certificate of good mental and physical health. Although I have put forward this proposal as necessary, it would not meet the present conditions unless it were associated with sterilisation. We must recollect that a great many infants are begotten and born out of wedlock. During the years 1891 to 1902, no less than 425,958 children were registered in England as illegitimate births.

The *eighth*, and last, alternative to sterilisation is the plan adopted by some American States, where it is illegal for certain degenerates to marry or to be joined in marriage by a cleric or registrar. I have tried to find out if any convictions have taken place under these laws, and have failed to find any record. How could we? Is not the insane person free of punishment for his or her actions? The law of non-responsibility comes in and applies to lunatics, idiots, imbeciles, feeble-minded, in fact, to all likely to beget degenerate offsprings, and if we refuse such persons marriage they will live in concubinage or prostitution.

It is, no doubt, an appalling and humiliating fact, as shown by the 1901 Census returns that, on one day in the United Kingdom, there were 60,721 idiots, imbeciles, and feeble-minded, and of the number 18,900 were married or widowed. Here we have—

under clerical blessing—a veritable manufactory for degenerates. The same Census also shows that of 117,274 lunatics, 46,800 were married or widowed.

We must recollect that it is not only the *married* degenerates who beget. Dr. Craddock has referred to the disgusting case where a half-idiot left the asylum to be married, and who gave birth to nine idiot children in a few years. Mr. Bagnall, Local Government Board Inspector, has called attention to a woeful state of affairs where, in Yorkshire, five unmarried and feeble-minded females had been confined of no less than fifteen children.

To what goal will a policy of inaction and drift lead us? The legacy of degeneracy which has been handed down to us, and which we are wilfully preparing for the next generation, is too vast, too deep, and too far-reaching to be met by mere platitudes and mere palliations. If we adopt the cowardly idea that the existing conditions are beyond our control, and that all that can be done has been done, we recognise that anyone who brings forward a new proposal deserves an attentive and honest hearing. Fortunately, surgery comes to our aid. At present the *diseased* ovaries, tubes, uteri, and testes are removed when these organs are diseased. Last year over 2,000 women were so sterilized in the hospitals of the United Kingdom. No one objects. Next, surgery has taken a second step forward by removing *healthy* ovaries because some neighbouring organ is diseased, because of deformed pelvis, cæsarian section, ovarian hernia, mollities ossium, and enlarged prostate. Here again no one objects. I now ask that surgery take a third and chief step forward, and that, as we agree to operate for physical diseases, we shall agree to perform a trivial operation which will tend to greatly lessen and prevent mental degeneracy. Breeding from degenerates must fail. It is Carlyle who cheers all pioneers of thought by saying, "The strong thing is the just thing."

For the above and many other reasons I would earnestly ask all sociologists, and all those engaged in the care and prevention of mental degeneracy, to give a patient consideration to the proposal now laid before you.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Tumour of Testicle.—Amongst Mr. Cunning's out-patients was a boy, æt. 16, who complained of a swelling in the scrotum, which had been coming on for six months. He had taken no notice of it until a week ago, when he received a knock on the part, since when it had been slightly painful. On examination, the scrotum appeared the size and shape of a turkey's egg; the swelling was solid, hard, and painless, and seemed to be confined to the epididymis; there was no involvement of the skin nor was there any thickening of the vas deferens. *Per rectum*, no thickening of the vesiculæ seminales could be felt. With regard to the diagnosis of this case, Mr. Cunning pointed out that with reference to solid tumours of the scrotum, tuberculous disease, gumma, and new growth had to be thought of. To take syphilis first, the present tumour was one of the epididymis, whereas syphilis almost invariably affects the testis, and as there was complete absence of any other signs of syphilis the question of gumma might be left out of account in this case. Next, as to tuberculous disease: although it always affects the epididymis first, yet in a tuberculous tumour of this size the surgeon would expect to find signs which were absent in this case, namely, involvement of the skin, thickening of the vas deferens, and perhaps of the vesiculæ seminales; therefore tuberculous disease might be excluded. He was therefore left with the diagnosis of new growth. Of new growths of the testicle, there were, he said, two common ones, fibro-cystic disease and sarcoma, the former being an innocent tumour and the latter, of course, malignant. It was, he pointed out, very difficult to decide which of the two existed in this boy; he was, however, rather inclined to think the growth was sarcomatous, because it was uniformly solid, whereas in fibro-cystic disease one would expect to find soft spots. The age, however, of the boy was rather in favour of an innocent growth, although one knows how very unreliable was a question of age in the diagnosis of malignant disease. One other point was the absence of thickening of the vas deferens, which, of course, meant that it was an innocent growth or possibly an early malignant one. It was well known, too, he remarked, that the glands are involved quite early in malignant growth of the testicle, and their absence in this case was a point in the patient's favour. All points considered, he was inclined to regard it as a case of sarcoma. The treatment, whether the disease were fibro-cystic or sarcomatous, would be removal of the affected testicle.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Perinæal Wound of the Bladder.—Mr. Willmott Evans operated on a young man, æt. 18, who had been wounded in the perinæum. The patient gave a history that he had been carrying a sack containing many pieces and splinters of wood, when he suddenly fell into a sitting position on the sack, and it was found that he had received a wound in the perinæum, a splinter of wood having passed through his clothes and inflicted the wound. At first he merely felt a little pain, but towards the evening of the same day, as the discomfort increased, he came to the hospital and was admitted. On admission, a small wound was discovered to the left and a little behind the anus, into which a probe was found to enter about an inch and a half. Simple dressing was applied, and he was kept in bed. The next day it was seen that he had partial incontinence of fæces, and this symptom continued to increase for two or three days. On the second day, after admission, a little blood-stained fluid, which was apparently urine, escaped from the perinæal wound, and the temperature reached 102. Mr. Evans then saw the case for the first time, and decided on immediate operation. The patient, having been anæsthetised, was placed in the lithotomy position, and the wound in the perinæum enlarged with a scalpel; it was then seen that the deeper portion of the original wound was more extensive than had been at first recognised. A probe was now found to pass upwards and forwards for about five inches, and urine escaped. A catheter was introduced per urethram, a rubber drainage tube passed through the perinæal wound into the bladder, and several quarts of hot boracic solution were sent through the bladder by way of the catheter and out through the drainage tube. The catheter was then removed, but the tube left in position, being secured by a stitch to the edge of the wound. The patient was then returned to bed. Mr. Evans said it was clear that the splinter of wood had passed up by the side of the rectum and perforated the posterior wall of the bladder, probably through the trigonum. Possibly, he thought, the mucous membrane of the bladder had only been partly perforated for no urine had escaped through the wound for the first forty-eight hours, then the remaining thickness of the mucous membrane had sloughed or otherwise given way, so the urine escaped through the opening. The rise of temperature showed, he considered, that some septic absorption had occurred, but in all probability this would cease now the drainage was complete and thorough. The incontinence of fæces, he pointed out, was not due to any perforation of the rectum, but it

might possibly be explained by a tear of some of the outer muscular fibres of the bowel. The chief object of the operation, he remarked, was to prevent extravasation of urine into the pelvis, whether above or below the recto-vesical fascia. The former was much the more dangerous of the two, but even the latter might lead to much fever and cellulitis.

With regard to the further progress of the case: the temperature fell to normal within thirty-six hours; for a day or two most of the urine escaped through the drainage tube, but after that a gradually increasing quantity came through the urethra. Twice a day a quantity of hot boracic solution was passed through the urethra and out by the drainage tube; the latter was shortened by one inch on the third day, and on the fifth day the urine was discharged wholly by the urethra. The drain was then removed. A day or two later some urine, however, was again discharged by the perinæal wound, but this soon diminished. Within a few days of the operation the incontinence of fæces began to lessen in extent, and by the end of the first week it had almost ceased.

KING'S COLLEGE HOSPITAL.

DETECTION OF STONE IN THE BLADDER.—SUPRA-PUBIC CYSTOTOMY. REMOVAL OF TWO CALCULI AND OF ENLARGED PROSTATE.—MR. BOYCE BARROW operated on a man, æt. 76, who had been admitted with very frequent and painful micturition. Mr. Barrow pointed out that this case was of interest on account of the difficulty in detecting the calculi in the bladder. He had failed to discover the stones with the ordinary sound and the X-rays did not show them; even examination under an anæsthetic with an ordinary sound did not demonstrate the presence of a stone. Mr. Barrow therefore decided to try the evacuator, the powerful suction of which drew a stone against the instrument and a distinct click could be heard. Supra-pubic cystotomy was then performed forthwith. No difficulty was experienced in opening the bladder and two stones were found lying imbedded in a pouch hidden by an enlarged prostate. These were removed, and the patient's condition being pronounced satisfactory by the anæsthetist, Mr. Barrow decided to proceed to remove the prostate then and there. The prostate was very large, but its removal was rapidly effected; the bleeding was treated by two or three plugs saturated with adrenaline being introduced allowed to remain *in situ* for a few minutes, and then replaced by others. These were then taken away and the whole of the bladder washed out with boracic acid; a rubber catheter was introduced by the urethra, and tied in; a rubber tube was fixed in the supra-pubic opening. Mr. Barrow remarked that he had seen many instances of the value of the evacuator in discovering stones. The idea, he said, had first occurred to him many years ago, that inasmuch as the evacuator was so useful to show that a small fragment of stone remained in the bladder after lithotrity, it must be a very reliable means of finding a calculus at any time, this applying more especially to the discovery of a small stone. In an ordinary way, Mr. Barrow said, he would not advocate the removal of the prostate at the same time as the stones in the bladder of a man of this age, but, although the anæsthetic had been administered first for the examination of the bladder, and detection of the stones by the sound and evacuator, and had been prolonged for the supra-pubic cystotomy, the patient's condition appeared so good notwithstanding this extended administration that in this case Mr. Barrow felt justified in proceeding to the prostatic operation, and, the condition of the bladder being sufficiently satisfactory, there was, he thought, a better prospect for the patient after the removal of this formidable obstruction to the urine. Anæsthesia, he pointed out, had been continued for an hour and a half, yet the patient was taken from the theatre in quite a satisfactory state, and that he attributed to the discretion exercised by the anæsthetist in only keeping the man very lightly under the influence of the anæsthetic except at the more important and painful stages of the operation. Therefore, he said, an anæsthetic might be administered quite safely for a very long time providing full anæthesia was only produced at the essential periods. That showed, he considered, the value of an anæsthetist who appreciated the importance of the stages of an operation and administered the anæsthetic accordingly, and this, he said, had been admirably carried out by Dr. Flux.

It is satisfactory to state that the patient left the hospital four weeks after the operation and three months later presented himself to report his highly gratifying condition, the urine being perfectly clear, there being no increased frequency of micturition and his control over his bladder being perfect.

A SURE SIGN OF DEATH.

THE fear of being buried alive haunts very many persons, and it cannot be wondered at, as more than once cases of premature burials have come to light, while numerous are those where the supposed dead person "came to life" in the coffin just before being carried out. It is not surprising consequently that medical men have made for many years a study of the important question of complete suspension of organic life. How often have medical attendants been appealed to by the relatives or friends of the diseased in cases of sudden death as to the reality of the misfortune fallen upon them, and it requires all the tact possible of the doctor to raise all doubt on the fact.

In countries like England, where the body is kept for several days, premature burial is almost impossible; but in France and other southern countries, where the burial takes place as a rule on the third day, if not on the second, such a deplorable error is unfortunately possible. To find a sure and infallible sign of death was not easy. Some time ago someone affirmed that the burn sign was about as near it as was possible. Place a lighted candle or match beneath the fore-arm of the dead person and sufficiently near as to produce a burn of the second degree.

If the man had still a spark of life in him, the skin would raise like a blister, or, rather, like an ordinary burn, and fill with serosity in a few minutes. If, on the other hand, the man was dead, no blister would take place immediately, but later on the part would swell under the influence of gases, and burst with a crackling noise. The absence of serosity was consequently considered as a sure sign of death. The experiment was tried, and pages of medical journals were filled with different views on the efficiency of it, and finally its infallibility was rejected.

Naturally putrefaction is an authentic sign, but it is frequently inconvenient, if not dangerous, to wait for it.

Dr. Icard, of Marseilles, has come forward with a sign as sure as putrefaction itself. He found it in the sulphurous gases which precede the external signs of putrefaction, and if his experiments are found in all cases correct, he will have conferred a great benefit on humanity. He argues that sulphurous gases are found in great abundance in the lungs after death, and escape through the nose. It suffices, consequently, to have

positive proof of the reality of death, to introduce into one of the nasal fossæ, or to place under the nose, a small piece of paper (ordinary writing paper) upon which is scribbled something or anything, with a solution of acetate of lead. The writing is naturally invisible, but when brought into contact with the sulphur gases it becomes sufficiently black to be read by all, whereas at the moment of being applied, the paper was absolutely white.

It is the dead man himself who says, "I am dead," and he furnishes the proof of the truth he affirms.

The hydrosulphurous reaction takes place in all cases of absolute death and never in case of apparent death; it furnishes consequently an infallible sign, as certain as putrefaction itself, and this sign can be obtained by anyone.

The reaction shows itself generally at the end of twelve hours, but sometimes it may be delayed to twenty-four hours; in any case, it precedes considerably the dangerous state of putrefaction.

Treatment of Hæmatemesis.

Frequently gastric hæmorrhage is so abundant that the classical absolute diet is not sufficient. Injections of ergotine produce but temporary effect, while absorbent powders possess only a neutralising action. Ice to the epigastrium and ice taken is good practice, but Dr. Œttinger, of the Broussais Hospital, affirms to have had more success from a preparation of gelatine, given by the mouth, than from adrenaline or chloride of calcium.

Gelatine	1 ounce.
Sugar	1 ounce.
Syrup of lemons	1 ounce.
Water	6 ounces.

This jelly has an agreeable taste, and is taken by teaspoonsful.

Besides this treatment, he gives two or three injections of serum during the day (six ounces each time), and ice.

GERMANY.

Berlin, Sept. 16th, 1906.

The Pathogenesis of Multiple Abscesses in Infancy.

This subject has been recently discussed in a paper by Dr. Lewandowsky, in the *Arch. f. Dermat. u. Syph.* 80–2. These so-called multiple abscesses differ from the furuncular of the adult in that there is less tension and in the absence of inflammatory symptoms and by their tendency to free suppuration without any necrotic core. Escherich by developing by cultivation both the staphylococcus pyogenes albus and aureus out of them had shown that their ætiology was that of ordinary furuncular. From his own investigations Lougard has declared a hæmatogenous origin of these improbable, the histology pointing more to an internal origin than an infection from without. Internal diseases that lead to atrophy and cachexia lead to a special disposition for them. One of the chief ports of entry to the excitors of the disease are the openings of the sweat glands, a view that has been combated by Unna, according to whose observations the deep abscesses of infants as well as the boils of adults are caused by the entrance of staphylococci by the route of the hair follicles, between the hair and the external root-sheath.

The author lately had the opportunity of examining the bodies of three extremely atrophic infants with multiple abscesses. In all three cases along with the abscesses, there were in greater or less numbers small pustules with white contents and surrounded by a red margin. In size they varied from that of a pin-point to a linseed. The staphylococcus pyogenes aureus was present in both pustules and abscesses. Histological examination showed that the origin of the disease from within, *i.e.*, through transport of the staphylococci into the skin through the blood, could be excluded. It further showed that the excretion of disease found its way principally through openings of the sweat glands; he was able to follow the invasion in almost all its stages. First of all the parasites collected in the terminal portion of the exit passages, so as to completely block them up. An inflammatory reaction was not a constant sequence of this, but frequently there was intra-epithelial suppuration around the sweat glands which could be distinguished from folliculitis of the hair follicles as periporitis. It appeared clinically in the form of the above-named pustules, that stood in the same relation to the sweat-glands as impetigo Bockhart to the hair follicles. They are distinguished from these microscopically by the lesser vaulting of the pustules, the absence of central hairs, and the whiter appearance from the vesicles of impetigo contagiosa or vulgaris in that their contents are never purely serous and that they show no tendency to the characteristic formation of scabs. Periporitis plays in the pathogenesis of the abscesses of infants the same role that folliculitis impetigo does in the causation of the furuncular of adults. As, however, on the one hand numerous pustules dry up without an abscess coming forward, so on the other hand abscesses may form without a preliminary pustulation when the staphylococci penetrate into the depths of the sweat passages without causing changes of the surface. Why the mode of invasion on the infant skin is different from what it is in the adult cannot at present be explained.

Therapeutically the knowledge of this mode of invasion should lead to attempts to disinfect the skin and also by causing sweating to free the organism from staphylococci so long as the condition of the child leads to the expectation of fresh outbreaks.

Bier's Cupping Glasses in the Treatment of Tuberculous Fistulæ.

The *Zentralbl. f. Chu.* 28, 1906, has a paper on this subject by Dr. Gangele. For some time past the author has treated all cases of tuberculous fistulæ of joints that had already undergone the usual general treatment by means of india-rubber bandages and cupping glasses. In old fistulæ that had already existed for years, in which a single track the size of a knitting needle led to the disease centre, he observed a clearing up of the fistula, but never a complete closure of it. In more recent cases the track closed up quickly from within. He obtained specially good results, in the case of a weakly boy, æt. 6, who had three fistulæ from tuberculous hip joint disease. He placed the glasses on each fistulous opening twice a day for threequarters of an hour each time; intervals of three-minute suction alternating with five-minute pauses. If any secretion formed under the tender new skin forming, a small opening was made and sucked carefully; in this way perfect recovery rapidly took place.

At the Psychiatrischer Verein, Hr. Hubner showed cases of

Syphilis-Tabes Paralysis.

A patient with absence of knee jerk and rigidity of pupil had for a year found herself in a state of the greatest excitement when she got bilateral paralysis of the radial and peroneus nerves. The former got better quickly, but the latter continued to her death. There was diminution of electrical excitability and slow twitchings. She got six series of attacks, succumbing in the course of the last one. *Post-mortem*: There were found chronic meningo-cephalitis, atrophy of the frontal region, grey degeneration of the posterior columns, degeneration of the peronei, and in the region supplied by the radial nerve.

The second case was that of a woman with reflex rigidity of pupil, girdle sensation, absence of knee jerk, lightening pains and gastric crises. Anatomically along with pronounced tabes there was a gumma in the right middle fossa.

The third case was a man æt. 49, who had typical paralysis and died after three months in hospital, succumbing to the first attack. The left cerebral pia mater was strongly adherent, the attacked portion of brain having numerous blood vessels. There was a similar spot at the part where the lateral and occipital lobes joined and on the right and on the lateral lobe itself. Its gummatous character was proved. Further

there was degeneration of the lateral column in the lumbar region. It still remains to be determined whether the spirochæte pallida was present.

AUSTRIA.

Vienna, Sept. 16th, 1906.

PATHOGENESIS OF TUBERCLE.

WELEMINSKY raised the question of Tuberculosis at the Prague "Verein," in its supposed form of intection. This is always a fruitful subject for discussion, and will remain so as long as the mode of transmission continues in the present hypothetical condition. There are some, like Teppich, who affirm that tubercle is conveyed to the victim by inhalation, which Weleminsky and Cornets assert is nothing more than a dogma founded on very flimsy conclusions. Ribbert, Hausemann, etc., firmly believe in a hœmogenic infection, while Ravenuls who operated on cattle, Ohnas who experimented on apes,and Jensens on swine, all assure us that it is through the bowel that the infection of tubercle reaches the lung and other organs of the body. We have now come to regard all these channels as possible adits for the poison reaching the system, but when we hear all other ports closed but the bowel we begin to wonder how much we know of the poison at all.

Weleminsky has been experimenting with guinea-pigs since 1900 and has come to the same conclusion as Behring, that human tuberculosis is derived from the bowel, particularly in the food during infancy. He has recently altered his method of experimenting to convince himself of a recent hypothesis that the poison passes by the submental, cervical or bronchial glands to the system and not by the bowel through the mesenteric glands.

He injected tubercle below the chin of the guinea-pig, which in nine days caused the submental glands to swell; in twenty days they became caseous while the cervical and bronchial were also affected, swollen and painful. In the course of thirty-four days the cervical became caseous the bronchial much swollen, and the lung exhibited fine tubercle disseminated throughout its structure.

By subcutaneous injections into the groin the glands enlarged, became painful, and caseous and finally broke down and formed an ulcer. The infection did not stop here, but passed along the lymph channels to the iliac lumbar, and bronchial glands. These enlargements soon caused a congestion in the lymph current affecting the cervical, submental, mediastinal and axilliary glands. From the lumbar glands the mesentery became affected and from the iliac the inguinal, never the centrifugal from the centripetal, till the bronchial glands are reached, which may be considered the centre of the lymph system and to which tubercle flows from every quarter of the body. Thus the tubercle of the lung or infection is derived from the bronchial glands and carried by the blood-vessels to the pleura, forming what we have been pleased to designate "subpleural tubercle," and not transmitted along the bronchi in the lymphatic vessels as met with in infants. Weleminsky has confirmed this method of infection by many experiments, exceeding a thousand.

The question next arises: Can the bronchial glands be infected through any other channel than the lymph passages? To this he answers, No. All his experiments negative any other path of access. When both bronchial glands and lungs are found diseased, tubercle has first attacked the bronchial glands; or, generally stated, the organ never infects the lymph channels and glands but the glands always infect the organ through the lymphatics. His examinations of *post-mortems* in the human subject confirm his opinion formed by his experiments that infection by inhalation is not at all a common mode of transmitting tubercle. When the submental or cervical glands are not enlarged or diseased in the human subject, it is because they have healed, as tuberculosis is of much shorter duration in the guinea pig than in the human subject. To test this glandular infection Weleminsky used the bacillary fluid in the form of a spray, which first exhibited the specific sympto m in the submental and cervical glands, and finally the bronchial, in the same order and with the same intensity as when the animals were fed with the infect ing fluid. No germs or tubercular symptoms could be detected in the lung substance itself, though present in the glands, clearly proving its primary action on the lymphatic system and also that it is taken in from the alimentary canal and not from the lung to the glands. A piece of lung was taken from one o fthese animals which had been sprayed for half an hour, producing the usual enlargement and caseation of the lymphatics of the neck and bronchi, and placed under the skin of a healthy animal, with negative results, clearly proving the absence of tubercle in the lung substance. The narrowness of the air passages in the guinea-pig may be objected to as forming a difference of results, but it may be safely assumed from the above that the poison is more readily taken in by the alimentary canal than the lung. When inhaled and not "aspired" the germ is taken into the air passage, but expelled in the sputum to be partly swallowed and presented to the alimentary canal to be absorbed into the system. Aspiration and inspiration differ in so much as the former may be taken into the trachea direct by some abrasion, and directly affect the bronchial gland, while simple inhalation admits of complete expulsion in the sputum and a transfer to the alimentary canal.

Anthracosis of the lung in the case of miners is often advanced as proof of the deposit of germs in the lung, but the angular nature of the dust causes this to locate itself, which cannot be urged in the case of bacteria.

The tonsils have with a good deal of reason been assigned the portal through which the bacilli pass into the lymph channels, thence to the pleura and finally to the apex of the lung, which is less active and where the blood moves sluggishly to favour the growth and spread of the bacilli.

The practical result of Weleminsky's lecture was the prophylactic advice that all should breathe through the nose, where the bacteria would be entrapped and prevented from reaching the alimentary canal; and secondly, that gymnastics should be largely practised to hasten the circulation in the apex of the lung, and thus resist the danger of lung infection after the lymphatic glands have become affected.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

THE CORPORATION AND SANITARY AFFAIRS.—The past week has been a sad one for friends of municipal, and especially of sanitary reform in Belfast, and the members of the Corporation stand disgraced before all educated and honest men. The new City Hall, built and furnished at a cost which will not fall much short of half a million, was occupied for the first time on Monday, and on the same day the Corporation refused to accept the suggestion of the public Health Committee that a salary of £800 a year be offered for a competent man as medical officer of health, and at a subsequent meeting they fixed the salary at £600. This might seem to be a wise economy, if it were not well known that it is simply a step towards a flagrant piece of jobbery, which has been protested against in vain by the Ulster Medical Society, the Citizens' Association, and the best section of the Press. Though the Public Health Committee finally resolved on a salary of £800, they "swithered" about it for a long time, and are not entitled to much credit in the matter. If they had chosen to say that the health of the city was in a bad way, that a sanitary expert, trained in modern methods was absolutely necessary, and that if such was not appointed they would resign at once the Corporation could not have withstood them for a week. As it is, their action is open to at least a sus-

picion of being designed as a graceful concession to the wishes of the educated classes of the city, while they knew that their colleagues on the Corporation would not allow their zeal for reform to have any practical outcome.

Meantime an epidemic of typhoid has appeared in the Malone district, one of the best residential parts of the city. Fourteen cases have been notified, and there are said to be as many not notified. In at least eleven of the cases the milk supplied to the families comes from the same dairy, so that a strong suspicion must attach to it as the cause of the disease.

LETTERS TO THE EDITOR.

THE FALLING BIRTH-RATE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—This subject formed the chief theme of Sir J. Crichton Browne's address before the Sanitary Inspectors' Association on Thursday last. It cannot be said that the address, admirable and powerful as it was, brought forward any new facts; but it gave all the facts in argumentative order, and it ought to do something at least to stimulate the interest of thoughtful men—of thoughtful statesmen—in this tremendously important question. Sir Crichton Browne very wisely laid great stress upon the statistics lately prepared by Mr. David Heron. These statistics prove that the declining birth-rate is most evident among the classes having real claim to the designation "well-bred," whilst the physically, morally, and socially lower classes are reproducing themselves with the greatest rapidity. There can be no doubt the falling birth-rate is due to the wide adoption of the custom which has become practically universal in France—to the wilful and systematic prevention of child-bearing. This latter part—and, indeed, the whole question of the declining birth-rate, whether as regards its influence upon the parents and progeny, or its wider effects upon the State—has been within the last few years very fully debated in the editorial and correspondence columns of the medical Press.

It seems evident that a declining birth-rate due to the cause we have named—and especially a declining rate among the best-bred—must mean a diminishing racial resistance. The racial struggle is not yet over. The forces of evolution are as potent now as in the days of primeval man, and decaying races of the present epoch are as certain to be in time supplanted by more virile stocks as yet unaffected by the vices of civilisation which destroyed many nations of antiquity, and which are showing already their destructive effects upon some of the more advanced among the peoples of Western Europe.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

London, September 14, 1906.

THE DECLINING BIRTH-RATE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I am sorry your correspondent "Imperialist" misapprehends my letter, especially as I thoroughly understand his.

A very interesting letter in your issue of March 21st, signed "A Student of Sociology," on the "Census of the Empire," in tone, style of expression, and argument favours "Imperialist." France in that letter represents the scarecrow to frighten the British public. In an article in the *Daily Telegraph* which impressed me (August 27th, 1904), the writer states that "France at this moment is more powerful and influential in Europe than at any moment since the year of débâcle and dismemberment, when her conquerors believed that she had fallen, never to rise again."

The mistake of your correspondent, assuming it one, is to argue on his own hypotheses—that is to say, he assumes France's decadence; secondly, that it is wrought through a declining or stationary birth-rate. Neither of these premisses do I admit without wide discussion—certainly not the latter. I dispute the latter on the ground as stated in my letter—viz., a declining birth-rate would under no circumstances, excepting too remote to be worthy of consideration, cause the downfall of a civilised Power. On the other hand, it would be rather the complex causes which excited or induced this decline that should be held accountable. Let your correspondent find out what these are in the case of our own country, or any other nation with a declining birth-rate, then rectify these, when I venture to state the decline will at once cease and the tide commence to rise. For example, your correspondent may hear the sounds of the "Bitter Cry of the Middle Classes" from the columns of a lay contemporary. He may further discover that excessive competition and taxation render the condition of a large number of the so-called middle classes such as to make it impossible to support numerous progeny; hence they resort to measures to limit their number. Others defer marriage to a later date, whilst the least heroic refuse to marry at all. The state of the last is worse than that of the first, for the simple reason that the celibates in many instances incur and propagate venereal diseases. This is far more likely to induce degeneracy of race than a declining birth-rate. Your correspondent will observe that there are a certain clique of well-meaning, restless people nowadays, comfortably provided for themselves, whose idea is to feed the excessively educated working classes, provide recreation grounds, free libraries, etc., etc.—in a word, to provide everything without payment. This, although commendable, practically means "robbing Peter to pay Paul." Peter, however, represented by the middle classes, is driven to such a dilemma that he reluctantly in most cases seeks aid and refuge in suppressing the birth-rate. The majority of the middle class must either have recourse to this method, or they must necessarily be reduced to pauperism, or join the ranks of the very class whom they have been excessively taxed to attempt to raise to their own standard. I ask if anybody possessed of his senses could urge the British middle class to the doctrine of procreation under these conditions—a doctrine which, if carried out, must inevitably create decadence of a race long before the remote consequences of a declining birth-rate could set in—consequences which are purely hypothetical and imaginary, because, as I have stated, so soon as the causes which prompt individuals to prevent conception are removed or improved, so soon would affairs commence to right themselves, so that we may safely predict that the supposed consequences of a declining birth-rate, such as your correspondent anticipates, would never come to pass.

In my last letter I pointed out that the power of a small nation like our own is influenced only to a slight degree by virtue of its numbers. If otherwise, how would the recent war in the Far East have fared? A correspondent, discussing this question elsewhere, very truly remarked that what we require is "Quality, and not quantity." The British ship, if I may thus designate it, is already over-freighted with human cargo. We have to throw them overboard. This is the simple meaning of emigration, whilst immigration and the too rapid propagation of the human species unequivocally means at the same period taking more on. What could be more fatal to any nation?

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, September 7th, 1906.

"QUO VADIS?"

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—As an old reader of your much-esteemed journal, I was certainly somewhat surprised at reading the recent article by Dr. Bell Taylor, entitled "Quo Vadis?" So far as I can gather, he condemns vaccination, the isolation of infectious diseases, serum treatment, and holds various other unorthodox views. It is clear that your catholic policy admits statements of views that may be contrary to generally accepted professional views. Personally, I think it a matter of congratulation that at least one of our medical journals

is liberal enough to adopt an attitude of that kind. A free expression of views on both sides of a question is desirable, or, indeed, for that matter, often absolutely necessary, in order to arrive at the truth. All readers of the MEDICAL PRESS AND CIRCULAR must recognise that the editorial views are diametrically opposed to the unorthodoxy of Dr. Bell Taylor. I have written this note because I heard of one medical man who rashly assumed that the views of the writer of "Quo Vadis?" were approved by its mere publication. A moment's reflection shows the absurdity of any such criticism.

I am, Sir, yours truly,
AN ONLOOKER.

Stafford.

[The publication of an article, of course, does not commit the journal to approval of the statements therein. The same rule applies to a letter addressed to the correspondence columns. Were it otherwise, the conditions of editorial life would speedily become intolerable. The policy of excluding all views that are not strictly orthodox from the columns of a journal devoted to the interests of a progressive science like that of medicine is, in our opinion, questionable. At one stage Harvey's views on the circulation were unorthodox, and under such a rule would have been excluded from contemporary medical journals had any such existed. Our policy is to be found in our editorial columns, and not in original communications written by outside contributors.—ED. MEDICAL PRESS AND CIRCULAR.]

CAN THE INFECTION OF SCARLET FEVER PRODUCE PUERPERAL FEVER.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Now that the appeal in the scarlet fever case following confinement is concluded, I think it a fitting opportunity to discuss the question: "Can the infection of scarlet fever or the acute exanthemata produce puerperal fever?" I would first of all like to express my congratulation to and sympathy with our two medical brethren who have had to endure so much mental strain, and have been put to so much expense, and the hope that the expression of sympathy may take a practical form (they are both strangers to me).

I hold that it is quite illogical to teach that attendance on a case of the exanthemata not complicated by suppuration can convey septic poisoning to a parturient woman—as well might one expect a field of wheat where only grass seed had been sown—or small-pox to be caused by the infection of typhus. Erysipelas and diphtheria come under a different rule, and therefore the reason for continuing them in the list of notifiable diseases.

In years gone by I frequently attended women in their confinements in the same room, and even in the same bed, with measles and scarlet fever, and never once saw septic results. I need hardly say that I do not advocate the continuance of this practice, on account of the fear of infection to the baby. Of course, no prudent man would attend a confinement after examining suppurating glands or running ears or nose without taking the same minute precautions which he would deem necessary after making a post-mortem on a putrid body, or opening a foul abscess. After a very long and extensive experience, I hold that the exanthemata may be conveyed to the parturient woman the same as to any other person, but puerperal fever never, the only exceptions being erysipelas and diphtheria.

I am, Sir, yours truly,
JAMES HAMILTON, M.D., Q.U.I.

60, Sydney Street, Chelsea,
September 15, 1906.

OBITUARY.

THOMAS HARRIS, M.D.LOND.

WE regret to announce the death of Dr. Thomas Harris, of Manchester, which occurred somewhat suddenly at Brewood, in Staffordshire, on the 8th inst. He had a distinguished academical career. He was first in first-class honours in physiology at the first M.B. London, 1878-9. He took his M.B. degree with first-class honours in 1882, qualifying for gold medal, and his M.D. a year later. Dr. Harris was at the time of his death lecturer on diseases of the respiratory organs at the Manchester University, a position he filled for several years. Before holding that appointment he was pathologist to the Manchester Royal Infirmary and assistant to the Professor of Pathology at the University. Subsequently he became physician to the Manchester Infirmary, and physician in charge of the throat department. He was at one period on the active staff of the Consumption Hospital, and at the time of his death held the office of consulting physician. His medical writings were numerous. Perhaps his most important book was "Indurative Mediastino-Pericarditis," published in 1895. He wrote also a Post-mortem Handbook and published "Clinical Lectures on Pathology and Diagnosis of Early and Late Stages of Pulmonary Phthisis," as well as many papers in the medical journals.

JOHN HENRY BELL, M.D. ST. AND., M.R.C.S.ENG.

WE regret to announce the death of Dr. John Henry Bell, of Bradford, for many years a prominent member of the medical profession at both Leeds and at Bradford, at the age of 74. Coming of a well-known Scottish family, he was born in Bradford, the son of Mr. W. Bell formerly of Kirkcudbrightshire. In 1857 he started practice at Bradford and rapidly gained a large clientèle, and was elected on the staff of the Bradford Infirmary. He gave special attention to anthrax, and wrote on the subject in Allbutt's "System of Medicine," and other articles of the same nature, including "Anthrax in its Relation to the Wool Industry. He was president of the Bradford Medico-Chirurgical Society, a member of the Royal College of Surgeons, and a Licentiate of the Society of Apothecaries. In 1861 he took the degree of M.D. at St. Andrews.

EDWARD GAYLOR, L.R.C.P.EDIN., L.F.P.S.GLAS., D.P.T., OF BELPER.

WE regret to announce the death of Dr. Richard Gaylor, of Belper, in his seventy-sixth year. In spite of a long life spent in medical practice, he kept in harness to the last, and was attending to his duties as medical officer of health within a few days of his death. Deceased was born at Morden, in Herefordshire, received his medical education at Sheffield, whence he qualified as L.R.C.P.Edin. and L.F.P.S. Glas., in 1865. He contributed articles on various subjects to the medical journals. Dr. Gaylor was prominently engaged in the public life of Belper during the last half century, especially as regards politics. He was not less widely known than he was highly esteemed in the country.

SPECIAL ARTICLE.

THE SOURCES OF GOVERNMENT VACCINE LYMPH.

WE have been asked to publish the following correspondence which has taken place between Sir William Collins, M.D., M.P., and the President of the Local Government Board in reference to the original sources of the lymph supplied by the National Vaccine Establishment for the purposes of public vaccination:—

House of Commons,
July 8, 1906.

DEAR MR. BURNS,—

In consequence of your negative reply to my question put to you on June 28th asking for a Return showing, as far as is known, the original sources of the vaccine lymph now in use, and at your own request, I put down another question on the same subject on July 4th. The answer to this does not contain the information asked for.

I think the public have a right to know what are the

original sources of the lymph used or supplied by the National Vaccine Establishment. If the sources are not known, why not say so? If they are known, why not state them?

I know the lymph is cultivated on a series of calves, but what is the original source from which the lymph was obtained? Vaccine vesicles do not appear spontaneously either on the shaven abdomens of calves or on babies' arms.

Before the Royal Commission great importance was attached to the original sources of lymph, as, indeed, was the case with Dr. Jenner himself. We were informed that results resembling vaccine could be obtained from such varied sources as horse grease, cattle plague, small-pox, sheep-pox, syphilis, and from the inoculation of tartar emetic.

I want to know how many strains are now in use, whence they were obtained, and what investigations were made into the genuineness of the disease in the animal originally yielding the lymph.

Yours sincerely,
W. J. Collins.

The Right Hon. John Burns, M.P.
Local Government Board,
Whitehall, S.W.,
July 13th, 1906.

Dear Sir William,—

Adverting to your letter of the 8th instant, with regard to the original sources of the vaccine lymph supplied by the National Vaccine Establishment, I may say that I have answered several questions in the House on this subject, but since the receipt of your letter I have again gone into the matter very carefully.

In view of the Act of 1898, and of the adoption by the Government of glycerinated calf lymph for all public vaccinations, the Local Government Board made an entirely new departure as regards the source of vaccine lymph. Dr. Blaxall, the newly-appointed Director of the Board's Glycerinated Lymph Establishment, obtained as stock for starting his series of calf-to-calf vaccinations lymph from Cologne. This lymph which had been long in use there, and had originally been obtained, it was believed, by vaccinating calves from the arms of infants, has continued to be employed in the vaccination of calves at Lamb's Conduit Street to the present day.

Side by side, however, with this calf-to-calf lymph of Cologne pedigree, other lymph has from time to time been taken into use at the Board's establishment. This other lymph has been partly retro-vaccinated Cologne lymph—*i.e.*, lymph passed from the English infant back to the calf (after glycerination) to the infant again, and partly it has been lymph newly obtained from continental stations and passed through a series of calves before adoption for use in the Board's Establishment.

With regard to the "original" sources of lymph of the latter kind, I may remind you that in my reply to your question in the House of the 28th ultimo, I said, referring to the fact that in some instances lymph has been obtained from abroad, that "in such cases it would usually not be practicable to give its original sources," and in this connection I may also refer you to the reply which I gave to a question by Mr. J. W. Benn on March 23rd last, in which I stated that "occasionally lymph has been procured from abroad," and it is possible that in some instances of this kind the lymph may have been originally derived from artificial inoculation of calves with small-pox, but in no case is lymph used at the establishment unless it has been passed through a series of calves.

Yours truly,
John Burns.

House of Commons,
July 14th, 1906.

Dear Mr. Burns,—

I am much obliged for your communication of 13th inst., but neither in it nor in any of the replies to the many questions put to you in the House can I find any definite information as to the point on which I sought information, viz.: the *original sources* of the lymph supplied by the National Vaccine Establishment.

To say that lymph was brought from Cologne, and that it was there obtained by vaccinating calves from infants' arms, tells nothing of its original source or the nature of the disease from which the strain was originally derived.

Is it really not possible to say whether the lymph supplied by the National Vaccine Establishment was derived originally from the small-pox of man, the pox of the horse, or from an eruption on the teats of a cow, and if the latter, whether it was the true or spurious cow-pox?

Yours very truly,
W. J. Collins.

The Right Hon. John Burns, M.P.
Local Government Board,
Whitehall, S.W.,
July 24th, 1906.

Dear Sir William,—

Adverting to your further letter, I am afraid I cannot add much to what I have already said.

As to the remote ancestry of the Cologne lymph, whether it was derived from casual cowpox or induced cowpox, we do not know.

The Department were satisfied when it was adopted, that it was producing and had long been producing in calves what the German experts regarded as characteristic vaccinia, and that lymph transmitted from such calves to babies protected them against small-pox.

Yours truly,
John Burns.

Sir W. J. Collins, M.P.
House of Commons,
July 28th, 1906.

Dear Mr. Burns,—

Thanks for your further letter of 24th. I am sorry that the Local Government Board cannot vouchsafe any information as to the original sources of the lymph supplied by the National Vaccine Establishment.

As to the Cologne stock, may I ask you to be so good as to refer me to the evidence on which your department were satisfied as to its character Was it tested by the variolation or attempted variolation of those who had been vaccinated with it?

Yours truly,
W. J. Collins.

No reply has been received to this letter.

The questions referred to in the correspondence are the following:—

Thursday, June 28th, 1906.

Sir William Collins asked the President of the Local Government Board if he will grant a return showing, as far as is known, the original sources of the various stocks of lymph which have been, or are being employed by the National Vaccine Establishment, indicating those strains which are no longer in current use.

Mr. John Burns said: As I have stated in reply to previous questions, the usual method of renewing lymph supplied from the National Vaccine Establishment is by vaccinating calves with vaccine lymph obtained from children, but in some instances the lymph has been obtained from abroad, and in such cases it would usually not be practicable to give its original sources. In these circumstances I do not think that a Parliamentary Return of any value could be given. I may, however, state that in no case is lymph used at the Establishment unless it has passed through a series of calves.

Wednesday, July 4th, 1906.

Sir William Collins asked the President of the Local Government Board if he will state the original sources from which the stocks of lymph now used or supplied by the National Vaccine Establishment were derived—whether obtained in this country or from abroad—and the evidence upon which the genuineness of the vaccine derived from the animal originally yielding the same was established.

Mr. John Burns said: I think I must refer my hon. friend to my reply to the question on this subject which he put to me on the 28th June last; but I may add that no lymph which on being passed through a series of calves is productive of appearances differing in any way from those characteristic of vaccinia in the calf is issued from the National Vaccine Establishment.

MEDICAL NEWS IN BRIEF.

An Anti-Vivisectionist Monument.

A "MEMORIAL to a little brown dog" was unveiled by the Mayor of Battersea (Mr. W. Rines) in the Latchmere Recreation Ground, Battersea, on Saturday afternoon. The fountain was presented by the International Anti-Vivisection Council, and has been constructed in memory of a little brown dog whose bronze model surmounts it. On one side of the fountain is the following inscription:—"In memory of the brown terrier dog done to death in the laboratories of University College in February, 1903, after having endured vivisection extending over more than two months and having been handed over from one vivisector to another, until death came to his release." The fountain cost £130, which was raised by subscription among the members of the International Anti-Vivisection Council, who first of all applied to the London County Council for permission to erect the fountain in Battersea Park. Failing to get this permission they presented the fountain to the Borough Council. An action for libel has been threatened, and was at first derided by Battersea councillors, but on Wednesday the Council put its seal to an agreement whereby the International Anti-Vivisection Council undertook to indemnify the Corporation against all risks. Earnest money to the amount of £300 has been deposited. At the unveiling the Mayor was supported by Lady Seafield, Lady Nina Ogilvie-Grant, and the Rev. C. Noel. Mr. Jeffery, L.C.C., formally presented the fountain. The Mayor of Battersea accepted the gift on behalf of the municipality. He said the gift was accepted despite threats of all sorts of pains and penalties. In the interests of humanity the Council were prepared to take whatever consequences might come to them. Mr. West and Mr. Watts, formerly mayors of the borough, proposed and seconded a vote of thanks to the donors. The uncompleted recreation ground, which has been laid out by the unemployed, was afterwards declared open by the Mayor, who said that in the event of any threats being put in operation he hoped all present would constitute themselves custodians of the little brown dog.

Danger of Tea Drinking.

DR. WYNN WESTCOTT, at an inquest at Hackney last week, declared that to drink tea with meat was one of the most injudicious things that could be done. The inquest was held on the body of a woman music teacher, who died suddenly while giving a lesson. The evidence showed that just before the lesson began a heavy meal of beefsteak, tomatoes, and tea had been taken in a hurry. An autopsy showed that the meat was not digested, and a doctor declared that it had caused syncope. The coroner said that tea prevented the flow of the gastric juice which was necessary to digestion. "Water with meals, or beer, if one had the wickedness to drink it, was far better than tea," he said. "I am sorry," Dr. Westcott continued, "if anything I have said goes against teetotal doctrines, but if people must be teetotalers they had best drink water and not tea. Tea is all very well between meals, when it can do no harm." A verdict of "Death from natural causes" was returned.

The Cost of Pauper Lunatics.

AT the request of the Finance Committee of the London County Council, the Asylums Committee have drawn up a report upon the causes which have led to the increase in the weekly charge for the maintenance of each patient in the London County asylums from 9s. 1½d. in 1890-01 to 11s. 4½d. in the year 1904-5. From this report it appears that, whereas in 1890 the actual expenditure for the maintenance of lunatics was £174,360, this had risen in 1904 to £498,393. During the period under review the number of patients has largely increased, and several new asylums have been provided. The committee account for the increased maintenance rate by pointing out, in the first place, that all the officers and attendants have been placed under improved conditions of service and pay, while the ratio of attendants to patients in all the asylums has been largely increased. In the new asylums the wards are, in conformity with modern ideas, made considerably smaller than in the older institutions, and this in itself necessitates the employment of a larger staff. No male adult servant in the employment of the committee receives remuneration equivalent to less than 25s. a week. The increased weekly expenditure per patient of 5.23d. for provisions is accounted for by an improved and increased dietary and an improvement in the standard of the articles supplied, as well as by the higher contract prices of certain articles which now obtain. English-killed beef has been substituted for frozen beef and an addition of 2oz. per patient weekly has been made to the allowance of meat. The staff dietary has also been largely improved. Increased expenditure is also shown under the heads of necessaries (including fuel, lighting, washing, furniture, and property), surgery and dispensary and rates. Even with this increased expenditure, a comparison of the cost at London County asylums with that at the extra-metropolitan asylums is generally favourable to the London asylums. Certain economies have recently been effected in asylum administration, and the committee hope that from the present time the weekly maintenance rate per patient will work out at 11s. 1d.

The Outbreak of Typhoid at Basingstoke.

AFTER the recent outbreak of typhoid fever at Basingstoke, the cause of which was traced to the town water supply, the borough council had 50 actions for damages entered against them in the High Court, the sum claimed as damages being nearly £4,000. So serious was the outbreak that many of the victims had to be helped by a relief fund. A committee of the claimants was afterwards formed, and this committee agreed to meet a committee of the Ratepayers' Association to adjust the claims, and the result has been that the council have agreed to pay £1,670 15s. in settlement of the 50 claims brought, without prejudice and with denial of liability. Since the epidemic the town has gone to a fresh source for their water supply. —*Times.*

Milk Sold from Infected House.

A PECULIAR case, having a connection with the epidemic of typhoid fever last week on the banks of the Noran, was heard in Forfar before Sheriff Lees. Mrs. Mabel Sampson, wife of a farmer, Noranbank, was charged with having contravened the Public Health (Scotland) Act in so far that while living in an infected house, she engaged in active connection with food by supplying milk to James Robertson, Noranside. Accused pleaded guilty, and Mr. Philip appeared for the Brechin District Committee. He stated that there had been an epidemic of typhoid fever on the banks of the Noran for some time, and it was still going on. Mrs. Drummond was one of the first sufferers, four of her children being attacked. She seems to have foolishly sold a pennyworth of milk, and did it more for obligement than profit. The Brechin District Committee did not ask for a severe penalty seeing accused had suffered a great deal as the result of the epidemic. Sheriff Lee modified the sentence to a fine of 1s. and 1s. of expenses, or three days' imprisonment.

Sanitary Officials' Congress.

DELEGATES assembled last week at Blackpool for the annual Congress of Sanitary Inspectors. They were formally welcomed at the Town Hall in the afternoon by the Mayor (Mr. W. H. Broadhead). The business of the Conference opened with a presidential address by Sir James Crichton Browne. Among other interesting papers may be mentioned those of Dr. Hyslop, of Bethlehem Hospital, Southwark; Dr. Hope, Medical Officer of Liverpool; Mr. Robert Lindsay, Sanitary Inspector, Edinburgh; and Mr. James McPhail, Chief Food Inspector, Hull.

Measles in Cheshire.

AN extensive epidemic of measles is reported from Haslington, near Crewe, and that the schools have had to be closed. There are said to be also cases at nearly every house in Crewe. The attendance at school is considerably affected by the prevalence of the malady. One of the infants' schools was ordered to be closed, but this does not appear to have done much to check the spread of the disease.

Apothecaries' Hall of Ireland.

THE autumn sessional examinations will commence with the First Professional on Monday, October 15th, 1906. Entries, schedules, &c., must be lodged at least fourteen clear days beforehand, with the Registrar, 30, Mary Street, Dublin.

AN unusually virulent outbreak of diarrhœa is reported in certain villages of south-east Lancashire. Hundreds of cases have been under treatment during the past few days, and nearly a score of deaths—chiefly among children—have been notified in the above-named localities. Many factory operatives are incapacitated from work.

Indications for Operations in Diseases of the Internal Organs. By Professor Hermann Schlesinger, M.D. Translated by Keith W. Monsarrat, M.B., F.R.C.S.Edin. Pp. 498. Price 9s. 6d. net.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Enlargement of the Spleen in Rickets. — Cowan and McClure (*Brit. Journ. of Children's Diseases*, August, 1906) have undertaken an investigation to ascertain the exact relationship of enlargement of the spleen in rachitic children to the disease itself. In the middle of the seventeenth century, Glisson had drawn attention to the fact that the viscera are sometimes enlarged in this disease, but even among modern writers there appears to be little agreement as to the exact histology of this enlargement. Dickinson, writing in 1869, describes four cases giving the microscopical appearances of the affected organs and making it clear that the changes found were due, not to the presence of any formation foreign to the structures of the viscera, but to an irregularity of growth which altered the normal proportions of their tissues; the condition he thought was *sui generis*. Later writers are by no means agreed as to the proportion of cases in which enlargement of the spleen occurs or whether such enlargement, if it does occur, is to be looked on as part of the disease or a mere coincidence. Drs. Cowan and McClure have made an examination of 417 consecutive cases of rickets at the Dispensary of the Royal Hospital for Sick Children, and found the spleen "palpable" in 17, or 4.07 per cent. In only eight of these seventeen cases were they definite that the spleen was really enlarged, and in five of these eight there was considerable thoracic deformity. Trousseau had maintained that though the spleen in rickety children might often be felt below the ribs, yet it was not enlarged, but that the prominence was due to displacement as the result of thoracic deformity. Among Dr. Cowan's and Dr. McClure's cases there were only two with notable enlargement of the spleen. In one of these cases the blood revealed changes characteristic of splenic anæmia, and the patient in the second case was suffering from measles and died in the attack. The writers conclude that "it seems improbable splenic enlargement is merely an incident of rickets, when the viscus is only palpable in less than 5 per cent. of cases. In our opinion notable enlargement of the spleen in rachitic children is the result of other causes than rachitic, the most common of which are splenic anæmia and congenital syphilis."

K.

Air Dilitation in the Treatment of Chronic Constipation.—Hirschman (*Med. Record*, August 11th, 1906) discusses this method of treating chronic constipation. He has devised a simple pneumatic dilator for distending the rectum or sigmoid. This consists of a rubber bag with a stem which is slipped over the distal end of a Wales bougie (No. 3-5). Compressed air at a low pressure is allowed slowly to enter the bag, and distension to any desired extent is produced. Where the compressed air apparatus is not convenient a small bicycle pump may be utilised. The patient is placed in the Sims position. The bag is deflated, lubricated, and passed up into the rectum or through the rectum into the sigmoid to any desired height. When in position the bag is slowly inflated until the patient complains of a sense of either fulness or pain, or a desire to move the bowels. The air is then allowed to escape and after an interval of a few seconds it is again inflated to the point of tolerance. This alternate inflation and deflation is repeated four times to the minute for about five minutes. The bag is then again inflated to the point of tolerance, the opening in the bougie closed by the thumb, and by â to and fro motion the apparatus is gently and slowly withdrawn. This massages the bowel as it is withdrawn and also gently dilates the sphincter. The treatment is continued daily for about a week and then at longer intervals. Dr. Hirschman says that in an experience extending over nine months he can recall but two cases in which success was not obtained. In about 80 cases, so far as he has been able to learn, permanent good results were obtained.

K.

Extensive Ringworm.—Sequeira (*Brit. Journ. of Dermatology*, August, 1906) records two cases of extensive ringworm of the trunk occurring in patients who lived in London and who had not been in contact with people who had been in the tropics. The first case was that of a boy, æt. 14, who had been affected since he was 7 years old, and who applied for treatment for an ulcer, the size of a crown piece, about the umbilicus. Almost the entire trunk, parts of the arms, the hands, and front of the feet were found to be infected with ringworm. The finger nails were extensively infected but the toe nails had escaped, the face and scalp were also unaffected. The eruption itched a good deal and the boy was constantly scratching. There was no evidence of visceral disease, and the boy was well developed, but thin and anæmic. The second case was that of the boy's sister, æt. 21, and she had been infected with the disease since 7 years of age. In her case the distribution was not nearly so extensive, but the finger nails were infected; the face and scalp with her, like the boy, had escaped. In each case scrapings from the skin and nails showed a large quanity of mycelium and some spores. The fungus in both proved microscopically to be the common endothrix. The exudate from the ulcer in the boy's case also contained the fungus. The girl refused treatment, and the boy's parents refused to allow the nails to be removed, so that complete cure was impossible.

K.

Diagnostic Significance of Ocular Reflexes.—Kempner (*Berlin Klin. Woch*, 1906) has been studying this subject on hundreds of persons, including 350 cases of organic affections in the domain of the trigeminus, and 400 without organic trouble. After discussing the anatomy and physiology of the parts, he tabulates his findings in detail and classifies the cases. When the corneal reflex was absent or diminished, this occurred on one side only in the cases of organic affections, while it was bilateral in the functional disturbances. In the organic cases, the anomaly in the reflex was generally accompanied by sensory disturbances affecting the trigeminus or some of its branches, while in the merely functional cases there were no sensory disturbances, or if present they did not correspond to the trigeminus area. In cases of a tumour in the posterior cranial fossa the cornea was first affected, then the rest of the first division of the fifth nerve, and then the second, and finally the third division, while in the true functional cases the reflex anomaly and the sensory disturbances were not progressive and were not liable to alternate irregularly. In four cases the diagnosis wavered between tumour of the cerebellum and hydrocephalus; the corneal reflex was normal or exaggerated. Hydrocephalus was found in the two that came to autopsy.

D.

The Use of Thyroid Extract to Shorten Coagulation Time of the Blood.—Dr. Wm. Taylor (*Boston Med. and Surg. Journ.*, July 26th, 1906) advises that thyroid extract be used in cases of hæmophilia where operation was demanded or where they had received any accidental wound, and also in patients whose blood had been altered by disease. He stated that normal blood was not affected in any way by the use of thyroid extract, even where its use had produced distinct constitutional defects, that it acted only upon blood which lacked fibrin ferment. He mentioned the fact that A. E. Wright had found that the coagulation time of the blood was lengthened by starvation

and shortened immediately after a hearty meal, and the efficiency of the action of calcium chloride was increased by combining it with an albuminous substance, such as an aqueous extract of thymus, thyroid, testicle, gastric, and other mucous membranes. He cited three cases of bleeders in which thyroid extract was used with marked benefit, and mentioned one instance in which it was used in a case of profound jaundice due to obstruction of the hepatic duct. He recommended that in all cases of suspected or probably delayed coagulation time the blood should be carefully tested and the dried thyroid extract given in 3-grain doses in capsules three times a day, and stated also that it had been used with very great effect in several cases of purpura with spongy and bleeding gums, occurring during the course of typhoid fever. D.

Signs n Congenital Tendency to Tuberculosis. —Sorgo a d Suess (*Wien. Klin. Woch.*, Vienna, 1906) have found in their experience that the mamma on the side of a unilateral tuberculous process is always smaller in all respects than its mate. Among 111 tuberculous female patients examined, the areolæ were of unsymmetrical size in 52, and among these the tuberculous process was unilateral in 18. In every instance the smaller nipple and areola were on the side of the morbid process (right 12, left 6). In 19 others the process was predominant on one side, and this side was always that of the smaller areola (right 5, left 13). Similar proportions were found in 168 male tuberculous patients examined. The findings suggest an unmistakable connection between the comparative atrophy of the one breast and the predisposition to tuberculosis of the lung beneath. D.

Phlegmonous Enteritis. — MacCallum contributes an article on this rare affection to the August number of the *Johns Hopkins Hospital Bulletin*. In all, seven cases up to this have been recorded, in five of which the inflammation was limited to the upper part of the small intestine; in one the colon, and in one the whole of the digestive tract was involved. The case now reported is that of a negro, æt. 75, who was admitted to hospital suffering from abdominal pain and vomiting Three weeks previously he had met with an accident and had got a scalp wound, but had apparently completely recovered from the effects of this. The day before admission, he first suffered from the abdominal pain, which rapidly grew worse. On admission he was much collapsed, and presented symptoms and signs of intestinal obstruction. A laparotomy was performed, and the wall of the upper part of the jejunum was found thickened and brawny-looking, but without any signs of kinking or strangulation. Nothing further was done, as the patient was too weak to allow of further manipulation, and death occurred some hours later. At the necropsy the lumen of the thickened part of jejunum was found full of soft, yellowish-white material, and the valvulæ conniventes stood up as thick, opaque, rigid and swollen folds. On making an incision the submucosa was seen to be greatly thickened, and yielded a turbid fluid on pressure. Microscopically, this coat, and also the muscular coats and muscularis mucosæ were found infiltrated with cells, both lymphocytes and neutrophile leucocytes, and with fibrin, while in addition the lymphatic channels were engorged with cells, and a thin layer of fibrin was present on the peritoneal surface of the gut. The causative organism was not isolated, but from its appearance in stained sections, there was little doubt that it was the streptococcus pyogenes. It is supposed that traumatism may have some effect in causing this lesion, the upper part of the intestine being more readily injured on account of its relatively fixed position. In support of this view it is to be noted that the epithelial lining of the interior of the gut was intact in this case, and in other recorded instances. M.

The Treatment of Infantile Paralysis by Nerve-Anastomosis. — Hackenbuch (*Deutsch Med. Woch.*, 1905, No. 25) has treated three cases of paralysis of the peroneal group of muscles in children due to anterior poliomyelitis, by means of nerve anastomosis. The operation consisted of exposing in the popliteal space both tibial and peroneal nerves by an incision over three inches in length. Then he separated from the stem of the tibial nerve a flap of about one-third of the thickness of the entire nerve stem, and in such a manner that it remained in continuity with the central end of the nerve. This flap was then attached to the peroneal trunk; the wound was stitched up, a small gauze drain being inserted, and a splint was applied. After ten days the splint was removed, and a simple bandage put in its place. Healing had by this time taken place. In two of the cases no improvement took place, possibly, according to the author, owing to a keloid thickening of the scar extending in to the nerve suture. Both of these cases were in quite young children, and in both the paralysis was definitely limited. On the other hand, a splendid result was obtained in the third patient, and had first shown itself nearly two years before the date of this report. The patient was a girl, æt. 12, who had had paralysis of the left leg for ten years. A total paralysis of the peroneal group and of the extensor longus and brevis digitorum muscles was cured, and the patient is now able to use her foot normally both in standing and walking. M.

Myasthenia Gravis.—Albertini (*Bull. delle Scienze Med.*, 1906) has had the opportunity of observing two cases of this malady, one in a male, and the other in a female. In the man the first symptom was intense weariness, which during the last four years set in suddenly after any severe exertion. Later came lingering pains in the upper extremities. No great change had taken place for some time. The woman had suffered for two years from headache and vertigo. Later on appeared tremors, nausea, palpitation, cloudiness of vision, and general weakness; then a feeling of great weariness, and painful respiratory movements. The author regards the diagnosis in both cases as certain, and has been able to exclude such possibilities as traumatic neurosis and hysteria. He does not consider the absence of bulbar symptoms as of importance, as they only appear in the very late stages. Commenting on the condition, he states that it essentially consists of hypotonia, and of a persistent fatigue of the nerve centres, which control the reflex motor functions, especially those which control respiration and the vaso-motor functions. Coupled with the above there exists depression of the intellectual faculties and a rapid wearying of the nerve centres which functionate intermittently, including those that govern voluntary motion. The only cause that seems at all likely to be present is some toxin acting on the nerve-centres. Treatment consists in rest and the removal of all nerve excitants. Massage, galvanisation, and drugs are useless. M.

Vesipyrin: A New Anti-rheumatic and Urinary Disinfectant. — According to the chemical formula, vesipyrin stands in the same relation to salol, as aspirin does to salicylic acid. The conclusions that Hoffman and Luders (*Therapie der Gegenwart*, 1905, No. 2) have come to concerning it are as follows: On account of its being broken up in the intestine and entering the blood as salicylic acid, it is a true anti-rheumatic and a true urinary disinfectant. Further, it is superior to the similar and better known remedies, in that it has no tendency to cause nephritis. It does not irritate the stomach, and is well borne, because the decomposition into salicylic acid does not take place till the intestine is reached. It lends itself, moreover, to the treatment of patients who are not confined to bed, because little or no sweating is caused by its use. As special indications for its therapeutic employment, the authors mention cystitis, pyelitis, and all conditions which require disinfection of the genito-urinary tract, as well as articular rheumatism, neuralgia, and influenza. An ordinary day's dose may be from 2 to 5 grammes. It is best dispensed in the form of tablets, which render it completely tasteless. M.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READER.—You can still get W. E. Henley's little book "In Hospital" The poems form a record of his experience in the Edinburgh Infirmary in the early seventies. His work, either medical or poetical, was never impaired by his exhausting illness, tuberculous arthritis.

DR. S. (Bath).—You will get comparatively little for your books. Some could be disposed of privately, but a dealer will only give you so much a hundred. Books which have cost 35s. often go for 5s.

PREPARATION.—The "Harrington" formulæ is:—

Alcohol (94 per cent.) - - -	640 cc.
Hydrochloric Ac. - - - - -	60 cc.
Water - - - - - - - - -	300 cc.
Perchloride of Mercury - -	·8 grammes.

AU PIED DE LA LETTRE.

LITERATIM.

In Washington there is a slab
Erected unto Hahnemann,
And on it there is chiseled large
A warning unto any man.

For underneath the statue stands
This motto in the centre,
Similia similibus,
And under it, *curentur*.

And can it mean, "Who reads should run,"
In grammar homeopathic,
Remorse and good advice in words
Significantly graphic?

Or does *curentur* promise cures,
A jolly kind of banter?
Or was some conscientious soul
Afraid to write *curantur*?

—*American Medicine.*

N.B.—With acknowledgement.

PELVIS.—Bandelocque's pelvimeter has been modified by many obstetricians. You will find Martin's the most handy for all-round purposes.

FEBRIENTA.—The term, simple continued fever, should not be used if it can possibly be avoided, but it cannot be said to be inadmissible.

MIDWIFE.—Four certificates, not three, are required. One is that of good character, and the other three relate to training. Special forms are prescribed for all.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 19th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X Rays. Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. L. Daniel: Clinique. (Surgical.)

THURSDAY, SEPTEMBER 20th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Diseases of the Eye.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical).

FRIDAY, SEPTEMBER 21st.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Medical and Surgical Clinics. 2.15 p.m.: Diseases of the Throat, Nose, and Ear. 2.30 p.m.: X-Rays. Operations. Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. E. Waggett. Clinique. (Ear.)

SATURDAY, SEPTEMBER 22nd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

Vacancies.

Great Northern Central Hospital, Holloway. — Pathologist and Curator. Salary £100 per annum. Applications to L. H. Glenton Kerr, Secretary.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to Arnold J. Cleaver, Government Buildings, Liverpool.

Cardiff Union.—Assistant Medical Officer. Salary £130 per annum, with rations, apartments, attendance, and washing. Applications immediately to Arthur J. Harris, Clerk, Union Offices, Queen's Chambers, Cardiff.

Sussex County Hospital, Brighton.—House Surgeon. Salary £100 per annum, with board and residence in the hospital, with washing. Applications to the Secretary.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Manchester Education Committee.—Assistant Medical Officer. Salary £200 per annum. Applications to Charles Henry Wyatt, Director of Elementary Education, Deansgate, Manchester.

Bromyard Union.—Medical Officer required for No. 1 District.—Particulars of E. L. Cave, Solicitor, Bromyard. (See advt.)

St. Pancras and Northern Dispensary, 126 Euston Road.—Resident Medical Officer. Salary £105 per annum, with residence and attendance. Applications to the Hon. Secretary, H. Peter Bodkin, 23, Gordon Street, London.

Bedford County Hospital.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry. Applications immediately to W. F. Morley, Secretary.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Rev. Philip Lancashire, Hon. Sec., Oldham Infirmary.

North Riding Infirmary, Middlesbrough.—House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to Chas. Postgate, Secretary.

The Chorlton and Manchester Joint Asylum Committee.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to Henry Woodhouse, Clerk to the Joint Committee, Chorlton Union Offices, All Saints, Manchester.

City of Birmingham Asylum, Rubery Hill, near Birmingham.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, &c. Applications to the Medical Superintendent.

Fermanagh County Infirmary.—House Surgeon. Salary £52 per annum. Applications to Mr. C. Wilson, Secretary. (See advt.)

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Applications to W. M. Wilcox, Secretary.

Appointments.

CANN, F. J. H., M.B.Lond., Certifying Surgeon under the Factory and Workshop Act for the Dawlish District of the county of Devon.

CORNER, S. G., M.B., Ch.B.Edin., House Surgeon at the Essex and Colchester Hospital.

DODGSON, GEORGE STANLEY, M.B., B.C.Cantab., Medical Officer to the Sherburn Hospital, near Durham.

FLITCROFT, THOMAS E., L.R.C.P. and S.Edin., L.F.P.S.Glasg. Resident Medical Officer at the Warrington Union Infirmary.

JEFFREY, G. RUTHERFORD, M.B., Ch.B., Senior Assistant Physician to the Crichton Royal Institution, Dumfries.

ROBERTS R. J., L.R.C.P. and S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Corris District of the counties of Merioneth and Montgomery.

THOMAS, A. H., L.S.A., Certifying Surgeon under the Factory and Workshop Act for the West Drayton District of the county of Middlesex.

WILSON, WILLIAM CHEYNE, M.D.Edin., Honorary Physician to the Devon and Cornwall Certificated Industrial School for Girls, Plymouth.

Births.

EWART.—On Sept. 14th, at The North House, Claybury, Essex, the wife of Charles Theodore Ewart, M.B., of a daughter.

RENNY.—On Sept. 11th, at St. Mary's House, Colchester, the wife of E. G. Renny, M.R.C.S., L.R.C.P., of a son.

Marriages.

ADAMS—GRABHAM.—On Sept. 13th, at St. Mark's Church, Surbiton, Cecil Newton, youngest son of the late Francis Adams, of Surbiton, to Beatrice, youngest daughter of the late Charles Grabham, M.D., of Pontefract, Yorkshire, and Mrs. Grabham, Surbiton.

HOWLAND-CARRINGTON.—On Sept. 11th, at St. Saviour's, Walton Street, London, S.W., Goldwin William Howland, M.B.Toronto, M.R.C.P.Lond., eldest son of the late William Holmes Howland, to Margaret Christian, only child of William T. H. Carrington, M.Inst.C.E., and Mrs. Carrington, of Clapham, Surrey.

WEBB JONES—LONG.—On Sept. 12th, at St. Mary Abbots, Kensington, Arthur Webb Jones, F.R.C.S., of Alexandria, to Lilia Bell, younger daughter of the late Captain Wakeman Lon 61st Regiment, and of Mrs. Wakeman Long.

WHITCHURCH—WILLIAMSON.—On Sept. 12th, at the Parish Church of Tempsford, Sandy, John Arnold, son of the late Nathaniel Whitchurch, Esq., M.D., of Melton Mowbray and Great Barford St. Neots, to Norah Madeline Penelope, eldest daughter of the Rev. W. Williamson, Rector of Tempsford.

Deaths.

CATTLIN.—On Sept. 12th, at 4 Westbourne Terrace, Hove, Sussex, William Cattlin, M.R.C.S.E., eldest son of the late W. A. N. Cattlin, P.R.C.S.E., aged 68.

GOODSALL.—On Sept. 14th, at 17 Devonshire Place, London, W., David Henry Goodsall, F.R.C.S., Senior Surgeon Metropolitan Hospital.

GREENWOOD.—On Sept. 10th, from pneumonia, aged 71, Henry B. Greenwood, of 15 Angel Court, London, E.C., and 25 Ladbroke Grove, Holland Park, W., only surviving son of Thomas Greenwood, M.R.C.S.E.

WHITTY.—On Sept. 11th, after a short illness, at Minna Lodge, Hunstanton, Charles Richard Whitty, M.D., second son of the late Rev. David La Touche Whitty, aged 63.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, SEPTEMBER 26, 1906. No. 13.

NOTES AND COMMENTS.

Overdosage with Trional.

A CASE presenting some unusual features was investigated by the Clerkenwell Deputy-Coroner the other day. A chemist, the employé of a drug company in Holborn, suffered much from worry, overwork, anxiety and sleeplessness, and was known to be on the habit of taking hypnotics. The matter came to the ears of the company, and the employé was dismissed with a month's salary, but he was promised reinstatement when he could show that he had conquered the drug habit. The unfortunate man went home and locked his door, and when the room was entered he was found asleep with many bottles about him. He remained in bed the next day, and seemed to be improving, for he promised to go to a drug retreat, but he died suddenly on the fifth day. The *post-mortem* showed that he had died of an overdose of trional, but the jury did not find sufficient evidence to bring in a verdict of suicide. On the other hand, the facts are strongly suggestive of such an inference, and if this were really the fact, the instance must be almost unique, for we never remember trional being taken or given with homicidal or suicidal intent. Unluckily it is not stated what quantity of trional was taken, but it must have been very large, as considerable doses have been taken in error without fatal result. Chronic poisoning by sulphonal or trional is now well recognised, but acute suicidal poisoning is not. It is a fact that should be borne in mind now that so many ladies and others take trional habitually, and buy it in tins and tablets in considerable quantities.

Co-operative Quackery.

AN amusing instance of the biter bit has come to our notice through the publication in the *Grocer* of September 15th of an article entitled "Co-operative Substitution." From it we learn that the St. Helens and District United Traders' Profit-Sharing Association are trying to get their members to boycott the ordinary patent medicines and buy similar preparations made by the Association. Now co-operative trading has developed enormously in the last two decades, and as far as the working-classes and lower middle-classes are concerned, it is quite likely that it may become practically universal; in other words, if the co-operative societies can get their members to buy patent medicines from them, the bulk of the money that now finds its way into the pockets of private advertising adventurers will flow into the common pocket of the society. While we deplore the thirst for quack drugs which exists, it must be recognised that it has largely been whetted by the advertisements of the quacks, and one certainly would be glad to hear that if any profit is made out of the sales, it will not go to those who systematically stimulate the morbid tendencies of the public mind.

A Valuable Discovery.

BUT the Co-operative Association have discovered that the prices charged by the manufacturers of quack drugs is enormously over their value, and that it is possible for much smaller prices to turn out just the same goods, and yet handsomely reimburse the sellers. Everyone knows that, as a rule, the price a pharmacist charges for pills and mixtures is considerably more than their actual cost, but this is because the pharmacist's remuneration is partly of the nature of a fee and partly of the nature of payment. Now, a manufacturer who turns out pills by the million for popular consumption has used just the amount of brains necessary to read a prescription in some pharmacopœia and dictate it to a man who can compound it. The fact that a manufacturer charges a high price for his pill is not due to the individual attention that he has bestowed on it, but to the expense he has been at in advertising it in newspapers. So that, now the St. Helens United Traders' Association have discovered this fact, and discovered also how they have been "had" over these patent medicines, they are taking to putting up their own preparations from the same sort of simple formula used by the manufacturers, and we have no doubt the therapeutic effect will be equally happy or unhappy, as the case may be.

Tetanus and the Fourth of July.

THE annual rejoicings which take place in America every Fourth of July have, as usual, been followed by an outbreak of tetanus. It is some satisfaction, however, that the number of cases has during the past few years shown a steady and marked diminution. Thus, in 1903, there were 415 cases recorded as due directly to Fourth of July celebrations, in 1904 there were 105, 104 in 1905, and 89 in the present year. This decrease of tetanus is not coincident with a decrease of total injuries, since during the same period these

have risen in number from 4,449 to 5,466. The decrease is almost certainly due, therefore, to a better care on the part of the profession in the treatment of the class of wounds most likely to give rise to tetanus. In former years tetanus commonly resulted from apparently trivial wounds caused by the explosion in the hand of blank cartridge. It has been impressed upon surgeons that the proper treatment of such cases lies in free exposure to oxygen and drainage. The prophylactic use of antitoxin has also become more common. It is to be noted as bearing out this view that almost all of the eighty-nine persons who suffered from tetanus had received no surgical treatment whatever, whereas in former years the great majority had received superficial treatment. That it is too soon to boast of a bloodless Fourth is evident when we learn that, in addition to seventy-five deaths from tetanus, there were eighty-three from other accidents directly rising out of the national celebration.

LEADING ARTICLE.

THE AWAKENING OF THE GENERAL PRACTITIONER.

THE history of social evolution is that of a slow and gradual process, in which the main inevitable characteristic is progress. So imperceptible is the motion at times that it appears to be stationary, and its existence can be detected only by the most minute and accurate observation. In this quality it may be compared to the infinitely slow progress of an Alpine glacier, or of the frozen sea of ice that surrounds the Northern Pole. With Nature, however, as with man, the end comes at length in obedience to more or less imperfectly recognised laws, no matter how great the delay at the outset. Of all social class evolutions, perhaps that of the medical profession is one of the longest delayed. Compared with other professions, as, for instance, the Church, Law, and the Services, that of Medicine is but a disorganised, neglected, plundered, and ill-rewarded drudge. In spite of its enormous potential powers as a great factor in the community she is politically impotent, and her birthright is practically sacrificed to illegal competitors on every hand. The situation, indeed, would be farcical were it not full of fierce pathos and tragedy on every hand. Parliament has laid down in detail a code of stringent rules for the professional education and examination necessary to medical qualification. Recently those regulations have been rendered more exacting and infinitely more costly by the addition of another year to the curriculum. But while Government, on the one hand, has made provision for the supply of well-educated medical men, on the other it has wholly neglected to furnish any adequate machinery for the exclusion of unqualified quacks, who are allowed to swindle and defraud the public with impunity, and to rob legitimate practitioners of their just fees. Those who practise law have to go through a special curriculum and to pass examinations before being permitted to practise as solicitors or barristers. In the field of actual professional work, however, the lawyers have taken good care to defend themselves against unqualified competition. If an outsider simply writes a letter remotely suggesting he is acting in a legal capacity, he is instantly prosecuted and invariably mulcted in a substantial fine. Yet it is surely just as important to protect the public from quacks who play havoc with life and limb as from petty rogues whose trespasses in legal preserves can result merely in desultory and trivial monetary damage. But the history of medical grievance is a thrice-told tale, and it is a relief to turn to any proposals that may have in them the germ of future reform. After all, the matter chiefly affects the general practitioner, and it will ultimately have to be settled by him. If he demands a really representative General Medical Council, or one-portal system of qualification, and adequate defence against unqualified practice, he will have to secure them with his own right hand. As regards one particular injury, namely, that of unfair hospital competition, we note with satisfaction that he is taking preliminary steps which it may be hoped will not disappear into the limbo of oblivion and futility that has swallowed up so many previous enterprises of a similar nature. The Hospitals Committee of the British Medical Association has addressed a circular letter to medical charities throughout the United Kingdom inviting consideration of a number of points connected with hospital administration. Each institution is invited to send a delegate to a central congress to be held shortly. Should it be found impossible to come to any formal or binding common basis of action, the publicity attached to the proceedings of the congress cannot fail to do good in educating both the public and the medical profession as to the facts of the case. The precise *locus standi* of the Association that asks for the inquiry may create difficulties in some quarters. On the whole, however, it will be wise not to insist too strongly upon a formality of that kind when the request comes from a body that, at any rate, represents a great numerical proportion of the medical practitioners of the United Kingdom. As a matter of plain statement, it appears that the strain of the professional struggle has become intolerable. For our own part, we are inclined to believe that much more benefit would accrue from the suppression of unqualified practice than from the reduction of hospital competition. However now that the Hospitals Committee has laid its hand to the plough, we trust there will be no looking back. Our cordial sympathy and support will be forthcoming whenever any workable scheme is formulated. Meanwhile we ask for general support from the medical profession in our warfare against quacks and quackery. Essentials to success in that campaign will be the reform of the General Medical Council and the appointment of a Royal Commission of inquiry into the whole matter.

NOTES ON CURRENT TOPICS.

Seaside Museums.

The educational value of museums is undoubtedly great if only people can be found to take an intelligent interest in them. Merely to look through a natural history museum affords an object-lesson of unconscious value to the man in the street, while to the serious scientific student such a collection simply becomes the essential complement of his books. At the same time it is to be feared that most of the museums scattered through the kingdom are, to put the matter bluntly, simply cheap pleasure-houses for the million. Even then it is difficult to estimate their suggestive value in popular enlightenment. Mr. Jonathan Hutchinson has made the gospel of local museum teaching peculiarly his own, and is spreading it far and wide with his usual thoroughness. So far as small inland towns and villages are concerned, there can be little doubt as to the good work that can be done in that way. It is not so easy to agree with the distinguished surgeon, however, when he advocates the establishment of natural history collections at seaside places. Visitors to holiday resorts of the kind would be about the last persons in the world to patronise museums. The few seaside collections we recall may be described as dismal, dusty, scrappy and shunned. The field for museums in small inland districts, where the population is less migratory and has to fill up winter as well as summer months, is another matter altogether. In this latter aspect Mr. Hutchinson's views summarise fundamental principles of sub-conscious education that are far from generally recognised.

Meat and Tuberculosis.

The full relation of flesh food to infective disease remains to be worked out. Indeed, it is still denied in certain quarters usually regarded as authoritative that tuberculosis, for instance, is spread by tuberculous meat and milk. From a practical point of view it would obviously be a simple matter of precaution to regard such tainted food as highly suspicious and to exclude it from the public supplies. The ancient Hebrew ritual, which possessed a marvellous insight into practical sanitary measures, rigorously rejected all defective carcases, a measure that is administered to the present day by the Jewish Board of Shechita. An important conference of medical officers of health was recently held in London to consider the question of supplying the public with meat from healthy home-bred cattle and sheep. It was convened by the Agricultural and Industrial Society, and the Secretary of the movement is Mr. D. Tallerman. Most of the speakers seemed to accept the proposition that human tuberculosis could be acquired by eating the flesh of tuberculous animals. The objects of the Society appear to be practical, sound, and of the utmost importance to the national public health. The Secretary pointed out that by using cold storage chambers on a large scale the meat could be dressed, coarse portions of the carcases could be tinned, and that their Society proposed to do such work for farmers, butchers, and grocers at a reasonable remuneration. At the same time the demand for home-bred meat would be greatly increased.

Unclean Medicine Bottles.

The great triumph of modern medicine, as everyone knows, depends on the prevention rather than the cure of disease. Hence the value of bacteriology, which enables the public health expert to put his finger, as it were, upon the evil-working bacillus and so arrive at first causes. His gospel amounts in the long run to the most ancient of teachings, namely, that cleanliness is next to godliness. It is astonishing the number of human maladies that owe their origin to contamination of the gross and readily preventable kind. A glance round at the many diseases arising from pollution of air, water, food, schools, dwellings, and workshops will prove the truth of that statement a thousand times over. Now turn to a particular instance—the medicine bottle. Each bottle should, properly speaking, be sterilised before physic is put into it. The average life of an ordinary dispensary phial, however, is long and full of vicissitudes. Among the latter are the domestic ashpit and the municipal dust-heap, while empty bottles are used for a vast variety of fluids from gin to hair-oil, from furniture polish to materials of unspeakable nature. Many bottles revert to their original use as receptacles for physic, and it is obvious that nothing short of absolute sterilisation by steam at a high temperature can render them safe for such a purpose. The careful medical man who dispenses his own physic has long been alive to this danger.

Distribution of Honours.

In our correspondence columns we publish a letter from a distinguished old Indian medical officer, Surgeon-General Tuson, M.D., F.R.C.S., who writes to us to draw attention to his claim to reward from the Government which he served long and faithfully. We know that the distribution of decorations and rewards is an invidious task for those in authority, but it is unfortunately the fact that merit is not the only factor that counts. Personal friendship is often allowed to decide what should be a purely official question, and preference for individuals in some cases is pushed to a glaring extent. Surgeon-General Tuson feels that he is labouring under a grievance in having his service slighted, and after trying the usual official channels he turns to us. We are sure that nobody could read the record of his services in times of war and peace without feeling that he is a man of the type that has built up our great Indian Empire. Medical officers in India are called upon to undertake duties both medical and military of the most varied character, and Surgeon-General Tuson's

services include fighting in the Mutiny and in the Wuzeeri Campaign, the charge of Simla during the cholera outbreak in 1866–1867, the sanitary charge of the great Durbar in 1876, and the tenure of many important official posts. All that he has done has earned the praise and thanks of his superiors and inferiors, and it seems to us that it would be a gracious act on the part of the Indian Government to bestow a decoration on him at one of the periodical distributions of honours.

Public Compensation for Enteric Fever—Municipal Responsibility.

AFTER the outbreak of typhoid fever at Lincoln a year or so ago, it was proved that a municipality guilty of neglect in safe-guarding its water-supply against pollution might be made responsible for damages to those suffering from illness in consequence. The question of law was not disputed, and the Town Council did in fact pay a large sum in compensation to victims of the epidemic and their relations. A similar sequel is now reported from Basingstoke where a recent outbreak of typhoid was traced to town water-supply. The Borough Council had fifty actions for damages entered against them in the High Court, the total sum claimed being nearly £4,000. In order to avoid litigation a committee of the claimants was formed, and this committee agreed to meet a committee of the Ratepayers' Association to adjust the claims. As a result the Council have agreed to pay £1,760 in settlement of the actions. This payment, we are told, has been made "without prejudice" and with "denial of liability." It is difficult to understand the value of these reservations; they may represent some legal technicality, but the fact remains that the Council have not ventured to fight the question. With the two cases of Lincoln and Basingstoke on record, it is to be hoped that Councils throughout the country, whether rural or urban, will recognise more fully their responsibilities with regard to the water-supply they control. It is satisfactory to add that the Basingstoke authority has now gone to a fresh source for their water.

The Health of Belfast.

MUCH attention has been given in the newspapers of the last few months to questions affecting the health of Belfast. It will be remembered that the Corporation are endeavouring to fix the salary of the Medical Officer of Health at so low a figure as to prevent properly qualified candidates from presenting themselves. At the moment of writing the Corporation and the Local Government Board are at a deadlock, as the latter body has declined to sanction the utterly inadequate salary proposed by the Corporation. It can hardly be maintained that the attitude of the Corporation is due to ignorance of the needs of such a city as Belfast, since they have year after year object lessons provided for them in the shape of epidemics of typhoid fever. This autumn as usual a typhoid epidemic has broken out, and shows no sign of diminution. Belfast, as much as any city in the Kingdom, requires the services of a thoroughly capable and thoroughly trained medical officer of health. It is absurd to expect a practitioner without special training and experience in sanitary work to be able to grapple with problems which require highly specialised knowledge. If the Corporation remain determined to regard the health of the people of Belfast as of no importance, it is to be hoped that the Government will take steps to make their responsibility clear. We understand that the citizens of Belfast intend shortly to hold a public meeting to demand the appointment of a Commission of Inquiry. Such a Commission would do much to direct public opinion to a grave scandal, but its further power would be very limited.

Insanity in Ireland.

THE recently published Blue Book with reference to the increase of insanity in Ireland is an important document. It deals exhaustively with the subject, and presents an authoritative collection of facts and a series of comments and conclusions that form a weighty contribution to the literature of the subject. To discuss this special report within the limits of a paragraph is obviously out of the question. The attention of readers, however, may be drawn to its appearance and we hope to deal with the matter more fully in an early issue. At the same time it may be mentioned that a prominent place is given to the influence of emigration. By draining the country of its strong and healthy members it lowers the general mental and bodily standard and leaves behind many weaklings. A number of the unfit emigrants moreover, return to Ireland. The somewhat disquieting fact is disclosed that insanity is more prevalent among Irish emigrants in America than among those coming from other countries. "Relative to their numbers," says the Report, "the Irish furnish a much larger proportion of the white foreign-born insane than any other nationality." The incessant stress and hurry of American life appears to be peculiarly unsuitable to the emotional Celtic temperament.

India and the Opium Trade.

THE awakening of the East has of late years been proclaimed in startling fashion by Japan. Signs are not wanting that China will sooner or later follow in her wake. Already the Chinese are reforming their educational methods and creating an army trained for modern warfare, not to mention the fact that their Government has recently appointed a Commission to study political economy as applied in Western civilisation. But perhaps the most significant sign of all is that contained in a lately issued edict ordering the abolition of the use of opium within the space of ten years. The average European can only dimly realise the amount of physical and moral degradation inflicted by opium-smoking upon the Chinese nation. By its discontinuance a well-nigh

incalculable drain upon the national physique will be put a stop to. The effect of the edict upon our great Indian dependency will be immediate and considerable. The local revenue derived from the opium trade with China amounts yearly to £4,500,000. The moral responsibility involved, however, in the opinion of many Englishmen far outweighs any compensatory budget advantages. To put the matter bluntly, several costly wars have been waged with China simply and solely to force upon that empire our Indian opium. The Chinese accepted the drug under protest, and later, in self-defence, grew large quantities of opium in their own country. Some idea of the iniquity of the whole proceeding may be gathered from an imaginary picture of China sending several armed expeditions against the United Kingdom, and compelling her to import from the conquerors five millions worth of alcohol. The abolition of the opium trade will remove a blot from the British administration of India.

New York Consumptive Campaign.

The energies of the National Association for the Prevention of Consumption, or rather the financial contributions of its supporters, have of late waned considerably, but there remains the palpable fact that people generally are more alive to the nature of consumption and better primed in the methods for avoiding it than they were ten years ago. Still, our campaigns against tuberculosis are rather one-horsed affairs after all, and it would really be well if the facts about the disease and its prophylaxis reached people more directly than through the medium of a half-torn notice posted on a hoarding or a warning not to spit enamelled on the seat of a 'bus. To our sanitary friends we would commend the example of the Health Department of New York, not perhaps for exact imitation, but at any rate as showing what can be done. An instrument called the stereopticon—a kind of magic lantern—is fixed in the public parks, and from it there are flashed on to screens captivating pictures of tubercle-bacilli and epigrammatic warnings against infection with tuberculosis. These shows are very popular, and large crowds stand every evening gazing at the wonders provided for their delectation, for interspersed with the serious pictures are others of a lighter and more attractive kind. There is no denying that by means such as this a large number of slum dwellers are reached who would not be amenable to education in any other way, and though to the Britisher the plan savours rather of the cheap-jack, it must be remembered that the cheap-jack is the man who caters for and reaches the poor. At any rate it may be taken for granted that it is better for the people to read on illuminated screens at night, "Don't live in a room where there is no fresh air," than that Apple's soap is the best or that Cowine is indispensable for infants.

London Medical Exhibition.

On the first five days of October, Monday to Friday inclusive, will be held the Second London Medical Exhibition at the Royal Horticultural Hall, Vincent Square, London, S.W. Last year's exhibition was one of the most successful gatherings of the kind ever organised. The reason of its popularity in the profession was doubtless due to the fact that invitations were confined to medical men. The hall will be open from 11 a.m. until 6 p.m. daily, and various attractions are provided in the way of a reception-room, light refreshments, and military bands. All medical men who have time and opportunity will do well to visit this Exhibition.

PERSONAL.

It is announced that Sir Victor Horsley has written to the President of the General Medical Council resigning his seat on the Council in order that the inconvenience of a separate election next year may be avoided.

It is stated that Dr. Frederick Taylor, of Guy's Hospital, and Dr. E. G. Graham Little, of St. Mary's are candidates for the vacancy which has arisen through the resignation of Dr. J. F. Payne from the Senate of the University of London.

Professor Ivan Petrovitsch Pawlow, professor of physiology in the University of St. Petersburg, will open the winter session of Charing Cross Hospital Medical School, on Monday, October 1st, and deliver the sixth biennial Huxley lecture, "On Recent Advances in Science and their Bearing on Medicine and Surgery," at 4 p.m. Medical practitioners can obtain cards of admission from the Dean so far as the accommodation permits.

Mr. Robert Mackey Wilson, of Dublin, has presented the sum of £1,000 to the Governing Body of Queen's College, Belfast, for the purpose of instituting a medical travelling prize to be competed for by newly-qualified medical graduates of the College. The prize will be awarded triennially, and will be of the value of one hundred pounds.

Professor Alexander Macalister will distribute the prizes to students of the Faculty of Medicine, at University College, Bristol, on October 2nd.

A Reuter telegram from Rome reports that the illness of Dr. Lapponi, physician to the Pope, has been diagnosed by Dr. Mazzoni as cancer of the stomach.

Dr. Leonard Mark will give the presidential address to the West London Medical Chirurgical Society on Friday evening, Oct. 5th. The subject will be "Art and Medicine," and the address will be illustrated by lantern-slides of some pictures and works of art in British picture galleries and museums, which are interesting from a medical point of view.

Dr. Bergmann is leaving Constantinople, but, at the Sultan's request, Dr. Bier is remaining at the palace to superintend the royal "cure."

On September 19th Dr. Booth was elected medical officer of health to the Cleethorpes U.D.C., in place of the late Dr. T. Newby.

The Lord Mayor presided at the Mansion House at a public meeting held last Thursday at 3 p.m., at which Miss Olga Nethersole gave a short address explaining the details of a Universal Woman's League she is forming, for the purpose of spreading a knowledge of and combatting the ravages of tubercular disease.

A CLINICAL LECTURE
ON
DISEASES AND INJURIES TO THE ORBIT.*

By SYDNEY STEPHENSON, M.B., F.R.C.S.

Ophthalmic Surgeon to the Evelina Hospital, the North-Eastern Hospital for Children, and the Queen Charlotte's Lying-in-Hospital.

PART I.

THE orbit is the bony socket in the skull which lodges the eyeball and other structures appertaining to the nourishment and protection of the organ of sight. It is made up of seven bones, namely, the frontal, ethmoid, sphenoid, superior maxilla, malar, lacrymal, and palate. The inner walls of the two orbits, formed by the ethmoid and lacrymal bones, are practically parallel with one another, but the outer walls, formed by the frontal bone and the lesser wing of the sphenoid, diverge considerably. The upper wall, formed by the frontal bone and the lesser wing of the sphenoid, is hollowed from side to side. The lower wall, formed by the malar, superior maxilla, and the palate bone, is concave from side to side and slopes outwards and downwards. In a singular case I saw recently there was a congenital non-differentiation of the lower orbital arch, giving a peculiar and characteristic conformation to the palpebral fissure.

The orifice of the orbit is protected against violence by strong buttresses of bone, belonging to the frontal and malar bones; upon the inner side it is shielded by the prominent nasal bones.

The orbit is lined by periosteum (sometimes called "periorbitum" in this position), continuous behind with the dura mater through the ophthalmic foramen and the sphenoidal fissure, and in front with the orbital septum. The loose attachment of the periosteum to the bone doubtless explains the facility with which hæmorrhage may occur between the two structures, as in injuries or in infantile scurvy.

The orbit has two fissures and seven foramina. The fissures are called respectively the sphenoidal and the spheno-maxillary fissure, and are destined for the transmission of nerves and blood-vessels. The sphenoidal fissure, directed obliquely upwards and outwards, lies between the greater and the lesser wing of the sphenoid bone, and connects the orbit with the middle fossa of the skull. It transmits the third, fourth, ophthalmic division of the fifth, and the sixth nerve, besides filaments of the sympathetic nerve and the ophthalmic vein. The spheno-maxillary fissure is situated in the lower wall, and connects the orbit with the zygomatic fossa. It is bridged over by plain muscular fibres (the orbitalis muscles), corresponding to a more considerable layer found in certain mammalia. It transmits the superior maxillary nerve and the infra-orbital artery. The optic foramen (the only one of any consequence in this place) lies at the apex of the orbit, between the roots of the lesser wing of the sphenoid. It transmits the optic nerve and the ophthalmic artery. It is separated by a thin plate of bone only from the sphenoidal sinus, and the optic nerve is accordingly liable to damage early in the course of tumours affecting that sinus.

Other points of interest about the orbit are (*a*) the fossa for the lacrymal gland situated under cover of the external angular process on the outer side of the orbital plate of the frontal bone; (*b*) the lacrymal groove for the lacrymal sac at the side of the nose near the inner canthus in the lacrymal and superior maxillary bones. It is crossed by an important surgical landmark in the shape of the tendon oculi; (*c*) the supra-orbital notch (or foramen) for transmission of the supra-orbital artery and nerve, lies at the junction of the inner third with the outer two-thirds of the upper margin of the orbit—it can be easily felt in most subjects; (*d*) the pulley for the superior oblique muscle, marked by a tiny bony tubercle, can be felt somewhat behind the supra-orbital notch and the internal angular process of the frontal bone; (*e*) the infra-orbital foramen opens on the anterior surface of the superior maxillary bone, 5mm. to 10mm. below the orbit. It is the termination of the infra-orbital canal, which lies in the floor of the orbit, and which transmits the infra-orbital nerve and artery from the zygomatic fossa to the skin of the face between nose, eye, and upper lip.

The orbit is surrounded by a number of air-sinuses, viz., the frontal, maxillary, ethmoidal, and sphenoidal, together with the nasal cavities. The frontal sinus is a space lying between the two tables of the skull, one on each side of the middle line, behind the nasal eminences of the frontal bone. They are lined by mucous membrane, and are in free communication by the infundibulum with the nasal cavity. They fail to reach any marked development until puberty, and show great individual variations in size and in shape. They are usually separated from one another by a vertical shell of bone, but that may be absent or incomplete, so that there may be one large sinus only. Inflammation of the sinus may be due to injury, but more commonly appears to be secondary to nasal disease. Retention of secretion may be indicated by a bulging near the root of the nose, that is to say, of the orbital plate of the frontal bone. The maxillary antrum, or antrum of Highmore, is a pyramidal cavity, lined with mucous membrane, in the body of the superior maxillary bone. Its orifice communicates with the nasal cavity. It varies in size and shape, but is the largest air-sinus. The roots of the canine or first molar teeth frequently project through the alveolus into the space. Its upper wall forms part of the floor of the orbit, and may be bulged when the antrum is filled with fluid, pus, or a solid growth. Antral disease results from (1) decayed and septic teeth, and (2) nasal inflammation. The ethmoidal and sphenoidal sinuses lie respectively in the ethmoid and the sphenoid bones.

The contents of the orbit include the eyeball, optic nerve, lacrymal gland, ocular muscles, levator palpebræ superioris, nerves, vessels, fasciæ, and granular fat.

The optic nerve enters the orbit through the optic foramen, and takes a curved course to end in the eyeball as the retina. This sigmoid curve of the nerve allows free movements of the eyeball to take place. It accounts for the fact that definite exophthalmos need not necessarily interfere with the conductivity of the nerve. Indeed, exophthalmos, generally speaking, must be pronounced to entail either organic changes in the nerve or mechanical limitation of the ocular movements. A rapidly-produced exophthalmos is much more likely to do mischief than one of gradual development.

The arteries are branches of the ophthalmic, which enters the orbit through the optic foramen. The veins are two in number, one superior and the other inferior. They reach the cavernous sinus by passing between the heads of the external rectus muscle through the sphenoidal fissure. They anastomose with the veins of the forehead, and evidence of this communication may sometimes be found when the cavernous sinus is occluded by a thrombus. The fact

*Delivered July 18th, 1906, in the Post-Graduate Course of Ophthalmology in the University of Oxford.

that the superior ophthalmic veins of the two sides are in free communication, behind by the cavernous, circular, and transverse sinuses, and in front by an anastomosis over the bridge of the nose, has led Motais to suggest (*Recueil des Travaux de Congres International d'Ophtalmologie*, Sept., 1904) that the infection in sympathetic ophthalmitis may travel from one eye to the other by this venous channel.

The central artery of the retina, a branch of the ophthalmic, enters the optic nerve 10mm. to 20mm. behind the eyeball. The central vein emerges from the nerve at the same spot, and runs either directly into the cavernous sinus or first joins the superior ophthalmic vein. This accounts for the distension of the retinal veins seen with the ophthalmoscope when the cavernous sinus is occluded, or when it is placed in morbid communication with the internal carotid artery, as in some cases of pulsating exophthalmos.

The nerves are numerous, and comprise the third, fourth, and sixth cranials, and the first and second branches of the trigeminus. The ophthalmic ganglion, a tiny reddish body, lies at the hinder part of the orbit, between the optic nerve and the external rectus muscle. Its sensory root comes from the fifth, its motor root from the third, and its sympathetic root from the cavernous plexus. The short ciliary nerves ten or so in number, run from the ganglion along the optic nerve to the eyeball.

Before describing as briefly as may be some of the more important diseases of the orbit, a few words may be usefully said with regard to injuries. Injuries of the orbit, which include contusions, fracture of the bones, and penetrating wounds with or without the lodgment of foreign bodies, are not common accidents.

As regards contusions, J. Jameson Evans (*British Medical Journal*, July 8th, 1905) has recently reported a series of cases where a blow upon one external angular process was followed by sudden impairment of sight in the corresponding eye. Additional symptoms were loss of the greater part of the temporal field of vision, and in the course of a few weeks atrophy of the optic papilla. Evans concludes that these symptoms are produced by contusion of the nasal fibres of the optic nerve by *contre-coup*. The opposite side of the nerve is shielded by the ophthalmic artery, which winds round its outer side from below.

A serious injury is dislocation—or, rather, avulsion—of the eyeball. This injury is sometimes self-inflicted by a frenzied maniac, or may be done by an antagonist during the course of a quarrel. Some twenty cases have been known to occur in the course of difficult labour. In most of these latter cases there has co-existed a depression of the cranial bones above the orbit of the affected side, so that Thomson and Buchanan (*Trans. Ophthal. Society*, vol. XXIII., 1903, p. 296) are undoubtedly correct in designating the injury as "extrusion" of the eyeball rather than as "dislocation." As a rule, the injury has been due to forceps, but at least one case is known (*Ophthalmic Review*, July, 1906) where the eye was extruded apparently by uterine contraction alone. In a celebrated case quoted by De Wecker (*Annales d'Oculistique*, 1896, T. CXVI., p. 40) an accoucheur mistaking a face for a buttock presentation, managed to gouge out the baby's eye with his finger. Another similar case is on record.

Division of the trunk of the optic nerve may be another consequence of penetrating wounds of the orbit. Blindness will be the immediate and optic atrophy the remote result of such an accident. A case of this kind was mentioned by the late George Lawson in his "Injuries of the Eye, Orbit, and Eyelids" (1867). A clergyman, while shooting, stooped quickly to pick up a bird that had fallen among some bulrushes. He felt a sharp pain in one eye, and found that he had lost the sight of that eye. About a month after receipt of the injury, the patient discovered a small hard lump projecting from beneath the eyeball. He pulled at the lump, and was astonished to find that he had drawn from his orbit the head of a bulrush about 1½ inches in length. Cases are known where both optic nerves have been divided by a bullet passing across the orbit on each side.

Some truly remarkable cases have been reported in which foreign bodies have become lodged in the orbit, often without the patient having any suspicion of the nature of the injury. What is perhaps the leading case of this description was recorded by Brudenell Carter many years ago. An iron hat-peg, upwards of three inches in length and weighing twenty-five scruples, lay impacted in the orbit for several days without the patient's knowledge. The man, whilst intoxicated, had fallen down some stairs against the peg, which had penetrated the tissues of the orbit and broken off short. Another famous case was that of Nélaton, who, three years after an injury, removed from the orbit of a young man the ivory handle of an umbrella 1⅛ inches in length.

Blindness following injuries to the orbit or skull are now known to be due to fracture of the roof of the orbit and optic foramen, and not to reflex influence, as the earlier writers assumed. Hölder and Berlin have shown that a fracture of the base may be complicated with fissures in the orbit, and in that way may produce loss of sight. Deep conjunctival ecchymosis and, later, atrophy of the optic disc are likely to be met with in such cases. Then, as already stated, *contre-coup* may account for some of the cases.

Some attention has lately been paid, especially by Nettleship (*Trans. Ophthal. Society*, Vol. XXI., 1901, p. 102) to what have been termed "indirect gunshot injuries" as affecting the eye. In these cases the passage of a bullet through the orbit is followed at once by bleeding into the vitreous, and when the hæmorrhage clears up, serious lesions are found in the eye. It is important to note that in these cases the eyeball has not been directly injured by the projectile. These curious injuries (believed to be due to intense tissue vibrations set up by the bullet impinging upon the eyeball and damaging its contents) may entail complete blindness. They are mentioned here because they may be confused with instances in which the optic nerve or nerves have been cut across by a shot. Indeed, in some of the cases mentioned by Nettleship there was reason for thinking that the two conditions were combined.

The diseases of the orbit may be divided into two primary classes:—(1) Inflammatory; and (2) non-inflammatory affections.

(1) Inflammatory affections are marked by pain, redness and swelling of the eyelids, accompanied, as a rule, by exophthalmos, limitation of the movements of the eyeball, and fever. They include periostitis, cellulitis, tenonitis, and thrombosis of the cavernous sinus.

The symptoms of periostitis differ according to the position of the inflamed part, whether superficial or deep. In the common form, where the rim of the orbit is involved, there is no disturbance of the general health worth mentioning. The symptoms are purely local, and include deformity and swelling, tenderness, pain, some œdema of the corresponding eyelid, and, perhaps, partial chemosis of the ocular conjunctiva. The process often undergoes complete revolution. It may, however, lead to the local development of osseous deposits or of pus. After the abscess has burst or been opened, a fistula will remain, through which roughened bone may be felt with a surgical probe. Such fistulæ or sinuses, more correctly, which are far from uncommon in tuberculous children, are generally placed at the lower and outer edge of the orbit, probably because that spot is more subject to contusions than others. They often entail eversion of the affected eyelid (ectropion).

On the other hand, let us suppose that inflammation has attacked the periosteum in the depths of the orbit. The symptoms in that case will be intensified. Thus, there will be deep-seated pain, more or less fever, and general malaise, redness and swelling of the eyelids, chemosis of the conjunctiva, and protrusion of the eyeball, with limitation of movement. As regards

the last two signs, it may be noted that (*a*) the eyeball, as a rule, is displaced away from the lesion, and (*b*) restriction of movement is directly proportional to the degree of exophthalmos, since it is mainly due to stretching of the recti muscles and optic nerve.

Should a deep-seated abscess form, it may be impossible to distinguish the condition from cellulitis. Tenderness of the rim of the orbit is believed by some to indicate periostitis as opposed to cellulitis, but I should not myself be inclined to lay much stress on that point. The common causes of periostitis are tubercle, syphilis, infection, and injury. In children, suspect tuberculosis; in adults, syphilis.

Inflammation of the cellular tissue of the orbit, or cellulitis, may follow injuries or operations, or it may occur as a complication of erysipelas, pyæmia, or specific fevers, or it may be produced by extension from neighbouring parts, as the ethmoidal or sphenoidal cells, the nasal cavity, or the antrum of Highmore. The cause, however, is sometimes quite obscure. This serious malady may prove fatal from extension to the cranial cavity.

There is much dusky swelling of the eyelids; the side of the face is puffy, chemosis is present; the eyeball is thrust markedly forwards, and its movements are impaired or altogether lost. Vision, according to the state of the optic nerve, may or may not be affected. There is severe pain, especially in the orbital region. Fever and headache are always present, and the patient is often seriously ill. The symptoms may subside, but usually go on to the formation of pus, orbital abscess. If the collection be not evacuated surgically the pus will sooner or later burst through the conjunctiva or the skin of the eyelids. Extension to the brain will be indicated by the advent of cerebral symptoms—as, for example, violent headache, rigors, vomiting, slow pulse, and mental hebetude. Thrombosis of the orbital veins is probably present in all severe cases.

Cellulitis as it occurs in very young children deserves a word of passing mention. The affection is rare, if we may judge from the fact that it is scarcely alluded to in literature, although Leplat (*Annales d'Oculistique*, January, 1898) described a case in an infant of fifteen days, and Trousseau (*Bull. et Mem. de la Société Française d'Ophtalmologie*, 1898, p. 57) two such cases in children, æt. respectively 9 weeks and 9 months. In one of Trousseau's patients the cornea perforated five days after evacuation of the orbital abscess. They all terminated favourably. The etiology of the disease as it occurs in infants is obscure. I venture to suggest, however, that it may be due to infection gaining the orbit by means of the pituitary mucous membrane, inoculated with pyogenic microorganisms from the mother's genital tract during or immediately after the act of birth. The fact is not without significance that in two of my patients coryza coincided with cellulitis.

In older children, I believe, a so-called cellulitis is generally only a manifestation of a process akin to if not actually identical with infective ostitis (acute necrosis).

The capsule of tenon is a layer of fascia surrounding the greater part of the eyeball, so as to favour free movement. Behind, it blends with the sclera at the point where the ciliary vessels and nerve enter the eyeball, and in front it is attached to the limbus of the cornea. Its processes invest the several muscles inserted into the sclerotic coat, while extensions of the fascia to the walls of the orbit, known as "check ligaments," help to keep the eyeball in position. The capsule is lined with endothelial cells, and is, in fact, a lymph space.

Primary tenonitis is extremely rare, but may result from septic infection, as after squint operations, or as a sequel to some specific ailment, as rheumatism, gonorrhœa, or influenza. The capsule may become inflamed as a complication of existing eye disease, as panophthalmitis. The symptoms include redness and swelling of the eyelids, chemosis, and slight exophthalmos. The movements of the eyeball are more or less hampered, and cause distress. The disease may terminate in resolution or in suppuration, and Jocqs (*La Clinique Ophtalmologique*, May 25th, 1905) has reported a case where the latter event ended in death.

As tenonitis is an uncommon disease, I may give brief details of a case recently under my care. A man, æt. 47, was seen by me at the Kensington General Hospital on March 14th last, complaining that both his eyes had been inflamed for two days. He had been feeling poorly for about a fortnight. Upon examination there was marked fleshy chemosis of the lower half of each eyeball, the upper half being merely reddened and not much swollen. The œdematous ocular conjunctiva projected from between the eyelids, so as to form a conspicuous, red, and unsightly mass. Movements of the globe were somewhat restricted and uncomfortable. Corneæ bright and clear; pupils equal and active. No discharge present. Tension normal. Three days later the ocular condition was considerably improved, but the patient was clearly suffering from an attack of influenza, probably in the nature of a relapse. The man made a good recovery.

A definite history of infection and the milder symptoms should serve to distinguish tenonitis from periostitis or cellulitis of the orbit. Although not a primary disease of the orbit, yet thrombosis of the cavernous sinus may be mentioned here, since it is likely to be confused with cellulitis. It is exceedingly rare and generally fatal. It may be due either to simple or to infective thrombi. Its commonest cause appears to be septic foci about the face, caries of the petrous bone, fractures of the skull, orbital cellulitis, or erysipelas. It differs from any of the diseases so far described in the fact that it tends in most cases to affect both eyes, not simultaneously, but one after the other, by spread through the intercavernous sinus. It is marked by serious cerebral symptoms—as headache, delirium, vomiting, and stupor, and by local signs, of which the more important are swelling of the lids and conjunctiva, exophthalmos, limitation of movement, paralysis of the third or of other cranial nerves passing through the sinus, marked distension of the retinal veins, and pain in the first division of the fifth nerve, as evidenced by intense frontal headache and neuralgia. A painful œdema in the mastoid region (Greisinger's sign) is sometimes present, and is due to interference with the circulation through the occipital veins. To sum up, this affection presents four somewhat characteristic signs:—(1) It tends sooner or later to become bilateral; (2) it is associated with marked distension of the retinal veins, and possibly with thrombosis; (3) it may be accompanied by œdema in the region of the mastoid process; and (4) it is now and then associated with enlargement of the frontal veins, due to the blood passing through the orbito-facial anastomosis.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by Sydney Stephenson, M.B.Ed., F.R.C.S., Ophthalmic Surgeon to the Evelina Hospital, the North-Eastern Hospital for Children, and Queen Charlotte's Lying-In Hospital, on "Diseases and Injuries of the Orbit." Part II. Lecture delivered in the University of Oxford on July 18th, 1906.*

ORIGINAL PAPERS.

MEASLES AND ITS PREVENTION.

By JOHN C. THRESH, D.Sc., M.D., D.P.H.,

Lecturer on Public Health, London Hospital Medical College; Medical Officer of Health to the County of Essex.

Measles affects the sexes about equally, and no age, however advanced, affords complete protection. Infants have been born with the disease developed, and aged people on occasions have been attacked. Where the

disease has been imported into communities which have hitherto been free, or at least not affected for a generation, people at all ages were attacked and often the mortality has been frightful. In countries where the disease is always more or less prevalent adults are rarely attacked, simply because so large a proportion have suffered from the disease in infancy, and one attack affords such complete protection that a second attack is practically unknown. Children aged between 2 and 5 years appear to be most prone to infection, but the disease is most fatal to children under 2 years. Sixty per cent. of the deaths which occur from measles are of children under 2 years of age, 30 per cent. of children between 2 and 5 years, 8 per cent. of children between 5 and 10 years, leaving only 2 per cent. for children and others over 10.

Measles has a tendency to occur in epidemics. These are especially marked in large urban communities and occur at intervals of two to three years. This periodicity is not so well marked in rural communities. In large towns the disease is always present, the maximum number of cases occurring about Christmas. There is then a rapid decline until February, when an increase again occurs and continues until June. Again there is a decrease which continues to September, when the minimum is reached, followed by a more rapid increase to the maximum in December.

In country districts this seasonal curve is not followed. Usually the disease becomes epidemic in a parish and then entirely disappears therefrom. The infection may spread to adjoining parishes, where the same phenomena are observed. The danger of an epidemic outburst therefore is greatest when the disease is introduced into a parish from which it has been absent two or three years, and especially if it is introduced in the autumn or early summer, when for some reason it has a greater tendency to spread.

In some outbreaks the disease appears to be of a mild type, in others severe. For example, in 1904, when measles was notifiable in certain districts in the county, 1,010 cases were notified in Colchester with 29 deaths, or about 1 death per 35 children attacked. In Ilford there were 805 cases notified and only 5 deaths, or 1 death per 161 children attacked. This variation in fatality I shall have to refer to later.

Measles is not known to have any relation to soil. It does not appear to be transmitted by drinking water, or by milk or any article of food. Nor does it appear to be related to any disease occurring in animals which might be transmissible to man. The infection is probably on occasions carried by articles of clothing and other fomites, but the only manner in which it is usually conveyed is from person to person by inhalation. The infective matter, probably a micro-organism not yet isolated, is given off by the breath and from the discharges from the mouth, nose and eyes, and it is of the utmost importance to note that a patient is infectious from the earliest onset of the disease, certainly for some days prior to the attack being so far developed as to render its diagnosis certain. For 12 to 14 days after becoming infected the patient appears quite well, then he exhibits all the symptoms of a common cold, he is feverish, and there is "running" of the nose and eyes. On the fourth day from the onset of these symptoms the rash appears, usually first showing on the forehead. Some days later the rash fades and is often followed by a "branny" desquamation. These branny scales are usually regarded as "infective," but the proof of this is far from conclusive, but a patient cannot be considered free from infection until the desquamation is complete, or until three weeks have elapsed from the appearance of the rash.

The most dangerous and most fatal complication, especially liable to occur if the patient is not properly nursed and tended, is broncho-pneumonia (inflammation of the lungs and bronchial tubes), and it is this complication which is chiefly responsible for the deaths following measles. If recovery occurs the lungs may be permanently damaged, and the patient at a later date fall a victim to tuberculosis (consumption).

From what has been said it is obvious, I think, that the extent and severity of the disease depends upon three factors: (1) The virulence of the infecting agent, (2) the physical and general well-being of the children, and (3) the sanitary condition of their environment. With reference to the first, the virulence of the infecting agent, I need say very little, as at present it is beyond our control. There are those who deny that there is any variation in virulence, but this I cannot believe. I do not see how we can explain a fatality of 3 per cent. amongst the children in Colchester during 1904, with a fatality of much less than 1 per cent. in Ilford in the same year. I will admit that from my knowledge of the two towns I should have expected a lower mortality in Ilford than in Colchester, but the conditions of the people in the two towns do not vary to such an extent as to explain this great difference.

The physical well-being of the children and their bodily condition are important factors. If a large proportion of the children have been rendered immune by an attack, the risk of the disease becoming epidemic is diminished. If they are in robust health and well and properly fed, and kept in a condition of cleanliness and have acquired clean habits, they are less likely to be attacked, and if attacked the disease is less likely to be severe. It is a fact, observed by all medical men of experience, that measles is far more fatal amongst the children of the poor than amongst the children of the well-to-do (or of the better educated class). This is in part due to the causes just described, but also to the third factor remaining to be considered, the environment. By this I mean the sanitary condition of the dwellings and of the parish, and other conditions due to the care and attention or ignorance and neglect of parents. Dirt, squalor, overcrowding of people in houses, and of houses on space, all tend to facilitate the spread of infection and to increase the severity of the disease. Want of isolation, lack of nursing, inattention to the child, especially when the first symptoms are observed and when it is becoming convalescent, the outcome of ignorance and neglect, are even more important, possibly they are the most important factors in the production of epidemics and in increasing the fatality. It is also the carelessness or ignorance on the part of parents which is usually the cause of the introduction of the infection into schools, the children being sent to school when they ought to be under supervision at home. When infective children have been allowed to attend school (day school or Sunday school) an epidemic is inevitable unless the majority of the children have been rendered immune during a recent outbreak. Finally, parents generally still regard measles as a trivial affection, and can with difficulty be persuaded to take the necessary steps to guard against the spread of infection.

From what has been already said it will be obvious that there are special difficulties to be contended with in dealing with measles. The chief are (1) the extreme infectiousness in the early stages before the true nature of the disease is obvious, (2) the difficulty of obtaining early notification of cases, and (3) the ignorance and apathy of parents.

What steps can be taken under the circumstances to control the disease? And, more particularly, what are the measures which can be taken by the sanitary authorities? These can be considered under three heads:—

1. The obtaining of early information of cases occurring in the district.

2. Measures which may be taken to prevent extension of the infection in the houses invaded.

3. Measures for checking the spread from house to house or from family to family throughout the invaded district.

Taking these in order, we have first to consider how best to obtain an early intimation of the presence of measles, and naturally the question of making the disease compulsorily notifiable under the Infectious Diseases Notification Act suggests itself. This has been tried in very many districts, and in almost every

case it has, finally, been abandoned. Amongst the poor a medical man is rarely called in to treat a case of measles, unless at a late stage, when some serious complication has occurred, and the parents, whose duty it would be to notify, always plead ignorance, alleging that they thought the disease was German measles, nettle rash, teething rash, or something of this kind, and, as it is rarely possible to prove that they knew the disease to be measles, the Act becomes, practically, a dead letter. Moreover, Sanitary Authorities, finding that compulsory notification is very expensive and has apparently little effect in reducing the prevalence of the disease, are not anxious to prolong the experiment.

More important than the mere notification of the majority of cases, which is what compulsory notification effects, is the notification of the very earliest case or cases which occur in a district (I now more particularly refer to rural districts, where the disease often disappears entirely for a time), and of the fresh houses invaded. The persons most likely to hear of such cases are, not the medical practitioner, but the schoolmaster, the school Attendance Officer, the district visitor or parish nurse, and the clergyman or minister of the parish. As measles is a disease of great importance to the Education Authority, it appears to me to be very desirable from the educational point of view that they should obtain early information with reference to the introduction of the disease into any parish, and that the Attendance Officer, if instructed to make the necessary inquiries, would be best able to obtain the information required. If he were instructed to make such inquiries, and received a small fee for each family notified, probably this would answer every purpose. I am of opinion that in the course of time there will have to be a medical officer appointed to every school or group of schools, and that the attendance officers will have to make more full and careful inquiries, not merely as to the cause of absence of children, but as to the conditions likely to cause the absence of children, such as the presence of measles, whooping cough, mumps, &c., and that these reports will have to be submitted, weekly or more frequently, to the medical officer. At present I merely suggest for consideration whether the Attendance Officer's services could not be utilised in some way. Failing this we must fall back upon the schoolmaster and schoolmistress, and with the approval of the school authorities, contrive to get them to notify any suspicious case which comes to their knowledge.

Voluntary notification by parents might also be encouraged, but I fail to see how this can be done. If hand bills are distributed during periods when measles is not prevalent, people take no interest in them, and if distributed during an epidemic they are of very little good. The best time to distribute them would be when the disease has first been introduced, in the hope that the people would be inclined to make some little effort to prevent their own households being invaded. This has been done in some districts for years past, and probably some good has resulted therefrom. One clergyman, who thoroughly approves of the attempt to instruct the people by means of leaflets, thinks that there is more information given on them than the people care to acquire, and that less matter and larger type would ensure their being more widely read and the suggestions given being more generally acted upon.

Information having been obtained of early cases, the medical officer and inspector can give advice to parents in the infected households and by frequently visiting endeavour to secure the advice being acted upon. Children from infected families are then excluded from school, and on occasions children who have been in contact with infected persons may be excluded until it is certain that they have not been infected. The medical officer or inspector can also make enquiries as to the source of infection, a course which often results in the discovery of previously unsuspected cases, the very cases which, if not detected, continue to spread infection. This search for mild cases of infectious disease is of the very greatest importance, and I believe that money spent in such investigations and in watching over infected families would do far more good than many times the amount spent in providing isolation accommodation. Of course the ideal condition is the thorough search for mild cases, and the isolation of all infectious cases, but as both are usually impossible I lay greater stress on the former, as without this the isolation of the well-marked cases only cannot be of much if any benefit, and certainly is costly.

For the prevention of the spread of infection in the family and in the community, it has been suggested that hospital accommodation should be provided for cases which occur in houses in which isolation at home is impossible. The provision of a larger proportion of houses with three bedrooms would markedly diminish the number of these cases. Experience with other diseases has not been sufficiently encouraging for me to recommend hospital isolation, especially as such isolation is less likely to be beneficial in case of measles than in cases of scarlet fever and diphtheria, since the disease is infectious at a much earlier stage, and in the majority of cases the infection would have spread in a household before the disease was sufficiently developed to justify removal of the patient to a hospital. We must, therefore, at present be content with enforcing the isolation of patients, as far as practicable, in their own homes. This means constant supervision by the officials. Measles should be considered a dangerous infectious disorder under the Public Health Act, Sec. 126, and parents warned that if they do anything tending to spread infection they will be liable to a penalty of £5. This raises the question whether a disease which is not compulsorily notifiable can be held to be a dangerous infectious disease under this section. This question is really one for the magistrates to decide.

The infected children should remain isolated on the infected premises until the medical officer certifies that they are free from infection, and this raises another important question, viz., can they be considered free from infection unless their clothing and the house generally has been disinfected? To disinfect after every case of measles would involve a large amount of extra work and a considerable expenditure, and I have grave doubts whether the expense would be commensurate with the results if the process were carried out as a matter of routine. I do think, however, that it would be well to insist on thorough disinfection in sporadic cases, that is, in the odd cases which occur when there is no epidemic prevalence. It would probably tend to prevent such epidemic prevalence and be worth trying.

The attendance of children at day and Sunday schools and of persons from infected families at public gatherings also requires attention. All children from an infected house should be excluded from day and Sunday schools, and notice to this effect should be given both to the parents and the school authorities. School closure is only justified when it becomes obvious that the infection is being spread by school attendance. and that all other means of arresting the spread are likely to prove unavailing. Unfortunately the exclusion of scholars entails a serious loss of grant to a school, and this injustice should be remedied. It is a matter, however, which concerns the Education Authority far more than the Sanitary Authority and may safely be left to them.

When schools have been invaded and subsequently closed, the opportunity should be taken to thoroughly clean down the school premises, and the disinfection of the walls, roofs, floors, desks, &c., by a powerful germicidal solution is desirable. Probably also the books &c., could be submitted to some process of disinfection.

Persons from infected houses should not attend public gatherings, especially if children are likely also to be present. This can only be brought about by moral suasion. I am afraid we cannot legally enforce such abstinence.

In certain cases it might be desirable thar a person

should be restrained from continuing his or her occupation, but there is no legal power to enforce this. A woman carrying on the business of a dressmaker cannot be compelled to cease her avocation, and washing may be taken in at an infected house. Scarlet fever and small-pox alone are mentioned under the Factories and Workshop Acts, but if measles is considered a dangerous infectious disorder under the Public Health Act, probably Sec. 126 could be so interpreted as to enable us to prevent the sending out of clothing from infected premises. The authority in such cases should have power to pay compensation.

The disease may possibly also be spread by books from a public library, and where such libraries exist the librarian should be notified so that he neither gives out to nor receives from an infected house any book until the premises have been certified free from infection, and any book which has been on such premises should be destroyed or disinfected.

The taking of all the above precautions means an efficient sanitary staff, sufficiently large to discharge all these duties during ordinary times, supplemented, if necessary, by temporary additions during epidemic periods.

In conclusion, I must observe that all the efforts of the sanitary authority must be more or less futile unless the apathy and ignorance of the people can be overcome. With the present generation possibly little can be done, but I think that a most important factor is the provision of district nurses, nurses living and working in our villages among the people, gaining their confidence, helping them in their affliction, and capable of advising them not only how to nurse the sick but how to prevent sickness. Such nurses are at work in a great many parishes, and no doubt in time one will be found in every parish, and their services will lighten the work of the sanitary inspector and of the medical officer. For the coming generation our hopes must rest upon the efforts of the education authorities. If children are taught the value of health, and how to maintain it, the knowledge must be of use to them in after life, and the next generation may come to regard all infectious diseases as more or less preventable, and may be more inclined to listen to advice given to them, and to co-operate more cordially with the sanitary authority and their officers in their efforts to improve the sanitary condition of their district, and to reduce the incidence of disease.

NOTES ON THE REPEATED IODINE DRESSING IN PUERPERAL INFECTIONS.

By E. CABANES, M.D.
Assistant Professor at the School of Medicine, Algiers.

In March, 1904, I brought before the Medica Society of Algiers the results obtained by me in the treatment of eleven cases of puerperal infection by means of the repeated iodine dressing. I may recall that this dressing comprises the introduction into the uterine cavity. previously curetted if necessary, of strips of gauze of suitable dimensions, steeped in a 4 per cent. aqueous solution of iodine. These results were extremely satisfactory, for the patients thus treated were all gravely infected, some were suffering from endometritis with fœtid lochia, and false membranes on the cervix, vulva, or vagina, a high temperature and a rapid pulse; others presented the classic clinical symptoms of incipient septicæmia or pelviperitonitis. Yet all of them made rapid recovery. I drew certain conclusions from my observations—viz., (1) that the dressing might safely be re-applied several times to the infected uterus; (2) that it should be applied twice daily to obtain the best results and to bring back the temperature and the pulse to normal (*a*); (3) that its repeated application promptly arrests the further progress of suppurative puerperal endometritis, and (4) that it may be relied upon to check even advanced cases of endometritis as well as commencing septicæmia; that it is valueless in generalised peritonitis but may render service in subacute pelviperitonitis with plastic tendencies and in cases of septicæmia, by removing the original source of infection.

Since the publication of these notes the results of the method of treatment introduced by Bonnaire have confirmed my views. Bonnaire applies a swab steeped in iodine solution to the interior of the infected uterus (1) when perchloride injections have failed to arrest the progress of the infection; (2) as a preliminary to curetting the uterus, in which case, in order to avert the temporary rise of temperature consequent upon the absorption of infective products disturbed by the curette, the so-called uterine reinfection, the iodine solution is applied three hours before the intervention.

The perusal of the cases set forth in Aumond's thesis (*b*) convinces one of the value of iodine as a local application in infected conditions of the uterus, although the cases he mentions are, it is true, for the most part of moderate severity. In severe cases of infection I hold that swabbing out the cavity with iodine is not sufficient to bring about recovery, and for this reason I still adhere to the periodical dressing as in the past, except that I make an iodine injection before carrying out the preliminary curettage. I am enabled to place on record three other cases of successful treatment and to complete my notes of one of the previous cases.

Case I.—This is a case of puerperal infection already mentioned in my previous communication. The patient had been delivered a week previously by a midwife who had already infected five other parturients. After five days' high fever (38° to 40° C.) she was seized with a severe rigor that lasted twenty minutes. She presented the characteristic facies of infection. The cervix was grey and bathed in pus. In dressing her we removed about half-a-tumbler of blood-stained pus. Three dressings were applied in two days after the curettage, when the fever fell and the pulse became normal. This is an instance of grave infection rapidly arrested in its course. The patient was cured after three dressings followed by irrigations of boiled water.

Case II.—Mrs. X., æt. 28, primipara, was delivered after a normal labour on December 1st. A week later she developed symptoms of infection, pulse 130, temperature 38·5° C. The uterus was enlarged and tender and pus escaped from the cervix. The iodine dressing was applied thrice, and as the uterine discharge persisted I curetted the uterus on the 10th, after which three more dressings were applied. On the 12th the temperature had fallen to 37·9° C., and the uterus was merely washed out. On the 13th the pulse rose to 120 and the temperature to 38·4° C, but matters returned to normal after three more dressings. The uterus was merely washed out daily until the 17th, when a slight recrudescence of the symptoms led to two more dressings being introduced, after which there was no return of the fever although some ten more dressings had to be employed before the obstinate uterine discharge was finally arrested. This case shows that a short period of iodine dressing is not sufficient to do more than afford temporary relief, and that to obtain permanent results the dressings must be repeated; also that iodine injections are quite inadequate. It will be noted that twenty dressings had to be employed to stop an obstinate uterine discharge and that these gave rise to no constitutional disturbance.

Case III.—Mrs. X., primipara, æt. 18, delivered May 23rd, 1905. When first seen she was lying on a pile of soil-stained sacks. The vulva, etc., was carefully cleansed and after delivery the uterus was washed out with a weak solution of phenosalyl. The perineum was ruptured. The same evening the pulse rate was 120 and the temperature 38·4° C. On the following day the symptoms pointed to acute infection extending from the vulva to the endometrium. Pulse 130, temperature 39°. The complexion was ashen and she

(*a*) *Bulletin Medical de l'Algerie*, pp. 185, 1904.

(*b*) Aumond: De l'iode comme opique tuterine dans les infections puerperales. Paris: Thesis, April, 1904.

had several severe rigors, with occasional vomiting and diarrhœa. The abdomen was tympanitic. From the vulva wound, which was covered with exudation, inflamed lymphatics were seen ramifying on the inner side of the thighs and the left buttocks. The cervix was covered with false membranes. The vulval wound was cleansed with oxygenised water and the uterus packed lightly with iodized gauze; later on the uterus cavity was curetted. Seven dressings in four days sufficed to arrest the course of the infection and bring about complete defervescence. After the fifth day only irrigations with boiled water were employed.

CASE IV.—Madame C.M., primipara, normal labour. Five days later the temperature rose to 39·4° with a pulse of 100. The patient, who felt very weak, had had two severe rigors with vomiting and diarrhœa. The belly was distended. The cervix was covered with false membranes and the lochia were very fœtid. In spite of two perchloride irrigations the temperature on the following day was still high, so I curetted the uterus, removing some decomposing placental *debris*. This was followed by the introduction of gauze steeped in a 4 per cent. iodine solution. After six dressings the general condition had improved, although the pulse was still 100. It was decided, however, to substitute injections of perchloride solution experimentally. Three days later the pulse and temperature suddenly went up and the patient complained of sharp pain in the right iliac fossa. The dressings were resumed for the following five days, when the infection was evidently arrested. In this instance the injections of Larnier's fluid were deliberately substituted in order to prove the superiority of the iodine dressings and the result unquestionably proved this superiority. Some fifteen dressings were required in all but a less number would doubtless have sufficed had they been continuous.

These further cases fully confirm the deductions drawn from my first series of observations—viz., (1) The iodised dressing is a sure and powerful means of combatting puerperal infection. The superiority of the iodine dressing over mere injections is obvious and the rapidity of its action is often manifested by an improvement in grave cases within a few hours. The cardinal symptoms of infection usually subside within three days and the general condition correspondingly improves. The final cure is obtained more slowly and after a variable lapse of time. The dressing is particularly efficacious when there is purulent or fœtid endometritis, and our results have been equally satisfactory in several cases of incipient septicæmia. It proved of no avail in a case of acute peritonitis following abortion recently under my care; (2) the dressing is absolutely innocuous, for never in the course of the infections have we ever seen any symptoms of intoxication. Some of the patients had as many as fifteen to twenty dressings without any apparent inconvenience.

Among the earlier patients, going back from one to two years, none has suffered from any deformity of the cervix or stenosis and in none has there been any persistent metritis. The menstrual periods have returned normally and were unattended by pain. Two of the patients have since been delivered at term after subsequent pregnancies.

THE ANTI-MALARIAL CAMPAIGN IN GREECE. (a)

BY MAJOR RONALD ROSS, C.B., F.R.C.S.,
Professor of Tropical Medicine, University of Liverpool.

PROFESSOR ROSS said the question of malaria in Greece was a subject which the Liverpool School would, he thought, take up with that keenness it had shown in connection with malaria in other parts of the world. At the beginning of the year the Lake Copais Company asked that someone should be sent out from this country to deal with the question of malaria in Greece, and he (the speaker) was sent. He went there last May, and studied malaria in the region of Lake Copais. He found the conditions were very serious. The country of Greece was a small one, about the size of the Highlands, but it was there that civilisation began, and from the Acropolis one could see the birthplace of many a movement which had benefited humanity. Therefore, it was a country dear to everyone in Europe and America—they were practically all the children of Greece, intellectually, if not by birth. The population of the country was but 2½ millions, and it was a country of mountains with valleys in between, in which valleys the population was concentrated. In the course of his investigations in the neighbourhood of Lake Copais he visited many of the schools and found evidences of malaria in many of the children in their spleen and in their blood (by pricking their fingers); the disease was very much in evidence, in fact. Out of 80 children examined at one place 38 were found to have enlargement of the spleen: in another place 13 out of 40, and in yet another 25 out of 50. In Thebes itself he only found such evidence in one out of every fifteen examined, which showed a great degree of malaria. He found the parasite in children with the greatest ease, and it was pitiable to see so many weakly children from this cause. Out of the population of 2½ millions there were last year, when there was an epidemic, no fewer than 960,000 cases—nearly one million—while the deaths numbered nearly 6,000. On an average there were, roughly speaking, last year one in every five persons who suffered from the disease. They would, therefore, see how serious was the case of Greece. The deaths were about one in 410 persons last year In this country, where children suffered greatly from measles and scarlatina, they had no conception of the state of affairs in Greece, for, whereas a child usually had the measles only once, a child in Greece might have malaria not once, but twenty times, and suffer week after week, and month after month. This would give some idea of the mischief done by this disease in these beautiful valleys. Speaking from his experience in many parts of the world, he said that malaria was a terrible scourge in any country. Italy had suffered very greatly from malaria, but in the Campagna much good had been done by the adoption of anti-malarial measures. In Greece rural life was almost smothered out, and the country had long suffered. He thought the disease was brought into the country about the time of Pericles, when the conquering Greeks brought home captives from Asia, and he would not be surprised if it were found that the spread of the disease had not a very great deal to do with checking the progress of Greece. Disease might also be found to have much more to do with the decay of other nations than they imagined—it might be the reason that the civilisation of Greece had fallen behind at a certain epoch. Malaria was first studied in Greece 2,000 years ago, and the fact that mosquitoes carried the disease was the outcome of the researches of scientific men during this long period. Therefore, they owed it to Greece to try to do something to help in the

(a) Short abstract of address delivered in Liverpool, September 17th, 1906.

extirpation of malaria there. The Anti-Malaria Society of Greece had attempted to grapple with this question in the one-and-a-half years it had been founded. They owed its inception to Dr. Savas, but the amount of money they had got was not sufficient to enable them to push the work with vigour. They had, however, ascertained the extent of the disease, and had mapped the country in which it occurred and where mosquitoes bred. They had issued pamphlets warning the people against the mosquito, which carried the disease. It was now the duty, he considered, of the Government of the country to drain the areas where the mosquito bred, and the Society would bring this fact under the notice of the Government.

THE OUT-PATIENTS' ROOM.

ROYAL EAR HOSPITAL.

Usefulness of Ossiculectomy.

By Macleod Yearsley, F.R.C.S.

A woman, æt. 34, reported herself some 18 months after operation. The history of the case was as follows:—For about 4 years she had suffered from recurrent attacks of pain and discharge in the right ear, with slight deafness, the first onset being due to "cold." The discharge had been permanent before relief was sought. When first seen, a large posterior perforation was present in the right tympanic membrane, with fœtid discharge. The hearing for the acoumeter was 16 inches. On cleansing the ear, a small superior posterior granulation was found and removed. In spite of the use of hydrogen peroxide drops, followed by antiseptic syringing, and, later, of strong rectified spirit instillations, the discharge persisted, and the granulation recurred. It was then decided to remove the remains of the drum and ossicles, together with the outer attic wall. This was done in February, 1905, when the head of the malleus and body of the incus were found to be carious, a small granulation springing from the latter close to the origin of the long (articular) process.

The case now showed a perfectly dry ear, the promontory showing as a glistening white prominence, and the head of the stapes being easily seen. Hearing was improved for the acoumeter to 40 inches, and there had been no recurrence of discharge.

Mr. Macleod Yearsley said that this case was an excellent instance of the usefulness of ossiculectomy in certain cases of chronic middle ear suppuration. It had, in all probability, saved the patient the tedium and pain of the radical mastoid operation. There were several instructive points about the case, and these he wished to take in order.

First, the presence of granulations in a suppurating ear always meant one of two things (putting aside, of course, malignant disease, which was not of very common occurrence in the ear)—either neglect or caries. In the former case, the removal of the granulation or granulations, and the establishment of proper treatment, speedily resulted in cessation of the discharge. When, however, the granulations were the result of caries, relief was less easily obtained. With regard to the part of the ear in which caries was most frequent, Mr. Yearsley said that it was probably most likely to occur in the ossicles. In reference to perforations in general, and those associated with caries in particular, he pointed out that in perforations involving the anterior or inferior segments of the membrane, ossicular caries was not usual, save occasionally in the tip of the malleolar manubrium. It was in perforations situated in Shrapnell's membrane, or in the posterior superior quadrant of the membrana tensa, that one had to look out for caries of the ossicles. The very nature of the anatomical arrangement in the attic anr the pouches behind the membrana flaccida, or membrane of Shrapnell, favoured the occurrence of caries in the head of the malleus or body of the incus.

When the perforation was one situated in the superior posterior part of the membrana tensa, the caries was generally in the articular (long) process of the incus, close to where it joined the body of that ossicle.

Of the three ossicles, caries was most common in the incus. This was due to the anatomical arrangements. Both the stapes and malleus had a blood supply independent of that obtained from the mucous membrane reflected over them. The stapes, being articulated with the fenestra ovale, was supplied by the stapedial artery and the blood supply of the inner tympanic wall. Caries of this bone was very uncommon. The malleus, having its handle ensheathed in the membrane, received blood from the vessels of that structure. Caries of its head was, however, common, on account of the anatomical arrangement of the attic.

The stapes was simply slung, as it were, between the other two ossicles. It depended for its blood supply almost entirely upon its muco-periosteum. Inflammatory swelling of the tympanum easily caused an interference with this blood supply, and, consequently, caries of the incus was common.

Mr. Yearsley next spoke of the effect of ossicular caries upon the hearing. When the amount of caries was very limited in character, its mechanical effect upon the movements of the ossicular chains, he said, was small; but when the caries was extensive, or implicated the malleo-incudal articulation, the carious bone acted as a foreign body—as a broken link in the chain, so to speak—and hearing was much interfered with. It was then that a careful ossiculectomy, which left the head of the stapes free in the tympanic cavity, gave improved hearing. Indeed, in some cases of post-suppurative deafness, in which the ossicles were bound down by adhesions, and the free movement of the stapes was consequently interfered with, removal of the ossicles gave gratifying results. In the case under observation, it would be noticed that the hearing for the acoumeter had been improved from 16 inches to 40 inches by the operation. Corresponding improvement for conversation had occurred.

But there was another point to be noted—and a very important one—in connection with ossicular caries. The focus of disease was perilously near the mastoid autrum, and mastoid disease by extension was certain to occur sooner or later. Hence ablation of the ossicles removed this dangerous proximity of a disease focus, and often prevented mastoiditis. In many cases, unfortunately, relief was sought too late to effect this prevention. The present case was one of the fortunate ones.

Finally, Mr. Yearsley said a word as to the operation of ossiculectomy itself. It consisted in the removal of the malleus and incus. The stapes remained. This removal aimed at the ablation of the disease focus (viz., the carious ossicles) and proper drainage. It must be remembered that the latter could only be ensured by the removal of the bony outer attic wall as well. If this were not done, failure was inevitable and disappointment sure.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Case of Laceration of the Thorax.—Mr. Peyton Beale operated on a boy, æt. about 5, who had been brought to the hospital in the following condition—having fallen out of a window upon some iron spiked railings a few minutes previously. (1.) All the soft parts of the right arm, with the exception of part of the triceps muscle with the skin over it, were torn through, the lacerated wound extending from the insertion of the deltoid to just above the elbow. The extent of the laceration was shown by the fact that at least six inches of the media and ulnar nerves were hanging from the wound. (2) There was a lacerated wound

of the left thorax which started from the lower costal margin, extending upwards through the cartilages and the ribs to the third rib; the laceration was so great that the wound would admit of the insertion of the entire hand; the pericardium was fully exposed to view, the lung was collapsed and lying at the back of the thorax, though a portion of it was projecting into the wound; one could put one's hand into the wound and grasp the whole of the heart. The boy had several fractures of the skull; the whole of the back of the cranium was freely movable laterally and there was hardly any portion of the cranium where bony crepitus could not be elicited on pressure. A little chloroform was administered, and the house surgeon, Mr. Grell, dealt with the right arm, ligaturing the ends of the brachial artery and rapidly suturing the skin edges, leaving apertures for drainage. Mr. Beale approximated as far as was possible the torn costal cartilages with thick catgut sutures and removed several pieces of rib from the wound; he then sutured the skin, putting in a gauze drain and applying a large dressing, so as to exclude air as far as possible from the pleural cavity. He then made a free incision in the scalp, but as there was no evidence of any pieces of depressed cranium, and as there was but very little hæmorrhage from beneath the cranium, he did nothing further.

The boy was, of course, considerably collapsed, and was immediately put to bed with several hot bottles. A few hours later Mr. Beale gave him copious injections of hot salt solution into the rectum; the patient improved rapidly, and was well enough to ask for food within twenty-four hours. Thirty-six hours after admission he was alive and doing well. Mr. Beale subsequently said that if the boy recovered he should make an attempt to unite the severed nerves and muscles of the arm by removing two or three inches from the middle of the humerus and so shortening the limb.

NORTH-WEST LONDON HOSPITAL.

AMPUTATION OF THE HAND.—MR. TEMPLETON operated on a man, æt. 50, who had been admitted as an emergency for an accident to the left hand inflicted by a chaff-cutting machine. The hand was completely severed from the limb; the section, which was perfectly clean and defined, and which had passed through bone, arteries, nerves, &c., on the same plane, had a direction upwards and outwards towards the radial aspect; the osseous structures exposed consisted of varying lengths of the metacarpus, some two inches of the fifth metacarpal bone and the base of the first only being left. On admission the patient had received first aid in the casualty department from the resident medical officer, Mr. Binns, who tied several bleeding vessels. The man was admitted into the ward, and shortly afterwards seen by Mr. Templeton, who proceeded to operate in order to secure a satisfactory stump. His object in this respect was, he said, to preserve as much of the limb as possible and to retain the carpal bones. The absence of any laceration of the soft parts was, he pointed out, of very material assistance towards this end. A tourniquet had been previously applied. The forearm was shaved, thoroughly scrubbed with ether soap and biniodide spirit, and completely immersed in 1 in 1,000 perchloride of mercury lotion, whilst all the clots were cleared away. The bases of the metacarpal bones were carefully dissected, the tendons and nerves resected, and all the visible vessels secured. The margin of the skin was then cautiously trimmed. The result of these proceedings was a satisfactory flap which could be turned outwards and which could completely cover the exposed distal row of the carpus. Prior to suturing the flap in position, the head of the os magnum and the posterior margin of the trapezium were removed by bone forceps. The object of this, Mr. Templeton pointed out, was to impart a rounded rather than an angular character to the stump. The tourniquet was now taken off, and the wound entirely stitched up with silkworm gut; sterilised dressings were applied and an angular splint fixed to the arm and forearm. As the patient was rather collapsed through loss of blood before admission, ether was adminstered to produce anæsthesia. Mr. Templeton remarked that had the case been one of crushing the operation he had done would not have been possible; the clean section had inflicted very little damage to the parts adjacent to the wound, therefore he had felt justified in preserving the skin in its entirety. The very small amount of skin removed by clipping with scissors was only in order to secure complete apposition when the wound was subsequently stitched up. Had the hand been torn away, nothing short of amputation through the forearm would have secured a satisfactory healing. The tourniquet, he said, had been put on before the cleansing of the limb, as this latter process very often starts fresh hæmorrhage; the instrument was also left during the operation as a precautionary measure.

The subsequent progress of the case justified the expectation that satisfactory union would occur in the flaps. No sloughing took place, and the flaps joined by first intention. Movement of the carpus was obtainable in a fortnight, and Mr. Templeton hoped this movement would increase the usefulness of any appliance.

CORRESPONDENCE.

FRANCE.

Paris, Sept. 23rd, 1906.

TREATMENT OF TUBERCULOUS GLANDS.

DR. CALOT, the celebrated orthopædic surgeon, has contributed an article to the *Journal des Practiciens* which is well worth reproducing. In presence of tuberculous suppuration, there are three methods of treatment—operation, abstention, puncture followed by injections.

The Value of Operations.—Without doubt, operation can claim a large number of cures where it was performed on cervical adenitis and tuberculosis of the limbs. Yet it must be remembered that the fact of large ablations does not constitute an absolute guarantee of cure, for healthy tissues may be inoculated during the operation, so that the most complete operations are followed frequently by fistulæ. Fistula is the rule in case of tuberculosis of the bones, the joints, and especially in Pott's disease, where it is never possible to make a complete operation. Many surgeons seem not to understand the harm they do in transforming coxalgia, or Pott's disease, closed, into coxalgia, or Pott's disease, open. Closed, Pott's disease has 99 chances out of 100 to get well; open, the proportion is the same, but reversed—it has 99 chances out of 100 of terminating fatally sooner or later. That is what a surgeon does who lightly opens an abscess by congestion. By the resulting fistulæ septic germs penetrate, provoking infection, fever, septic absorption, and consequent degeneration of the liver and kidneys.

and death at the end of one or more years. Such is the constant result of operations for Pott's disease. It is true the situation is different in case of superficial tuberculosis, cervical adenitis, idiopathic cold abscess, spina ventosa, osteitis of easy access, but there is always danger of infecting the healthy tissues in the course of the operation, as we have already said.

A celebrated surgeon at Paris removed a tuberculous testicle from a child æt. 13. Shortly after the operation (three months) the disease attacked the right hip joint, and two months afterwards the left hip. Hundreds of similar cases might be mentioned showing the risk of tuberculous inoculation from operation.

But where the operation is really successful, at what price is it obtained? Mutilation. Let us take a case of cervical adenitis. The operation has been in every way successful; septic infection and tuberculous inoculation have been avoided, and reunion by first intention has been obtained; but is it of small importance that (in case of a young girl) the patient bears an ugly cicatrix which to the end of her days will cause her infinite moral trouble, lessening her chances to be settled in life? Not to speak of young ladies, how many clerks and domestics are heavily handicapped by large, unsightly cicatrices which frequently hinder them from earning their bread? The following aphorism should be borne in mind in external tuberculosis: the bistoury rarely cures, frequently aggravates, and always mutilates.

Abstention.—Systematic abstention is preferable to a bloody operation. I am not alone in this opinion. A professor of the Paris faculty was wont to say that, in presence of surgical tuberculosis, it was better to fold one's arms than to take up a bistoury. I heard almost the same said at the Orthopædic Institution of Milan, where a surgeon said to me, "Formerly we opened and curetted all abscesses of coxalgia and Pott's disease; now we never touch them, and the patients do much better. If not touched, here is what happens: A large number of tuberculous abscesses become absorbed, and this is not only true of superficial abscesses, but also and particularly in those of Pott's disease, if the patient is enjoined to absolute rest and receives a good general treatment.

The remainder open spontaneously, but the risk of inoculation is infinitely less than when they are opened by the knife and curetted, while that of secondary septic infection is also less than where fistula succeeds surgical interference. That is why the fistulæ which are observed in neglected country children get well much oftener than those following the most scientific operation, and mutilation is less apparent after spontaneous rupture.

Puncture and Injections.—I hasten to say, however, that we have something better than abstention for the treatment of tuberculous abscesses. If we sin by commission in operating, we can sin by omission in leaving the abscess to open of itself. We should not only not operate nor open a tuberculous abscess, but also prevent them from opening spontaneously by puncturing them with a fine trocar, by which we obviate the risk of mutilation, septic infection, and inoculation. On the other hand, if we take advantage of the presence of the cavity of the abscess by replacing the pus by some modifying liquid which will rapidly heal the tuberculous walls, we will have satisfied the most fastidious. The cure will thus be obtained without any danger and without mutilation.

Such is the ideal treatment, and it is not a myth, but an agreeable reality.

Puncture followed by injections not only cures 99 times out of 100 without risk or deformity, but is simple and easy to execute by every medical man.

Every practitioner can obtain this successful result, provided he follows exactly the modus operandi we advise.

The instruments required are only three in number: Colin's trocar No. 4, a small aspirator, a syringe adapting to the trocar and easily sterilizable.

The operator begins by evacuating the collection by means of the aspirator adapted to the trocar, and immediately replacing the pus by an injection of one or two drachms of one or other of the following liquids:—

Olive oil	1½ ounces.
Ether	1½ ounces.
Creosote	40 drops.
Iodoform	1 drachm.
Camphorated naphtol ...	1 drachm.
Glycerine	1 ounce.

If the abscess is very ripe, the former should be employed; if only partially so, the latter. About ten injections are necessary to obtain a cure, leaving five days between each. The abscess might be aspirated every two days if necessary, and the puncture should be made in a different place each time, so as not to injure the skin, and in no instance should the needle be inserted into a point where the skin seems ready to break. Although the pus may be evacuated every two days, the injections of the modifying liquid should not be made oftener than every five or six days, and no more than ten should be given, after which compression by cotton wool and a Velpeau bandage should be made over the abscess so as to bring the walls together as exactly as possible.

GERMANY.

Berlin, Sept. 23rd, 1906.

Stasis Hyperæmia in Ophthalmology.

R. Hesse, Graz., has a paper on this subject in the *Zbl. f. Prakt. Augenheilk.* The subject had already been mentioned in an earlier number of the journal by Renner, who produced the stasis hyperæmia by means of a rubber bandage applied round the neck, but Hesse, on account of the considerable unpleasantness of such a method, employed suction.

He made use of a kind of cupping glass made to fit the part to which it was pressed, and to this was attached on indiarubber tube and at the end of this a ball.

The action took place with a different pressure of 20 to 50 mm. of mercury, with 100 mm. hæmorrhage took place from the conjunctiva. If the apparatus was applied with the eyelids closed the action was mainly on them. In five minutes they became red and swollen, in half an honr they were blue coloured and œdematous, the edges of the lids becoming slightly everted. If the eyelids could not be closed the action was quite different. The connective tissue of the lids became injected and swollen, they became sometimes quite inverted, so that the conjunctival tissue itself came under the influence of the suction. Dilatation of vessels first took place at the bulbar conjunctiva, then serous fluid collected under it, and after half an hour's action pressed forward to the corneal margin and showed the appearance of a marked chemosis. The cornea itself does not escape change. Here also the influence of increased fluid is noticeable; it appears œdematous and slightly dull on the surface. No action of the iris was noticed in the human subject, but it had been in rabbits. The anterior ciliary vessels were also affected. The deeper parts of the eye were not affected, neither was the intra-ocular pressure.

He had also used suction in pathological conditions. In pannus eczematosus he found more filling of the vessels and softening of the tissues from fluid. In keratitis parenchymatosa an exhaust action of thirty minutes caused a marked influx of blood.

In order to show the action on the ciliary vascular system, a solution of fluorescine was injected subcutaneously, and then the left eye brought under the action of an exhaust. After three-quarters of an hour there was distinct green colouring of the fluid of the chamber and of the cornea of the eye affected, whilst no trace was seen in the other eye even after an hour.

Stasishyperæmia, according to the author, may be employed in phlegmous furuncles of the lids indacryocystitis, all inflammation affections of the eyelids, the conjunctiva and cornea, and especially conjunctivitis eczematosa and trachoma.

As regarded chronic blennorrhœa of the tear sac, iritis, and cystitis, more observation is required. Lastly, the author gives the history of a case of suppurative ulcer of the cornea that had been treated in many ways, including cauterization, atropine, iodo

form subconjunctival injection of saline fluid, moist warm applications, and in spite of all steadily advanced. As soon as ever the hyperæmia was established, the pain ceased, the advancing margin of the ulcer disappeared, the hypopion was absorbed. As the treatment was omitted one day the ulcer started again, but fresh and more continued application of the exhauster or sucker brought about a complete cure.

PURULENT INFLAMMATION OF THE MOUTH CAUSED BY THE TELEPHONE.

A writer in the *Zeitsch. f. Med. Beamte*, Dr. Bunde relates a curious case of the above. A farmer who had been ill with stomatitis a fortnight and had been treated with nitrate of silver and mouth washes of chlorate of potash, came under treatment. There were swelling and softening and a blue-red colouration of all the gums, with tendency to bleeding, pasty covering over the edges of the gums, ulcers on the margin of the tongue and hard palate on the lips, and buccal mucous membrane, fœtor, and salivativa. Etiology was at first absolutely dark. The treatment consisted in alum water and peroxyde of hydrogen and painting with tinctures of rhatany and myrrh. There was improvement at first, but on a tooth being extracted everything got worse. It was several weeks before recovery took place.

Whilst this patient was under treatment, a second came, a post official, who presented similar symptoms, but not quite so bad. Now the etiology became clear. The second had had to test the telephone apparatus of the first at the time when he was ill; his mouth also was close to the mouthpiece, as the apparatus was working badly.

The post office was communicated with, and the authorities promised to make arrangement for the prevention of such occurrences for the future, *i.e.*, they would issue instructions that in speaking the mouth should never be brought into contact with the receiver of the instruments. The report does not state when contact between the receiver and the lips or even moustache of the speaker is considered necessary, or rather was considered necessary previous to his warning communication.

AUSTRIA.

Vienna, Sept. 23rd, 1906.

SERUM IN CROUPOUS PNEUMONIA.

TAUBER reviewed his treatment with Romer's pneumococci serum in cases of croupous pneumonia, in the "Allgemine Krankenhause," and expresses himself satisfied with the results. The serum is prepared by Merck of Darmstadt, from horse, cattle and sheep which are inoculated directly from the human subject. The serum is described as bactericidal and polyvalent. The dose commences with 10 c.c., increasing to 30 c.c. injected into the muscles. No local or serum exanthema are to be observed.

Of the 46 cases treated last year with the serum, nine were very severe. diplococci pneumonia, and five croupous pneumonia, with different excitants. The serum had very little influence over the latter cases. This can also be said of one case of caseous pneumonia with advanced tuberculosis, as well as a confluent lobular diplococcus pneumonic case, æt. 61, suffering from chronic tuberculosis. Of the first nine cases, seven of them had the temperature reduced to normal within ten to fifteen hours after the first injection. In the case of a drinker with right lung inflammation, 30 c.c. were injected in the evening; in the morning, or thirteen hours after the injection, the temperature was down, but the pulse steady at the same as the night before. By midday, the temperature rose again to 38.2 C., but in the evening it again fell and remained low ever after. In every case the subjective symptoms were greatly improved, the patients expressing themselves greatly relieved. Tubercular cases do not appear to be influenced beyond the subjective symptoms.

HYDROCEPHALUS.

Fuchs next showed an athlete, æt. 25, who had all the symptoms of micromelia. He appeared as a caricature of normal body and very short extremities. The Röntgen Rays showed a very low development of the epiphyses with distortion and contraction of the diaphyses of the long bones. The thyroid and genitals were normal, but the intelligence low.

TORSION OF THE HEAD.

Fischl showed a very interesting case for the anatomist of a young man who is engaged in variety work on the stage. From long practice he was able to turn his head 180° on the body, or, in other words, he could turn his face directly backwards. As might be expected the muscles in their natural position could not place the head in this diametrically opposed position, but with the assistance of the hands and the lax condition of the ligaments around the atlanto-epistropheal joint he could smartly place his head in a posterior attitude. This distorted position could not long be sustained, owing to the danger of suffocation from the stretching and distortion of the trachea. Notwithstanding this abnormal twisting of the head on the body, the lateral movements were normal. Fischl pointed out that the anatomy of atlanta joint required no abnormal bony change to produce the movement, as the freedom of the ligaments was all that was required, which had been unduly stretched by long and continuous straining.

CHILDREN'S HOSPITAL.

A new annex to the "Franz Joseph Spital" has just been opened by the Emperor himself, with great *eclat* and demonstration. This portion, "H" and "I" divisions, are built with the latest scientific improvements, and embellished in the most artistic fashion. "H" is devoted to tubercular and scrofulous children, while "I" is for general ailments, with "boxes" for mother and child or children, as some of them are fitted for three children with mother. "I" has also a fine "Couveuse," or incubator, so that the embryo can now be incubated without the assistance of the female!

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

THE PUBLIC HEALTH QUESTION.—The health of the city, and the steps which ought to be taken to improve it, continue to be the general topic of conversation in Belfast, and matters seem to be approaching a crisis. As was reported in this column last week, the Corporation decided, in spite of all opposition, to offer only £600 per annum for a Medical Officer of Health, though they give their Coroner £550 and allow him to take private practice also! It is recognised on all sides that the object in view is to prevent any really good outsider from applying, and to appoint a local general practitioner, lately a member of the Corporation. There is a strong and growing feeling that the intense keenness of the City Fathers to perpetrate such a very gross job in the face of strong opposition is by no means entirely due to their friendly feeling to their late colleague, but is at least partly due to fear of what a good independent medical man might do in the way of throwing light on the dark places of the city, slums and jerry-built houses, in which the members of the Corporation are largely interested. An interesting proposal has been made, and we earnestly hope it may be carried out, and that is to make out a list of all members of the Corporation who are interested in house property or building (as many of them are known to be), and publish it with a parallel list of those who have steadily voted against getting a thoroughly qualified Medical Officer of Health. A medical member of the Corporation has assured your correspondent that the result would be very striking.

Meantime, the advertisements for the post have been published, but they were sent to certain medical journals timed to appear on September 22nd, the day on which applications were to be sent in! When attention was called to this in the Press, it was explained

that notices of the vacancy had been sent direct to the Public Health Officers of many English and Scotch towns, but only a week before applications had to be sent in. The whole business is an exceedingly disgraceful one, and the Citizens' Association has done well in calling a public meeting for Thursday, the 27th, to consider what steps can be taken to mend matters. One suggestion is that a Royal Commission be asked for, to inquire into the health of the city, and the reasons for its deplorable state. No doubt strenuous efforts will be made by the property owners to prevent such a disaster as this would be to them.

LETTERS TO THE EDITOR.

SANITARY ADMINISTRATION.

To the Editor of the Medical Press and Circular.

Sir,—In the *Times* of Saturday last appeared a leading article based upon the Local Government Board's Medical Report for 1904-5. The article, by an able writer, is one of a kind familiar to readers of the leading journal. These articles really constitute a reiterated indictment of local governing bodies. They reiterate in slightly varied terms the statement that if those bodies could be made to carry out the laws with the administration of which they are entrusted, the mortality throughout the country could be reduced by one-half. The *Times* asks what is the use of establishing societies for the promotion of bodily vigour whilst the gross fundamental abuses it describes are allowed to continue—abuses which form the prime cause of physical deterioration among that section of the people from whom the best stock should be produced. Sanitary administration is at its worst in the smaller "urban" districts inhabited by what are really rural populations. When it comes to the suggestion of remedies, the *Times* does not lead us much further. It is useless to talk of giving fixity of tenure to Medical Officers of Health whilst many authorities either refuse to employ such an officer or else pay and engage him to give a totally inadequate portion of his time to perform his duties. Not much more practical is it to suggest that increased powers of coercion over authorities should be conferred upon the Local Government Board. This would need new legislation, and would be an interference with democratic methods and institutions. The real hope of reform lies in the improvement in the quality of the authorities. This can be brought about only by the rousing of public spirit and local patriotism. So long as the better class stand aloof, and allow themselves to be represented by ignorant and selfish men, so long will the existing evils continue. These evils are detrimental not only to the parish in which they prevail, but they also inflict deadly injury upon the nation, which is merely the sum of the units into which, for convenience of government, it is divided.

I am, Sir, yours truly,

M. O. H.

DANGER OF TEA DRINKING.

To the Editor of The Medical Press and Circular.

Sir,—In my rather wide experience I have continually met patients who have been debarred tea. As a very general rule, I restore the use of the tea to the great comfort of the patient.

"Affirmative Instances"—*i.e.*, concluding from a "few times hitting," and ignoring the "many times missing"—Bacon tells us, are "the roots of all superstition." Remembering this caution in method, I may yet say that I have drunk tea after dinner for thirty-five years, with great comfort to myself. My father lived to 87 years, and always had his cup of tea after dinner for 70 years. He was a total abstainer from alcohol.

Look at the labourer digging up the gaspipes or sewers of our streets. He eats his cold bit of meat or cheese and bread, but enjoys the drink of hot tea after his frugal meal.

See the Australian shepherd or bushman, with his rather tough damper; he enjoys his pannikin of hot tea after his meal. The Canadian lumbermen, the Mongolians, the Tartars, the Russians, the Chinese, all enjoy their tea. I never knew an Australian bushman or Canadian, or John Chinaman blame the use of tea.

I fear that if I gave up my after-dinner tea, I should long for claret or cold spirit and water!

There are pernicious fashions in medical practice; let us guide our patients into the rational use of tea, &c., and not debar their right use. One highly fashionable West-end physician debars "genteel" lady patients the use of "raw" fruit—an astounding folly in my opinion! I have eaten fruit freely all my life, with natives of Australia, India, South Africa, West Indies, &c., and I have known only good from such custom. One cannot sufficiently express one's repugnance at the fashionable physician hindering the use of fruits, potatoes, &c., to *parvenue* ladies, who are told that they are "too delicate to digest raw fruits"! The contrast and wisdom are seen in the West Indies, where the negro rejoices in munching a long stem of raw sugar-cane; and in the East Indies, where the wise and highly civilized native rejoices in the use of the lime, or tamarind, or mango, &c.

Forty and more years ago, when I was in charge of natives of India, I introduced the use of tea, and to the great satisfaction of the people. I formed the opinion then that some such "aromatic" molecule as tea, coffee, &c., was greatly needed in their too sparse diet.

Tea may, if taken soon after a meal, check the flow of gastric juice, but so will a glass of grog; none the less, the tea and the grog will light up and set free potential into kinetic "energies" and motions, which will counteract the little temporary check in gastric secretion. What we hypothetically call "the vital" is set going by the stimulant; a bare present chemistry is no measure of the (hypothetical) "vital."

I am, Sir, yours truly,

Abdool Raheem, M.D.

MOTOR-CARS AND DUST.

To the Editor of the Medical Press and Circular.

Sir,—My absence in Canada, attending what proved to be a very successful meeting of the British Medical Association, prevented my noticing at an earlier date Dr. Wilson's answer (1) to my recent letter on Motor-Cars and Dust (2). This reference to Canada suggests the passing remark that at Toronto quite a common and agreeable sight was afforded by young ladies—girls, in fact—driving their own motors.

I think I am justified in expressing the opinion that Dr. Wilson's comments scarcely succeed in meeting my main objection. I insist upon the fact—and I am glad to find that you can partly agree with me—that the motor-car, and especially the car provided with pneumatic tyres, cannot create dust in any appreciable quantity. That it distributes dust—largely produced, let us remember, by the horse—is quite another question. I can even perfectly understand that "within the last year or two special legislation has been found necessary to control the origin of this dust, and that people living in main roads most traversed by motor-cars are giving up their houses and removing to side streets not patronised by the modern Jehu." This is no more than what should be expected.

But such facts are not a sufficient reason for condemning the motor-car, unless, indeed, we are prepared to denounce the railway and the steamboat. The motor is a factor of considerable importance—and this importance can only grow—in our modern social development. Every progressive community will encourage its use, for every such community will understand that material and even intellectual progress are closely connected with improved facilities of communication.

We perhaps do not grasp all the conditions of the problem. We may not always remember, for instance, that for one person who travelled a century ago there

(1) Med. Press and Circ., Aug. 8th. (2) Aug. 1st.

are ten or a hundred travelling to-day. Who dreams of giving the avenues of a modern city the dimensions of mediæval streets and alleys? It is not reasonable to expect our present thoroughfares to meet all the requirements of incessantly increasing traffic. Why not create special highways for the motor?

This is what must soon be contemplated as a necessity for the Riviera, where the Villefranche road is being already widened. For the evil pointed out by Dr. Wilson could scarcely be exaggerated. The prevalence of dust is indeed a cause of general complaint both amongst our residents and visitors. But "Nice, with the other beautiful health resorts," and the hotelkeepers in particular, will endure a good deal of "ruining" so long as the motorist is not unjustly discouraged.

There is one last point in favour of the motor-car that I would not like to omit. Its rapid adoption as a substitute for the omnibus drawn by horses in the streets of London will, it is to be hoped, discourage the development of the tramway. Anything more unpleasant, I am sure most of your readers will allow, than the incessant din of the unsightly American road-car could scarcely be imagined. And this is not the only or even the chief objection to be urged against it.

I am, Sir, yours truly,
A. W. GILCHRIST, M.D.

Nice, September 23rd, 1906.

DISTRIBUTION OF HONOURS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I trust that you will grant me the hospitality of your columns to ventilate a personal grievance under which I have been suffering for many years. You, sir, and your readers are doubtless aware of the scanty way in which decorations for distinguished services are awarded by the Indian Government to medical officers. I think my own case illustrates this hardship so forcibly that I venture to send you a *resume* of my services, and to ask if you think I have been fairly treated. In forming a judgment on the merits of the case, I would beg of you to remember that it has been my lot to see a number of medical officers with far less experience and war-service than I, presented with honours and decorations of various kinds, and while I have nothing to say against their abilities and deserts, I must say that I think my name should have been included among them. The majority of military officers who served during the memorable Mutiny at the same time that I did have been decorated with high honours.

As to my own case, I may say that it is fifty-three years since I first sailed for India, and that soon after landing I saw active service in the first Meranzie Expedition. When the Mutiny broke out I was attached to the Punjab Cavalry and I acted as Brigade Major under Sir Crawford Chamberlain during the critical procedure of disarming the native troops at Mooltan; in fact, it was I who carried the message to the cavalry, to open order and expose the guns, the manœuvre on which the whole success of the undertaking depended. In the taking of Bullee, I served under Colonel Sir W.T. Hughes, and was able to lend him much assistance during that dangerous operation, and again the following day, when he was surrounded by the mutineers I managed to run the gauntlet with a party of picked men and bring up reinforcements. For this act I was specially thanked by the Commander-in-Chief. During the rest of the Mutiny I was constantly on duty, both medical and military, and was never laid up for a day. In 1860, I was in medical charge of the Guides during the Wuzuri Expedition, and when Sir Harry Lumsden's camp was surprised and rushed by the enemy during the night, I was able to rally some 200 men who had broken and bring them to relieve the others who were overwhelmed and nearly cut up by the Wuzeeries. I had an almost miraculous escape from being killed myself, and my name was specially mentioned by Sir Harry Lumsden for the help I afforded him. I held many responsible medical posts in India. I was in joint charge of Simla during the cholera outbreak of 1866-67, when I received the thanks of the Lieutenant-Governor of the Punjab; I was sanitary officer to the great Durbar of '76, when the Queen was proclaimed Empress of India; and I was in charge of the Dinapore Dispensary and Dera Ismali Khan Dispensary, from both of which places I received special acknowledgements for my success in operating for stones and cataract, and in stamping out the cholera epidemic of '73-'74. In fact, so well known was I to the frontier tribes that when I was at the latter place I was invited to go to Cabul to practise. I also invented the "Tuson" helmet for the protection of troops in tropical countries. I must not take up more of your space with the details of my career, but I think, sir, you will agree that many less arduous and important ones have received substantial recognition from the Indian Government.

I am, Sir, yours truly,
JOHN E. TUSON, M.D., F.R.C.S.

Eastbourne, Sept. 7th, 1906.

FOREIGN *VERSUS* ENGLISH SPAS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I was somewhat amused at your "light and breezy" reference to foreign and English Spas last week, under the heading of "The Marienbad Cure," and the motives and habits of certain of the British public who yearly frequent the Continental health resorts, instead of those at home. It is, of course, ridiculous, as you remark, to imagine that the waters possessing similar medicinal qualities in this country would be less effective when administered here than abroad; but habit and fashion govern most things in this world where money is concerned, and I fear we must admit complicity to a certain extent in this diversion. We send our patients to the Spas of France, Germany, or Austria, but do we ever hear that our *confrères* in those countries send their patients to English Spas? During my annual holiday this summer I happened to be in the Peak district of Derbyshire. I had read of its natural beauties, but knew nothing personally of them; judge my surprise when passing through the Derwent Valley to find at Matlock Bath a large hotel fully equipped with every bath appliance one could meet with at Marienbad, Nauheim, or Mont Dore, with its mud-baths and its natural springs, all under the control and direction of an English physician (who appears to have studied the Continental systems), amid natural scenery unapproached by anything I have seen abroad. Yet I must perforce admit that I was unaware up to a few weeks since that such a Spa existed. I, of course, knew a little of Matlock, the "Metropolis of Hydropathy," where there is no Spa or natural spring; but of Matlock Bath and its up-to-date bathing establishment attached to the Royal Hotel, I was ignorant, and it occurred to me what a delightful spot this would be for the invalid as a winter resort, surrounded as it is with the High Tor and other peaks clad with conifers, larches, and evergreens, and protected from north and east winds. Yet our patients often undergo the discomforts and expenses of long journeys abroad, which could easily be avoided did we take the trouble to visit our Spas at home, and find out for ourselves their suitability in certain cases which we now send elsewhere.

I am, Sir, yours truly,
M.A., M.B., CANTAB.

London, Sept. 19th, 1906.

DURING the year 1905 two "professional" deaths occurred amongst old St. Mary's Hospital men, namely, that of Mr. Harold Hand, from *post-mortem* septicæmia at the Norfolk and Lynn Hospital, and that of a brilliant Army officer, Lieutenant A. F. Tulloch, who died of sleeping sickness contracted on an expedition in East Africa.

OBITUARY.

ANDREW M. L. RATTRAY, M.D.

On September 18th the death occurred of Dr. Andrew Rattray, Portobello's oldest medical practitioner. He was educated at Edinburgh University, where he took his M.D. degree in 1862. Dr. Rattray served on the Portobello School Board till its functions were taken up by Edinburgh School Board. He took much interest in the movement to suppress cigarette smoking by the young. He is survived by his widow and three sons and one daughter, two sons being medical men and the third an Army officer.

THOMAS LUCAS, M.R.C.S., L.S.A.

Mr. Thomas Lucas, of Cambridge, died suddenly on September 20th. Educated at Middlesex Hospital, he took the diplomas of M.R.C.S. and L.S.A. in 1863. He went into practice at Cambridge, where he soon achieved great popularity. He had a large clientèle among undergraduates, to whom he acted as mentor in other matters besides medicine. He took great interest in the University hunt and the Polo Club, and was for a number of years judge at the University steeplechases at Cottenham.

JOHN GILMOUR KERR, M.B., C.M.

Great regret is felt at Cumnock at the death of Dr. J. G. Kerr, which took place on September 17th, after a long illness. He was only in the fortieth year of his age. A native of the parish of Neilston, he took the medical classes at the University of Glasgow, and soon became a medical practitioner when but little more than twenty-one, and seventeen years ago he went to Cumnock as assistant to the late Dr. Lawrance. On the death of Dr. Lawrance some twelve years ago, he succeeded to the whole of the large practice, being doctor for the large ironworks of Messrs. William Baird and Co. at Lugar, and also for the parochial board of the parish. Dr. Kerr was a Justice of the Peace for the county, and both as a doctor and a gentleman he was highly trusted and beloved. He leaves a widow and one daughter of tender years.

DAVID HENRY GOODSALL, F.R.C.S.

Mr. David Henry Goodsall died suddenly from heart failure at his residence, 17, Devonshire Place, W., on September 14th. He received his professional education at St. Bartholomew's Hospital. In 1868 he became a member of the Royal College of Surgeons, England. After holding a resident appointment at his own hospital, he became house surgeon to St. Mark's Hospital. In 1872 he was admitted a Fellow of the Royal College of Surgeons. After holding the post of assistant surgeon to St. Mark's Hospital, he became surgeon and eventually senior surgeon, and retired from the hospital on attaining the age limit. At the time of his death he was also senior surgeon to the Metropolitan Hospital, and surgeon to St. Saviour's Hospital. He was joint author (with Mr. W. E. Miles) of "Diseases of the Anus and Rectum," and he contributed papers on the same subject to various journals. He was an able surgeon, and he obtained excellent results in the special branch to which he had devoted his energies. He was a good man of business, and held for many years, among other posts, the office of director of the Western Telegraph Company. By the Medical Society of London his loss will be severely felt, as he was for 19 years chairman of the house and finance committee and honorary treasurer since 1896.

PROF. ISIDOR VON NEUMANN, OF VIENNA.

Many a practitioner and student in this country will be grieved to learn that Prof. Neumann passed away last week rather suddenly. He was recognised as the leading authority on syphilis, to which he devoted a great part of his life. Born in Moravia, 1832, he had thus reached his 74th year at death. He took the degree of Doctor of Medicine in Vienna, 1858, and three years later was appointed assistant to the Chair of Dermatology and Syphilis, which he subsequently succeeded to in 1887 on the death of Prof. Siegmund, and which office he held till 1903, when the rules of the University demanded his retirement on the age limit. This enforced retreat from office gave him much pain, and not a little to his friends, who considered him fit and capable for the duty. Kaposi was his great rival, and, being a more ready speaker and better elocutionist, carried his audience with him, while Neumann forced his logic with humour and wit, at which he was an adept. Both have now gone, and left the Vienna school much the poorer. Neumann was an extensive writer (several of his lectures appeared in our own columns), and many of his works have been translated into other languages besides English. He had always a weakness for the latter, which fact gave the English student a higher estimate in his favour. He is reputed to be the first who classified Pemphigus Vegetans, but his name will be long remembered by his text-book on syphilis.

DR. HENRY TWEEDY, OF DUBLIN.

We regret to have to record the death, at the very advanced age of 96, of Dr. Henry Tweedy, of Rutland Square, Dublin, who was, we believe, the "Father" of the medical profession in Ireland. Dr. Tweedy obtained the licence of the Royal College of Physicians of Ireland in the year 1836, and the membership of the Royal College of Surgeons of England in the same year. In 1838 he became a Doctor of Medicine of the University of Glasgow. In his student days he was a pupil of the late Mr. Cusack at Dr. Stevens' Hospital in Dublin. For some years he acted as private medical adviser to the Duke of Manchester, and subsequently practised in Dublin. Dr. Tweedy was well known for his deep interest in the welfare of the poor, and his devotion to charitable and religious objects. His interest in the practical side of his profession was also great, and from time to time he contributed articles to the columns of this journal. Many of his relatives are well-known members of the medical profession, notably his son, Dr. H. C. Tweedy, for many years one of the physicians to Stevens' Hospital; his nephew, Dr. Hastings Tweedy, the present Master of the Rotunda Hospital; and his son-in-law, Sir William Smyly, one of the former Masters of the same institution. Up to a short time before his death the late Dr. Tweedy was conspicuous for his wonderful mental and physical activity, and, indeed, it was partly due to the latter that at the end his death occurred suddenly, as, a few days prior to it, he had a severe fall, which resulted in an intra-capsular fracture of the femur.

SPECIAL ARTICLES.

THE HEALTH OF THE ARMY.

The Report of the Army Medical Department for 1904 has recently appeared, and it contains much information of value to those interested in medical statistics. Like most Government publications its arrangement is difficult for purposes of reference, and it is no easy matter to pick out from a mass of dry-as-dust details the facts and figures of real importance. As we presume even yellow books are meant to be read, or at any rate used for reference, we have never been able to see why such volumes are not furnished with indexes.

We find that the sick admission rate and death-rate for the year represent proportions respectively of 653.1 and 6.19 per 1,000 of strength, as compared with 758.1 and 7.13 in the previous year. The principal causes of admission during the year were venereal affections, diseases of the digestive system, injuries, malarial fevers, diseases of the skin and diseases of the respiratory system. The chief causes of death were enteric fever (433), injuries (188), diseases of the digestive system (187), diseases of the respiratory system, ex-

cluding tubercle of the lung (147), and diseases of the circulatory system (121). The invaliding records show that diseases of the circulatory system (862), diseases of the digestive system (749), diseases of the nervous system (635), diseases of organs of special sense (553), and tuberculous diseases (476) head the list in the case of men finally discharged as unfit for further service. Malarial fevers, debility, enteric fever, Malta fever, and dysentery caused a great deal of invaliding from abroad, but in most of the cases, change of climate greatly benefited the health of the men and good recoveries occurred.

As regards the prevalence of particular diseases in the Army, we learn that the admission and death-rates from tuberculosis have shown a steady diminution during the past twenty years, whereas the invaliding rate has remained practically stationary. Syphilis shows some diminution in all parts of the Kingdom except Scotland, where it appears to be on the increase.

The principal operations necessitated by the various cases admitted to military hospitals in the United Kingdom during the year were more numerous than in the preceding year. Chloroform was the anæsthetic used in the majority of cases; ether was also used (222 instances) and gas (112 instances); while gas and ether, ether and chloroform, nitrous oxide and ether, cocaine, ethyl chloroform, chloroform and alcohol, eucaine, and ethyl chloride were used in a few instances.

We are glad to notice that the work of the department in dental surgery is considerable, some 50,000 men having come under treatment.

The references to research or original work by officers of the department are not considerable, though a useful note is furnished with reference to the investigation of Malta fever by Major Horrocks and his colleagues.

The figures regarding recruiting may possibly throw some light on the state of health of the classes from whom recruits mostly come. Of 70,346 recruits inspected, it appears that 24,782, or 352.29 per 1,000, were rejected after the first inspection or within three months of enlistment. The largest number of rejections on inspection was caused by defective development. Among other causes of rejection, loss or decay of many teeth was the most frequent, defective vision coming next, and then, in order, defects of the lower limbs, disease of the heart, flat feet, varicocele, varix, and hernia. It is remarked that recruits between eighteen and nineteen years of age give the greatest number of those passed fit for the service, the number gradually diminishing at each age from that upwards.

ABSTRACT OF REPORT OF LOCAL GOVERNMENT BOARD ON SMALL-POX IN DEWSBURY

THE last report of the medical officer of the Local Government Board, just issued, deals with an inquiry held towards the end of 1904 into the prevalence of small-pox in Dewsbury and district, in the West Riding of Yorkshire.

"For a long time," says Dr. S. W. Wheaton in his report, "Dewsbury town has been the centre of a movement in opposition to vaccination, and the surrounding urban districts have participated to a greater or less extent in this opposition. The Guardians of the Dewsbury Union have not only persistently neglected carrying out their duties under the Vaccination Acts, but have even taken up an attitude of opposition to the laws to which they were intended to give effect, with the result of very greatly discouraging the practice of vaccination."

"Although an interval of several weeks had occurred at the beginning of the year during which the hospital contained no patients, the Town Council had taken no steps to cleanse it or to put it in repair so that it would be ready in case of a fresh outbreak of small-pox. It was surrounded on three sides by an open rail fence, but there was no fence on that side facing the occupied portion of the cemetery; hence a particular patient found no difficulty in escaping at night time from the hospital, with the result that he was discovered at his home having supper with his relatives. The hospital consisted of a collection of small galvanised iron buildings, and had a very dilapidated and forbidding appearance; nearly all the windows were broken, the apertures having been stuffed with paper or rags. The interiors of the wards were very dirty."

On a second visit Dr. Wheaton found that "the Guardians had taken no action for the opening of a vaccination station, or for granting any facilities to the population for the obtaining of gratuitous vaccination or re-vaccination; or for informing people of the advantage of securing the protection afforded by vaccination and re-vaccination; or for publishing the means whereby they could obtain this protection for themselves and their children."

Of the adjoining Ravensthorpe Urban District, Dr. Wheaton writes:—

"The Ravensthorpe small-pox was attributed to Dewsbury, with which the district is continuous, and more particularly to the influence of the Dewsbury small-pox hospital, which was situate close to the boundary of Ravensthorpe. The district is one in which there had been for a long time strong opposition to vaccination, and although large numbers of persons were now seeking the protection of vaccination and re-vaccination, these were not necessarily persons who had been most directly exposed to infection. In many instances parents refused to have their children vaccinated, although small-pox was actually present in their dwelling, and thus many secondary cases occurred. It was almost hopeless to anticipate obtaining a site suitable for a small-pox hospital in such a thickly populated district. The administration of the Council for the prevention of small-pox was found very inefficient; they had no disinfecting apparatus, consequently the clothing of contacts and the clothing and bedding of sufferers by small-pox could not be properly disinfected, and owing to the retention of small-pox cases in their homes infected dwellings could not be disinfected; in most instances members of the invaded family who were going to work sought lodgings elsewhere, other members who were children or who had no occupation remaining at home. The Council were providing the persons retained at their homes with food and firing, and were employing men to bring food to them and to keep watch on them, in order to prevent them leaving their homes and mixing with healthy people at shops and other places of public resort; also these watchers were to stay with patients who were delirious or otherwise troublesome."

Of a second visit a month later, Dr. Wheaton reported:—"In spite of my advice on a former occasion the Council had not insisted upon the vaccination and re-vaccination of persons employed by them in connection with small-pox, and as a result three of them had already contracted the disease. I visited a number of the infected houses and found that nurses had not been provided, and in many instances persons who were only just recovering from small-pox and were quite unfit to be out of their beds were attending on relatives who were in the acute stage of the disease.

"In many instances healthy people had to sleep with persons suffering from small-pox, and children were being recklessly exposed to the infection, their parents in many instances refusing to allow them to receive the protection afforded by vaccination. In one small bedroom in a particular dwelling I found three adults suffering from small-pox; one single woman, aged 25, in one bed, and two single men in another; another healthy woman slept at night in the same bed with the female above referred to as suffering from small-pox. Parents still refused to have their children vaccinated. The Ravensthorpe people appeared, indeed, to be quite apathetic as regards small-pox and to have become accustomed to its presence, regarding it as a calamity which it was hopeless to fight against."

LITERARY NOTES.

A NEW edition of Dr. Cheadle's work on "Artificial Feeding and Food Disorders of Infants" has just been issued by Messrs. Smith, Elder and Company, revised and edited by Dr. J. F. Poynton, of University College, London.

***

MESSRS. BAILLIERE, TINDALL AND COMPANY have published this week new editions of Professor Moynihan's "Retro-peritoneal Hernia;" of Professor J. A. Lindsay's "Lectures on Diseases of the Lungs;" and of Dr. J. A. Shaw-Mackenzie's "Nature and Treatment of Cancer."

***

A NEW edition of "The Extra Pharmacopœia" has just made its appearance under the editorship of Drs. Harrison Martindale and W. Wynn-Westcott. This edition contains references to the pharmacopœias of Austria, Holland and Belgium of 1906 and to those of the United States and Spain of 1905. Mr. H. K. Lewis is the publisher.

***

DR. RENTOUL, of Liverpool, has a work in the press on "Race Culture, or Race Suicide?" The author's views are well-known to our readers, and the new work is "a plea for the unborn," and the giving of more attention to the begetting of a healthy race. It is written for medical and non-medical thinkers; and the causes of degeneracy are discussed in twenty-one chapters, while suggestions are made for the prevention of an increase of degeneracy.

***

MESSRS. JOHN WRIGHT AND COMPANY, Bristol, will shortly issue a complete set of large midwifery diagrams, designed for the use of lecturers to midwives and elementary students, by Dr. Victor Bonney. The set will comprise 160 figures upon 24 large sheets, 2 ft. 2 ins. by 3 ft. 4 ins. The figures are intended to constitute a complete pictorial course in the subject.

REVIEWS OF BOOKS.

MANUAL OF ANATOMY (*a*).

THIS treatise of anatomy will be completed in two volumes, the first of which is now before us.

Vol. I. contains Osteology, and the descriptive anatomy of the upper and lower extremities. The first 259 pages are devoted to Osteology. Pages 1 to 10 explain descriptive terms and discuss the structure, microscopic appearance, ossification, &c., of the bones in general. A clear and minute description of the individual bones and groups of bones follows. The drawings of the bones have the origins and insertions of muscles delineated in different colours, and all the prominent features are plainly labelled, thus further assisting the reader who is working up the already lucid text. An account of the structure, varieties, and ossification of each bone, with further figures, completes its description.

Pages 260 to 263 contain general considerations under the heading Arthrology. The special joints are not described here, but are dealt with in separate sections in the order in which they are met with in the course of an ordinary dissection. The description of each joint is complete in itself. The muscular relations, artery and nerve supply, movements and muscles concerned in them, are given in different paragraphs.

Pages 264 to 398 are allotted to the anatomy of the upper limb. The part for descriptive and dissecting purposes is divided into regions—as the back, pectoral region, &c. In each section is described the structures as they are encountered during dissection, commencing with the surface landmarks. The account of each structure is as comprehensive as possible, although it may not be confined to the region under discussion. In dealing with a muscle, for instance, a paragraph is given to its origin, insertion, nerve supply, and action. Full instructions for dissection occupy the last twelve pages of the upper limb. This guide is printed in small type, is of compact form, and besides giving the skin incisions and the method and order of procedure, enumerates in detail each structure which should be exposed. In the remainder of Vol. I. the lower limb is similarly treated.

The object the author, Professor Buchanan, has set before himself in writing this manual, and which he has achieved so successfully, is to combine a text-book of systematic and practical anatomy; and also to provide the student with a complete treatise on the subject, in which their examinational requirements have been constantly kept in view. The book is of convenient size, and the illustrations, which have for the most part been specially prepared for it, are very practical. The printing is excellent and judiciously interspersed with thick type. In conclusion, the whole arrangement of the work is admirably calculated to ensure its popularity as a text-book of anatomy.

(*a*) "Manual of Anatomy, Systematic and Practical, including Embryology." By A. M. Buchanan, M.A., M.D., C.M., F.F.P.S.Glas., Professor of Anatomy in Anderson's College, Glasgow; Examiner in Anatomy for the Triple Qualification of the Scottish Licensing Bodies; &c., &c. Vol. I. Osteology, Upper Limb, Lower Limb. Pp. xvi. and 596. Illustrations 266, mostly coloured. Demy 8vo, 12s. 6d. net. London: Bailliere, Tindall and Cox. 1906.

MONRO'S MANUAL OF MEDICINE. (*a*)

AMONG recent students' Manuals of Medicine, Professor Munro's work has quickly made for itself a popular place, as is sufficiently evidenced by the call for a second edition so soon after its first appearance. The volume is a compact, concise, business-like and yet scientific presentation of the principles and practice of medicine, freed from redundances and devoid of superfluities, yet supplying the students in crisp and readily grasped teaching, essentials to face the terrors of the examination room with confidence, and to meet the trials and responsibilities of practice in after years. In the present edition the whole work has been carefully revised and brought into line with the most recent views, much new additional matter appearing, particularly in such subjects as tropical splenomegaly, trypanosomiasis, and peroplasmosis. The sections are evidently intended to meet the requirements of the average student and for such the manual is likely to become a great favourite. The lengthy section on the nervous system is particularly good, one of the most scholarly which has come under our notice, and of itself sufficient to attract attention. A more liberal use of illustrations would certainly be an advantage, and in some parts would diminish the need for verbal descriptions, but as illustrations are not usually found in text-books on "medicine," the forty-one here given may be the beginning of favours to come. The volume is a valuable addition to the now popular "University Series" of Manuals for Students.

DU LABORATOIRE A L'USINE. (*b*)

THIS is a very good example of the "popular science" handbook, written as it is in literary French as untechnical as circumstances permit. Although the subject has no strictly medical bearing, it is interesting in that it traces the evolution of various departments of scientific research more or less closely allied to medical diagnosis and treatment, as, for instance, electro-chemistry, the Rontgen and Becquerel rays, and so on. One cannot but envy the lucidity of style in virtue of which the most recondite hypotheses and the most complicated reactions are brought within the reach of the general reader. After the perusal of such a volume even the non-scientific reader possesses a

(*a*) "Manual of Medicine." By Thomas Kirkpatrick Munro, M.A., M.D., Physician to the Glasgow Royal Infirmary, and Professor of Medicine in St. Mungo's College. Pp. XX. 1,023, with 41 plain and coloured illustrations. Demy 8vo. Second Edition. London: Bailliere, Tindall and Cox. 1906. Price 15s. net.

(*b*) "Du Laboratoire a l'Usine. By L. Houllevigue. (Paris: Armand Colin). Price 3fr. 50c.

good general idea of the immense progress that has been effected in the domain of industrial science during the last quarter—or shall we say half-century. He is enabled to follow step by step the laborious series of experiments which enabled Aver to perfect his wonderful incandescent gas light and the hardly less brilliant advances in the matter of electric lighting. That there remains ample margin for further discovery is evident when we are told that the ordinary candle only yields 14. the incandescent gas lamp 50, and the arc electric light 250, hundred thousandths of their theoretical value as illuminants. After the marvels of the heat rays come the marvels of cold, with which Professor Dewar's epoch-making demonstrations have familiarised the newspaper readers, though but few among them, we apprehend, could give even a vague idea of the mechanism by which these extraordinarily low temperatures are brought about. Unquestionably, however, the acme of interest is reached when we come to consider the properties of the various "rays," the disconcerting wasteless energy of radium, and are introduced to the "ions" in restless movement that constitute the various forms of matter. One's faith in the atomic theory is rudely shaken, and reason totters on its balance as we are confronted with the possibility of all matters being merely different conjugations of ethereal ions. The work comprises chapters on the evolution of machinery and the transformation of energy, the development of electrical energy by water power as well as on the subjects just referred to.

CLINICAL PATHOLOGY. (a)

THIS bulky, well printed and attractive volume is a translation of the third German edition of Professor Korchl's "Pathologische Physiologie." The translator has, however, employed the title given to the first German edition, which, although more familiar to English and American readers, does not perhaps quite so well emphasise the point of view and character of the work of the author as is clearly indicated in Professor Osler's introduction:—"Just as physiology deals with functions of the normal body, so pathological physiology deals with the functions when organs are placed under pathological conditions; and this is the subject of our discourse." In most medical schools general pathology and special morbid anatomy receive much attention, but morbid physiology is undoubtedly much neglected. This work, therefore, in its English dress, should be welcomed both by teachers and senior students. It is a work which should do much to minimise and discourage that unfortunate and altogether unscientific antagonism which, among many, undoubtedly exists between theoretical medicine as expounded in accordance with modern biological principles and the elaborate practice of the art and technique of present day clinical medicine. The avowed purpose of this book is to contribute to our knowledge of, and to awaken interest in, the theory of disease processes.

In these pages will be found admirable discussions regarding cardio-vascular derangement, the pathology of the blood, infection and immunity, morbid conditions impairing respiration, disorders of digestion, disturbances in nutrition and metabolism, including diabetes and gout. A chapter is devoted to the pathology of fever, and another to alterations in the urinary secretion. The concluding section is a fairly satisfactory presentation of nervous disorders. The value of the book is considerably increased by references which are given, but the almost entire absence of illustrations and diagrams (for there are only five figures given) we consider regrettable. The translator has done his work well. Perhaps wisely, a literal translation has not been attempted. Certain sections have been abbreviated and some of the material rearranged, but throughout the spirit of the original work has been loyally maintained. Some few additions on such subjects as blood pressure, surgical shock and hæmorrhagic pancreatitis have been made, and occasionally exception or amplification of the author's views have been made by the translator, but in such cases these are indicated. The original edition is fruitful in references to German literature. Many of these have been curtailed, and some English references have been added, but we venture to think that the work of clinicians and experimentors in this country have not received adequate attention. But this, of course, is no new feature in works of Teutonic origin. All concerned in the production of this work in its English, or should we not rather say American, dress, are to be congratulated, and we commend it to the serious study of all scientific physicians and those preparing for the higher examinations.

(a) "The Principles of Clinical Pathology."—A Textbook for Students and Physicians, by Dr. Ludolf Korchl, ordinary professor and director of the Medical Clinic in Strasburg. Authorised translation from the third German edition, by Albion Walter Hewlett, M.D. Instructor in Clinical Medicine at the Cooper Medical College, San Francisco; pp. 504. Philadelphia. J. B. Lippincott Co., 1905. Price 21s. net.

YELLOW FEVER. (a)

DR. HOWARD KELLY has found time in the midst of his strenuous life to carry through a task which should earn him the gratitude of all Anglo-Saxon medical men, namely, the writing of a biography of Walter Reed, army surgeon, bacteriologist, and discoverer of the intermediate host of yellow fever. To British medical men in particular this book will be acceptable, because so hasty is the advance of knowledge and so fleeting are men's recollections of the individuals who have established its landmarks, that the true romances of scientific achievement all too easily escape the attention they deserve. And this history of the work of the Yellow Fever Commission in Cuba is a romance in real life, none the less poignant because it was played out at a distance from the haunts of men and entailed a painful list of casualties among the bright and noble spirits which animated it. There is no devotion so complete, so utter, as that which knowingly and in cold blood offers life and health for the benefit of mankind, and of such could there be a finer example than was presented by the two young private soldiers who, with full knowledge of the almost certain consequences, offered themselves as subjects for the bite of infected mosquitoes? Major Reed did them no less than justice when he touched his cap and said, "Gentlemen, I salute you." Nor should we forget the calm self-sacrifice of Dr. Carroll and Dr. Lazear; the former was the first subject of an experimental mosquito bite, and the latter lost his life in the cause. It is good that all men, and especially all medical men, should learn and cherish in their memories their noble deeds. Dr. Kelly quite clearly establishes Walter Reed's claim to be the first to demonstrate the actual part played by the mosquito in the dissemination of yellow fever, first by his patient destructive criticism of the work of Sanarelli and others, and, secondly, by his constructive experiments. The Britisher may feel a little glow of patriotic pride when he reflects that without Mauser and Ross there would have been no Reed, but he will never be tempted to withhold his tribute of homage from the discoverer of a verity so pregnant with human happiness as that which Reed established. By no means the least valuable part of the book is that which deals with the previous history of yellow fever and the evolution of the idea of insect-transference, and in it full justice is done to the work of all Reed's predecessors. When, too, alongside it we read of the many definite facts demonstrated by the Yellow Fever Commission, and the immediately satisfactory results that ensued from prophylactic work founded upon the conclusions, we feel that this is a book of substantial and enduring worth. For it we have heartily to thank Dr. Howard Kelly, to whom we doubt not its preparation was a labour of pleasure and a labour of love; but he will none the less be gratified to know that his tribute to the memory of his dead friend will find an echo in the hearts of humble workers in the same field on this side of the Atlantic.

(a) "Walter Reed and Yellow Fever." By Howard A. Kelly, Professor of Gynecological Surgery, Johns Hopkins University. New York: McClure, Phillips and Co. 1906.

TUBERCULOSIS OF THE LUNG (*a*).

THIS unpretentious volume is a translation of the first two sections of Dr. Turban's "Beiträge zur Kenntnis der Lungen-Tuberculose," which was issued in 1899. Dr. Morland has done well in preparing the most important portion of this valuable work in a form acceptable to English readers. The translation has been undertaken with the author's co-operation, and additions and corrections have been made so as to adequately express the writer's latest views. The book consists of two papers, originally distinct. The first is "On Early Tuberculosis of the Lung and the Classification of the Disease into Stadia"; the second deals with "Physical Examination in Tuberculosis of the Lung." The title of the translation is therefore seen to be something of a compromise as well as a convenience. There is much in these pages which will be of great interest to the expert in consumption. The section which deals with classification of cases is highly suggestive, but the division adopted is not one likely to commend itself to English readers. Dr. Turban would have us tabulate cases in three groups:—(1) Disease of slight severity, affecting at most one lobe or two half lobes; (2) Disease of slight severity, more extensive than (1), but affecting at least two lobes; or severe, and affecting at most one lobe; (3) All cases of greater extent and severity than (2). It is certainly true that a uniform grouping of cases is most desirable if we are to attain to any satisfactory comparison of results as recorded in the reports of the many institutions devoted to the treatment of the consumptive, but Dr. Turban's suggestion is hardly likely to be adopted. His so-called "Schema" for comparative statistics offers but little that is new or likely to be helpful. The portion of the work of greatest interest and value is that which deals with the physical examination of the chest of the tuberculous, and here, very justly, insistence is made on the importance of certain signs which are only too often overlooked or neglected. More than six pages of bibliography appear, but we are sorry to see that English writers are most inadequately, and, as we think, unfairly represented. We could have wished that the translator had included the results of Dr. Turban's lengthy experience of sanatorium treatment at Davos, which, at the present time, when the value of institutional treatment is being much discussed in this country, would have been of scientific interest and practical service.

NEW WORKS ON CONSUMPTION.

THE first of these volumes is, as its title (*a*) suggests, a comprehensive exposition of the inter-relations of civilization and consumption, and a detailed discussion of the influence of this fell malady on man's life and human affairs generally. It is no mere academic treatise or medical handbook, but a medico-sociological study which should appeal to the thoughtful layman as much as to the medical practitioner and health officer. The author has undertaken no light task in attempting to enlist the attention of both physician and layman, but even a cursory glance at these attractive pages will afford evidence that no small measure of success has resulted. The scope of the work is extensive; economic, legislative, sociological, humanitarian, as well as purely hygienic: pathological, and clinical features of the problem are dealt with. In some instances the presentation has been incomplete and even superficial, but where so wide a field has had to be covered, a measure of insufficiency is unavoidable. The author writes with true American verve. His style is lucid and incisive and intensely human in its sympathy, and not lacking in the saving element of humour. The work is most informing and highly suggestive and the striking illustrations are in some cases almost sensational in their tragic and insanitary features. Dr. Huber wanders into many fascinating byeways, as, for instance, where he details the effects of consumption on literature and art, or where he discusses the psychic element in the disease. A particularly valuable section of the work will be found in the appendices, where, amid much of practical service, appear lists of American Societies and Committees for the prevention of tuberculosis. The work is one which should have an extensive circulation not only in the land of its birth, but among all English-speaking people. Its perusal should accomplish much in stimulating thought and energising action among those responsible for individual and collective effort in stemming the death-dealing tide of this devastating scourge.

Sir William Broadbent says, in his introduction to this unpretentious monograph (*b*) (second on our list): "The economic, the philanthropic, the preventive, and the educational [aspects of the subject] are discussed by Dr. Bardswell in an eminently practical spirit, and the whole book is the outcome of experience inspired by enthusiasm and guided by common sense." We may add that the major part of the volume is a detailed description of twenty-five cases carefully observed and thoroughly investigated by the author at the Sheffield Royal Infirmary and the Mundesley Cottage Sanatorium. In addition to the clinical data, there are interesting notes on the social and economic conditions of each patient. The most suggestive portion of the work is the all too short section devoted to conclusions, and based as they are on so small a number of cases, they can hardly be considered as conclusive. Dr. Noel Bardswell thinks that "of all admissions to a sanatorium for the working classes we may expect permanent restoration of health and normal working capacity in 41.7 per cent. Death in the course of from two to five years after discharge in 41·7 per cent. Some degree of permanent restoration of health and capacity for work in 16·6 per cent." Although lacking in originality and presenting no statesmanlike grasp of the problem, the monograph is interesting, and to those who have studied the subject "on the spot" will be suggestive and helpful, although many will differ from the author on important points. As a personal contribution to a problem of great magnitude, it is of considerable merit, but it does little to advance our knowledge and leaves us still in the experimental stage. The title is not particularly happy and is not free from the charge of being misleading. Half-a-guinea seems an unusually high price for a small work of 200 pages with three illustrations of the grounds of the Sheffield Infirmary and a picture of the Mundesley Cottage Sanatorium.

The third work (*c*) is a diminutive volume written in a simple and unpretentious style of instruction for the home guidance of the consumptive patient who is seriously directing his life towards recovery. It is a concise, clear, and dogmatic presentation of rules which are essential in the conduct of the hygienic treatment of pulmonary tuberculosis. Twenty-five rules are given, which on the whole are judicious and wisely expressed. The importance of temperature as a guide is rightly insisted on, and suitable charts for the use of the patient are given. The little manual is well intentioned, and medical practitioners may wisely provide their consumptive patients with a copy, for they may be assured that the information is not only reliable, but is set forth in simple language which can be readily understood.

(*a*) "The Diagnosis of Tuberculosis of the Lung," with Special Reference to the Early Stages. By Dr. K. Turban. Translated by Egbert C. Morland, M.B., B.Sc. Lond., with an Introduction by Sir Dyce Duckworth, M.D., LL.D., F.R.C.P. Pp. viii., 135. (London: John Bale, Sons and Danielsson, Ltd., 1905. Price 5s.)

MEDICAL NEWS IN BRIEF.

A Split in the Anti-Vivisection Camp.—The Vivisection Inquiry.

We reproduce the following interesting letter published by the Editor of *The Tribune*.

"SIR,—In a recent issue you give some prominence to the views of the Hon. Stephen Coleridge on the above subject. Had these views been given merely as representing the attitude of Mr. Coleridge himself, or of the National Anti-Vivisection Society, of which he is both hon. secretary and treasurer, they might be allowed to pass. But when Mr. Coleridge's views are put forward as those of "the Anti-Vivisection Society," and when reference is made to him as "the leader of the Anti-Vivisectionists," it is surely necessary that someone should, on behalf of the many thousands who disagree with his policy, publicly decline to allow Mr. Coleridge to speak for them, and to claim a position to which he is not entitled.

"The 'points' given by Mr. Coleridge to the Royal Commissioners proclaim quite unmistakably that—at present—he is not an anti-vivisector at all, but merely one who wishes to see vivisection carried on under slightly different conditions. For these points amount to the suggested prohibition of the following:—

"(1) The use of the drug curare.

"(2) Experiments involving protracted agony.

"(3) Experiments performed for the mere acquisition of knowledge.

"(4) Demonstrations before students.

And they include the sanction of the following:—

"(1) All painful experiments in which the agony is not 'protracted,' provided they are performed for the purpose of serving the human race.

"(2) The system of medical inspection at present in vogue, whereby one vivisectionist is set to watch another.

"Now it is obvious that the distinction between experiments for the advancement of knowledge and experiments for the service of humanity cannot be drawn, inasmuch as a vivisector can always argue that knowledge not immediately and demonstrably useful may prove useful under certain contingencies in the future. It is also obvious that if an advanced scientist is to be allowed to vivisect, he must receive the necessary training when a student. Two of Mr. Coleridge's points are thus proved impracticable. I should not, however, have ventured on this criticism were it not for the unfortunate circumstance that opponents of the entire system of vivisection have been misrepresented by the supposition that they follow a 'leader' who has made a public statement suggesting to the Commissioners that they should not oppose painful experiments on animals except when the agony is protracted and the object useless.—Yours, etc.

"B. E. KIDD,
"Secretary, British Union for Abolition of Vivisection."

'32, Charing-cross.'

Diphtheria Epidemic at Melbourne.

AN important conference between the Parochial Committee and the medical officer of health, the local doctors, and others, was held last week at the Council School, Melbourne, Notts., concerning the prevailing epidemic of diphtheria and the general sanitary condition of the town. There were present—Lord Walter Kerr, Mr. W. Garratt, Mr. Bagwell, Dr. Hogg (medical officer of health), Drs. Moore and Tredinnick, Mr. Mallalieu, J.P. (chairman of the Shardlow Rural District Council). Mr. Adcock, who presided, explained that the conference was called to devise, if possible, an effectual way of stamping out the epidemic.

Dr. Hogg said that Melbourne had suffered for some time from scarlet fever, which was now abating, but they were threatened with an outbreak of diphtheria. There had been nine cases in the past fortnight. It was fortunate they were of a mild type, but this made it the more difficult to stamp out, because some children might have it so slightly that it would not be discovered until it had developed. They went to school within a day or two of having a sore throat, and thus spread the infection. As far as house sanitation was concerned, Melbourne compared favourably with any other place in the district. It was now generally recognised that diphtheria was spread by direct contact, although defective drainage had a predisposing influence in spreading it.

Considerable discussion followed, the general feeling being that the gullies were not flushed sufficiently often, and it was eventually decided to recommend the Parochial Committee to draw up a petition, to be signed by the ratepayers, asking the District Council to allow the Parochial Committee to undertake the flushing of the sewers, and refund the cost thus incurred.

[The above congress is of importance, as it is held at the outset of an outbreak, and not deferred, as so often happens, until the epidemic has attained formidable dimensions.—ED. M.P. & C.]

The Extirpation of Malaria.—Liverpool and the Campaign in Greece.

ON the 17th inst., under the auspices of the Liverpool School of Tropical Diseases, a gathering of gentlemen concerned in the anti-malaria campaign in Greece took place at the University Club, Liverpool. The guests were invited to lunch by Sir Alfred Jones, chairman of the School, to meet Professor Dr. Savas, of the University of Athens, and physician to the King of Greece. The chair was occupied by the Lord Mayor of Liverpool (Alderman Joseph Ball).

Alcohol as Medicine.—Local Government Board View.

AT the meeting of the Epping Board of Guardians last week, Dr. Fuller, medical officer to the Local Government Board, on behalf of that body, severely criticised the expenditure of one of the district medical officers of £16 15s. 4d. for the half-year on wines and spirits. He said that the Local Government Board had always agreed that the use of alcohol was not necessary in the treatment of diseases, and they wished to impress on boards of guardians those views. In the case in question, the situation entirely arose through the pronounced views of a certain medical man in favour of the use of spirits. It was decided to write to the Local Government Board in order, as the chairman remarked, to get these views in "black and white."

Arbroath Water Works.—The Typhoid Outbreak.

AT a recent meeting the Brechin District Committee had before them a joint report from Dr. Dewar, Medical Officer, and Mr. J. Anderson, Sanitary Inspector, on the outbreak of typhoid fever among the workmen engaged at the construction of the Arbroath Corporation reservoir at Glenogil. The report stated that, in consequence of several cases of undoubted typhoid fever having occurred among the workmen, and a number of cases having occurred in the lower valley of the Noran, a district which for many years had been exempt, and these cases being exclusively confined to those who drank the Noran water, or were indirectly infected from those who had done so, there was strong suspicion that the disease

had been introduced by the labourers at Glenogil Water Works, and disseminated by the pollution of the Noran stream. Their inquiries showed that generally speaking, the huts were clean and fairly well ventilated; the beds also, as examined, were as clean as could be expected. The disposal of the slop water was not satisfactory. Originally intended to be filtered through gravel, it was now reaching the Keillor Burn in an impure condition at several places. Refuse of all sorts was strewn over the ground in the neighbourhood of the huts. Owing to the configuration of the district it was impossible to suggest an alternative or preferable site for the huts. No fresh case had occurred for three weeks, and they recommended certain improvements on the present sanitary arrangements.

Tropical Medicine Research.

HIS MAJESTY the King of the Belgians has recently demonstrated his interest and approbation in the work of the Liverpool School of Tropical Medicine by decorating Professor Ronald Ross, C.B., F.R.S., Professor R. Boyce, F.R.S., etc., and Dr. J. L. Todd. The honour thus conferred upon them is not to be allowed to pass unnoticed locally, for the recipients are to be entertained at lunch by the Lord Mayor, at the Town-hall, on Monday next, and invitations have just been issued to a numerous company to meet them.

Death under Chloroform.

DURING a dental operation at a well-known Liverpool dentist's last week, a lady patient unfortunately succumbed under the anæsthetic. At the inquest subsequently held, it was proved that the drug was carefully and skilfully administered, and that no blame was attachable to the administrator or the operator, and a verdict in accordance with the evidence was returned.

Alleged Fraudulent Westminster Collector.

HUGH BEATON GORDON, 35, who gave an address at Atherfold Street, Clapham, and described himself as a debt collector, was charged last week on a warrant before Mr. Horace Smith at Westminster Police Court, with fraudulently converting a sum of over £10, entrusted to him, to his own use and benefit. The prosecutor, a medical man, of Upper Kennington Lane, about twelve months ago responded to a circular sent by prisoner to medical men offering to collect outstanding accounts. There was to be a quarterly settlement, but it was alleged that sums which prisoner obtained never found their way to the prosecutor, and that his letters, though not returned, remained unanswered. Detective-sergeant Long said that he had had great difficulty in tracing the prisoner, and that it was only by a ruse that he was brought back to London. No doubt there would be other charges against him. Prisoner was remanded and bail refused.

A Sidelight on Medical Education.

THE examinations for admission to the Army, Navy, and Indian Medical Services are especially interesting in view of the fact that they are the only competitive medical examinations which exist. Since the spring of 1902, altogether 693 men have contested for 434 commissions. Competition has been keenest for the Indian Medical Service and least keen for the Navy. English Candidates have greatly preponderated, and England has had the least proportion of failures.—*Tribune.*

Royal College of Surgeons of Ireland—Post-Graduate Course.

The second post-graduate course of the year commenced on Monday last, the 24th inst., and continues daily until October 3. The various hospitals at which classes will be held include Stevens', the City of Dublin, Sir Patrick Dun's, the Adelaide, the Meath, the Richmond, the Rotunda, the National Maternity, the Coombe, the Mater, and the Victoria Eye Hospitals, and other special hospitals and institutions. All information regarding the hour of classes, etc., can be obtained from Professor Fraser at the College.

Royal Misericordiae Hospital, Dublin.

A dinner of the past and present students of this hospital will be held at the Shelbourne Hotel, at 7.30 p.m., on Saturday, October 6th, when Sir Christopher Nixon, Bart., will be entertained by the Medical Board. Dinner tickets, with wine, 21s.; without wine, 10s. 6d. each person. Past students may invite not more than one guest each. Cards of invitation will be sent to guests by the secretary. Past or present students who desire to be present should send their names, with the names and addresses of their guests, and the necessary subscriptions, to Dr. Martin Dempsey, 35, Merrion Square, Dublin. No subscription will be received and no withdrawal accepted after 9 a.m. on Thursday, October 4.

Royal Academy of Medicine in Ireland.

The Annual General Meeting of the Royal Academy of Medicine in Ireland will be held in the Royal College of Physicians on Friday, October 12th, at 4.30 p.m., when the Annual Report will be submitted, and the officers and members of Sectional Councils will be elected. Nominations of candidates for office, whose sanction has been obtained, must be sent to the General Secretary in writing not later than Tuesday, October 2nd. The offices for which candidates may be nominated are: President, General Secretary and Treasurer, Secretary for Foreign Correspondence, President of the Section of Anatomy and Physiology, Member of Council in the Sections of Medicine, Surgery, Obstetrics, Pathology, Anatomy and Physiology, and State Medicine.

University of Durham.

THE following candidates have passed the Second Examination for the Degree of Bachelor in Medicine:—John Pritt Jackson, in anatomy, physiology, and materia medica, with second-class honours. Pass List: Alexander Hay Bower, Leonard Foster Browne, John George Campbell, B.A., Harold Alexander Cooper, Reginald Cyril Herbert Francis, Patrick Albert Galpin, Raghunath Vithal Khedkar, L.R.C.P.&S., L.F.P.S., G. Ernest Percy Martin, Theresa de Gournay Miller, Ruth Nicholson, Robert Raffle, Charles Elias Reindorf, Harold Widdrington Sykes, George Huntly Wood.

SIR WILLIAM TRELOAR has called attention to his Crippled Children's Fund, the aim of which is to provide a Christmas banquet for London cripples at the Mansion House. To those who cannot attend hampers are sent. This most excellent charity is supported yearly by King Edward. It is specially interesting to medical men to note the following:—

The Fund which is raised usually provides a balance to be expended in surgical instruments, artificial limbs, invalid chairs, and other benefits greatly appreciated by the suffering little ones.

PROFESSOR BOEHNER, of the McGill University, reports that an epidemic of measles has broken out among the Indians in Northern Quebec. Forty are dead. He adds that food is scarce.

WE regret to report the accidental death of Major Cecil Birt, of the Royal Army Medical Corps. Deceased, who was stationed at Chatham, met with a bicycle accident near Reading, and sustained injuries that proved rapidly fatal.

GEORGE MORGAN, a medical student, was on Monday last committed for trial at the Central Criminal Court for obtaining money under false pretences from Dr. Eason, of Guy's Hospital, Mr. Dickey, house surgeon of the Miller Hospital, Greenwich, and others.

DR. HENRY GERVIS, of Brighton, has been unanimously elected Mayor of that important borough for the ensuing year.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

On the Technique of Operations on the Central Nervous System.—Sir Victor Horsley (*Brit. Med. Journ.*, August 25th, 1906) points out that the prominent characteristic of intracranial disease is its liability to produce optic neuritis. It may concomitantly cause severe headache and vomiting. The most important factor in the production of optic neuritis is the intracranial tension. As soon as optic neuritis (not of toxic or anæmic origin) is diagnosed, palliative surgical treatment at least should be undertaken as soon as possible, so as to prevent complete atrophy and total blindness. In rare instances, the neuritis may begin to subside after even the first stage of opening the skull: but it is, as a rule, necessary to make a free opening into the dura mater to effect this purpose. One reservation must be made, that is, in cases where the tumour involves the optic tract. Optic neuritis usually commences on the side of the lesion. In the consideration of the details of all operative procedure the posture of the head is a most important one. The head should be elevated on a suitable head rest to diminish the pressure on the venous sinuses, and the shoulders slightly raised, so that the glottic respiration is not interfered with. The author always employs chloroform as an anæsthetic, using Vernon Harcourt's regulator for its administration. As a rule, 2 per cent of chloroform in the air respired is given for about five minutes before the incision of the skin and reflexion of the flap, which constitutes the maximum pain period of the operation. The bone may be removed at 1 per cent. As the dura is a sensitive membrane, the dose should be somewhat raised just previous to its incision. As soon as the dura is opened the encephalon can be dealt with without causing any pain, and the operation is done under less than ·5 per cent. of chloroform. After the encephalic region is dealt with the percentage always should be raised to ·7 or 1 per cent. to provide for the skin sutures. It is necessary during all operative procedures on the skull and its cavities to prevent cooling by radiation from the brain exposed in the wound, as well as from the body surface generally. The wound should therefore be constantly irrigated with a solution of 1 in 10,000 of sublimate or with saline, at a temperature of 115°. This hot lotion also serves the purpose of arresting capillary and arterial hæmorrhage. As regards hæmorrhage, the first general principle is the recognition of the fact that as few vessels as possible should be obstructed, to prevent softening of the brain areas supplied by them. Where it is necessary to remove large portions of the brain, the branches of vessels to be divided should be severed as far as possible from the trunk. Tying the carotid artery with the view of producing a large control of the blood flow from the cerebral arteries is a measure to be avoided. Serious and even fatal secondary œdema and softening have often followed this procedure. Tying all the arteries around the lesion before extirpating it is the best plan. The incision in the brain should be commenced below and carried upwards and towards the mesial plane. Hot irrigation is the safest and easiest method of arresting capillary oozing. The author is also in the habit of controlling capillary and venous oozing by requesting the anæsthetist to direct a stream of oxygen gas through the air inlet of the Harcourt regulator, and so quickly abolish any asphyxia. Bleeding from veins in bone can be with certainty arrested by plugging with wax. Wounds in sinuses must be closed with a fine lateral suture on a round needle. Sir Victor Horsley considers that shock can be in a great part avoided by dividing the operation into two stages, the interval between them being about five days. The first stage consists of the opening of the skull, the second of the opening of the dura mater and removal of the lesion. The best method of opening the skull is by first removing a trephine disc, then marking with a large saw the area to be removed and finally cutting away the bone with a large bone forceps. In reference to sepsis the author asserts that the less drainage is employed the better, and that every effort should be made to close the skin wound as early as possible. In discussing general consideration, the method of reaching tumours of the base is described. This is best done by displacement of the brain, by inserting a flat spatula beneath the brain between the more important emissary veins which anchor the cerebral hemisphere to the dura mater at various points. Sir Victor Horsley makes the following general deductions on the question of the surgical treatment of malignant disease of the encephalon: (1) That operation should be resorted to as early as possible; (2) the tumour should be, if possible, freely exposed and examined, and extirpated with surrounding tissue; (3) that if it cannot be removed with ut undue interference with important or essential structures there remains some possibility of the tumour undergoing retrogression in a certain number of cases. S.

A Series of Cases in which Collections of Stones formed in the Prostatic Urethra. — Morton (*Brit. Med. Journ.*, August 11th, 1906) reports three such cases in all of which the presence of the stone was associated with a stricture of the urethra, and thus the passage of the stones out of the urethra was obstructed. The stricture was not very tight in any of the cases, and was easily dilated to a considerable extent. The prostatic uretha was greatly dilated in each case, so that prostatic tissue could not be recognised. The stones were mostly phosphatic, and there was no reason to believe that they were originally formed in the prostate. The author considers that the urine remaining in the dilated urethra after micturition deposited phosphates and so formed calculi. The prostatic urethra was so dilated in one of the cases that by pressure on it a stream of urine could be forced out of the perineal fistula which remained after operation. In none of the cases was the stricture just in front of the prostatic urethra. In one case it was scrotal, in another at the junction of the scrotum and penis, and in the third quite near the meatus. Yet, as one would expect, there was no general dilatation behind the stricture. Treatment is unsatisfactory. In Case I., stones were removed by incision six times. Once a stone which caused retention was removed by forceps. The patient frequently passed other stones. Perineal section to remove the stones, together with dilatation of any stricture or strictures is clearly indicated, also to keep the stricture well dilated, so that stones may have a chance to pass when small. In one case the author after considerable difficulty succeeded in forming a permanent perineal fistula in order that urine might not remain and deposit in the dilated part of the urethra, but even this has not stopped the formation of stones for the patient frequently passes small ones.

Antipyrin Amaurosis.—F. C. Hclz (*Archives of Ophthalmology*, Nos. 2 and 3, 1906) relates a case in which a man, æt. 33, who was a "martyr" to migraine, took twenty-six five-grain tablets of antipyrin in forty-eight hours. During this time his sight failed until at the end of the forty-eight hours it was almost extinguished. Under iron internally and pilocarpin subcutaneously, the patient recovered full vision. Three other cases of this form of amaurosis have been recorded. In one, a lady took fifteen grains and in five minutes was perfectly blind. The blindness lasted

one minute and she was quite well in three days. In a second case, a lady took fifteen grains of the drug after a meal, and in three minutes was down with violent headache, tinnitus, vertigo, palpitation, dyspnœa, and cold perspiration. In twenty minutes she lost her sight, and the blindness lasted thirty minutes. In the third case, a man had been taking three tablets of antipyrin (ten grain pro dose) at one hour intervals, when he had an attack of migraine, which was about every week. After several months his sight became blurred, but there is no mention as to how long it remained so. It would seem that antipyrin has no serious effect on the eye, if taken only occasionally, and in moderate doses. But if large doses are taken in a short time, blindness is liable to set in suddenly, and run to profound amaurosis which may last for many months. M.

A Case of Inoperable Cancer Treated with a Bacterial Vaccine of Neoformans. — Spicer and Wright (*Journ. of Laryn., Rhin., and Otology*, June, 1906) record a case of cancer in a Balaclava veteran, æt. 75, in which the tumour occupied the site of the left tonsil, fauceal pillars, side of the tongue, and extended down the wall of the pharynx. The faucial isthmus was so blocked that laryngoscopy with the smallest mirror could not be practised. The tongue could not be extruded. The surface of the growth was studded with bloated fungous granulations imbedded in copious fœtid fluid. There was a large mass of hard swollen glands behind angle of jaw, dysphagia, and much pain in left side of head and ear. Professor Wright treated the case by a vaccine of Micrococcus Neoformans. Favourable changes commenced at once and continued to increase for five or six weeks, after which matters came to a standstill. The favourable changes were: Shrinking of the faucial mass rendering laryngoscopy possible, lessening of ulcerated surface, which became like a healthy granulating surface, loss of fœtor, disappearance of dysphagia and pain, the tongue became less rigid, and the external glandular mass shrunk enormously. Although a cure is not claimed, the authors consider the improvement marvellous both locally and in the patient's general condition, and look upon the case as one of good augury for the influence of the treatment. Professor Wright's account of Doyen's Micrococcus Neoformans and of the *rationale* of the treatment is interesting. He states that Dr. Spicer's case is one of a batch of five where he inoculated the M. neoformans vaccine in which there was a striking result. Two have died; one has remained stationary, while another shows marked improvement. M.

The Treatment of Cancer of the Rectum.— Samuel Gant discusses under three headings (*New York Med. Journ.*, August 18) the treatment of rectal carcinoma. The treatment may be palliative, surgical palliative, or radical operative treatment. The most important feature in palliative treatment is the prevention of obstruction or its relief if it should already have occurred. This is accomplished by diet, the use of such remedies as olive oil, castor oil, salts, and such drugs as will soften or liquify the fæces, so that they may easily pass the constriction. Where fæcal impaction has occurred, purgatives are contra-indicated, copious enemata should be given through a colon tube, If this fails, the fæcal mass must be broken up with the finger or a scoop, and washed out. The bowel should be frequently washed out with some antiseptic solution, to prevent secondary ulceration of the mucous surface taking place. By means of the X-ray much can be accomplished in diminishing pain, retarding the growth of the neoplasm, and in prolonging life; but in the writer's hands it has had no curative effect whatever on cancers of the rectum. The surgical palliative measures for the relief of rectal or sigmoid carcinoma are, in the order of their importance, colostomy, proctotomy, curettage, and forcible divulsion. Curettage should only be resorted to if the growth is within three inches of the anus. Proctotomy and forcible divulsion can only be of use when the disease is situated at or just above the anus. In all cases where the growth is not fixed to adjacent structures, where there are no metastases in other organs, and where the patient is not extremely debilitated, the author believes that a radical operation should be done. The operation he performs is either superior or inferior proctectomy, the former in the case of high growths, the latter if the cancer is situated low down in the bowel. In inferior proctectomy the soft parts only are divided, while in the superior operation the coccyx and a portion of the sacrum are removed to allow of freer access to the bowel. The mortality for the inferior operation is about 7 per cent. and for the superior about 21 per cent., while about 16 per cent. of the cases are absolute cures. The writer concludes by stating that after a personal study of more than 200 cases of rectal cancer, treated by palliative surgical palliative procedures, and the radical operation, he unhesitatingly advises complete extirpation of the growth when possible, because this is the only procedure which tends to relieve suffering, and offers to the patient a chance of permanent recovery from his affliction. G.

Gastrostomy.—E. Tavel (*Zentralblatt fur Chirurgie*, June 9) calls attention to a new method of performing gastrostomy. The ordinary operation has two faults, in that the stomach is left in contact with the abdominal wall, which must be hurtful to the functions of the organ; in the second place the permanent opening into the stomach is too small to permit any but soft food-stuffs being introduced; for these reasons the author performs the following operation: A piece of the jejunum is isolated about five inches in length, divided between clamps, care being taken not to interfere with its blood supply; this loop is held to one side, while an end-to-end anastomosis is made between the cut ends of the jejunum. An opening is then made through the mesocolon, and the isolated portion of gut brought through this; the distal end of the loop is then implanted in the anterior wall of the stomach, and the proximal end attached to the abdominal wall. The operation has, in the author's opinion, only one disadvantage, that is, that it takes longer to perform than the ordinary methods of gastrostomy. G.

The Treatment of Cancer of the Stomach. — In a lecture on this subject, Mayo Robson (*Lancet*, August 18) deals first with the diagnosis, and then the treatment of gastric carcinoma. He believes that he has now collected sufficient evidence to prove the following: (1) How desirable it is to make an early diagnosis of cancer of the stomach, in order that a radical operation may be performed at the earliest possible moment. (2) That it may be needful to perform an exploratory operation to complete or confirm the diagnosis. (3) That such an operation may be done with little or no risk in the early stages of the disease. (4) That even where the disease is more advanced and a tumour perceptible, an exploratory operation is, as a rule, still advisable in order to carry out radical or palliative treatment. (5) That where the disease is too extensive for any radical operation to be done, the palliative operation of gastro-enterostomy, which can be done with very small risk, may considerably prolong life, and make the remainder of it much more comfortable and happy. (6) That some cases, thought at the time to be cancer, too extensive for removal, may after gastro-enterostomy clear up and get completely well. (7) That in cases of disease of the cardiac end of the stomach too extensive for removal, the operation of gastrostomy may considerably prolong life, and prove of great comfort to the patient by preventing death from starvation. (8) That even where the disease is too extensive for removal, or for a gastro-enterostomy being performed with a fair chance of success, the operation of ejunostomy may prove of service to the patient. (9) That where a radical operation can be performed the thorough removal of the disease may bring about as much relief to the patient as does the operation for the removal of cancer of the breast, uterus, and other organs of the body, and that in some cases a complete cure may follow. G.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

EUCAINE.—Naphtholum camphoratum is not without danger as a local anæsthetic. Several fatalities have been recorded. Probably it is only dangerous in oily solutions.

DEVONIAN.—1,085 cases were notified in Bristol last year. There were 39 deaths, giving a case mortality of 3·5 per cent.

ATBARA.—The commonest specie of locust in Khartoum is pœciliocerca hierogliphica. It lives chiefly on the Ushen plants.

THE METHYLENE BLUE REACTION IN ENTERIC FEVER.

ERRATA.—In Dr. Rolleston's paper which appeared in our last week's issue, the following corrections should be made:—In seventh line, page 303, "Very mild cases of co ivalescenee" should be "Very mild cases or convalescent." On page 304, line 33, for "I was employed," read "I employed it."

HATLESS WOMEN.

DEAR SIR,—*Re* "The Hatlessness of Womankind" (MEDICAL PRESS AND CIRCULAR, September 5th), it may possibly interest you to observe the different impressions created in men's minds by their various professional training, &c., *vide* Corinthians, Chapter XI., and contrast with your article under the above title.

Yours truly,
DUBLIN.

[The writer of the paragraph dealing with the hatlessness of women was aware of the text on the literal interpretation of which the objection of various clergymen to feminine hatlessness in church is founded.—ED. M.P. and C.].

LYMPH.—A paper on the subject of the ability of vaccine lymph to stand very low temperatures was published by the Local Government Board on July 31st of this year.

SENEX.—"The Garden of the Unforgotten" is described in Sir Frederick Treves' book, "The Other Side of the Lantern."

PRESCRIPTION.—The proper phrase would be: "Cochlearia duo ampla omni horâ capienda dome singultus cessavérit." But prescription latin does not pretend to be very elegant.

BACTERIA.—See paper by Metchnikoff, "Zur Immunitätslehri." Congr. f. Inn. Med., 1892, 282.

MR. G. G. MONCK.—The number of this journal containing the lecture is out of print, but a reprint in pamphlet form may now be had through your bookseller. Price, 1s.

S. J. R. has not sent his name and address; we are, therefore, unable to return his MS. His effusion is amusing and would doubtless be accepted by one of the lay weeklies, but it is not of sufficient professional interest for the columns of a medical journal.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 26th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. H. L. Barnard: Clinique. (Surgical.)

THURSDAY, SEPTEMBER 27th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

Vacancies.

Aberdeen Royal Asylum.—Senior Resident Assistant Physician. Salary £200 per annum. Applications to Dr. Reid, the Medical Superintendent.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to Edmund Forster, Secretary.

City of Liverpool.—Assistant Medical Officer of Health. Salary £250 per annum. Applications to Edward R. Pickmere, Town Clerk, Town Clerk's Office, Liverpool.

City of Liverpool.—Infectious Diseases Hospital.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, washing, and lodging at the Hospital. Applications to the Chairman of the Port Sanitary and Hospitals Committee, Town Clerk, Municipal Offices, Liverpool.

City of Birmingham Asylum, Rubery Hill, near Birmingham.—Male Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, &c. Applications to the Medical Superintendent.

Cheshire County Asylum, Macclesfield.—Junior Assistant Medical Officer. Salary £140 per annum, with apartments board (no alcohol), and washing. Applications to the Medical Superintendent.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Applications to W. M. Wilcox, Secretary.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Lewis Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer.—Salary £104 per annum, with furnished apartments, board, coal, gas, washing, and attendance. Applications to Wm. Edwd. Nicholson, Hon. Sec., 213 High Street, Lewes.

St. Pancras and Northern Dispensary, 126 Euston Road.—Resident Medical Officer. Salary £105 per annum, with residence and attendance. Applications to the Hon. Secretary, H. Peter Bodkin, 23, Gordon Street, London.

The Chorlton and Manchester Joint Asylum Committee.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to Henry Woodhouse, Clerk to the Joint Committee, Chorlton Union Offices, All Saints, Manchester.

Wolverhampton and Staffordshire General Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to J. Stephen Neil, House Governor and Secretary, Wolverhampton.

Appointments.

BALL, C. R. H., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Hunstanton District of the county of Norfolk.

GLENNY, ELLIOTT T., B.S.Lond., House Physician at the Essex and Colchester Hospital.

IVENS, FRANCES, M.B., M.S.Lond., Honorary Medical Officer for Diseases of Women at the Stanley Hospital, Liverpool.

LAWSON, THOMAS CORNELIUS, M.R.C.S., L.S.A., Medical Officer for the Hartland District by the Bideford (Devon) Board of Guardians.

MCILROY, A. LOUISE, M.D., L.M.Rotunda, Extra-Dispensary Gynæcologist at the Glasgow Royal Infirmary.

MOORE, C. A., M.B., B.S.Lond., House Surgeon at the Stanley Hospital, Liverpool.

MOORE, P. M., L.R.C.P. and S.Irel., Dispensary Officer for the District of Strangford, Downpatrick.

MORRISON, J. W. H., M.B., B.S.Durh., B.Hy., D.P.H., Certifying Factory Surgeon for Blaydon, Whickham, and Ryton Urban Districts, and Medical Officer of Health of the Blaydon Urban District.

PARRY, T. WILFRED, M.B., Ch.B.Liverp., House Physician at the Royal Southern Hospital, Liverpool.

THOMSON, CHARLES SAMSON, M.B., Ch.B.Glasg., House Surgeon at the Sunderland Infirmary.

Births.

FRASER.—On Sept. 16th, at Trevenna, Slough, the wife of Herbert Fraser, M.R.C.S., L.R.C.P., of a son.

LYLE.—On Sept. 18th, at 97 Gordon Road, Ealing, the wife of Frederick W. Lyle, M.D., of a daughter.

NASH.—On Sept. 20, at Oulton House, Accrington, Mary Monica, wife of Edwin H. T. Nash, M.R.C.S., L.R.C.P., of a son.

NEWTON.—On Sept. 21st, at Brook Hill, Sheffield, the wife of Duncan Gray Newton, F.R.C.S., of a son.

STARES.—On Sept. 12th, at The Limes, Swanley Junction, Kent, the wife of C. Lindsay B. Stares, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

BUCKLEY—LANYON.—On Sept. 20th, at St. Peter's, Croydon, James Charles Buckley, M.D., of Nottingham, son of the late Joseph Buckley, of Manchester, to Mabel, youngest daughter of the late John Charles Lanyon, and of Mrs. Lanyon, of "Birchurst," South Croydon.

COOKE—COOPER.—On Aug. 9th, at Ranikhet, India, Philip Geoffrey Benson Cooke, the Bedfordshire Regiment, only surviving child of John Benson Cooke, Principal Medical Officer, H.M. Convict Prison, Portland, to Mabel Sutton, only daughter of Sutton Hardwick Cooper, and of the late Mrs. Cooper.

Deaths.

BIRT.—On Sept. 19th, at Reading, Thomas Birt, Major, R.A.M.C., youngest son of the late Thomas Birt, M.D., of Leamington, aged 44 years.

MACDONALD.—On Sept. 20th, at 25 Carden Place, Aberdeen, James Macdonald, M.D., F.R.C.S.E., late H.M.I.S., in his 79th year.

NOTES AND COMMENTS.

London Practitioners and the Hospital Sunday Fund.

The Metropolitan Counties' Branch of the British Medical Association has taken a step the importance of which is obviously great. On behalf of the Branch, which comprises 2,700 London practitioners, they have presented the Lord President of His Majesty's Privy Council with a memorandum on the Petition and Draft Charter of the Metropolitan Hospital Sunday Fund. While admitting the good work done by that body, they suggest a number of points for the consideration of the Privy Council in discussing the Sunday Fund's request for incorporation. The gist of their criticism is the failure of the Fund to control the field of action of the medical charities adequately, so as to secure full benefits to the poor on the one hand and to avoid injury to members of the medical profession on the other. In many ways this document is of supreme importance, most of all perhaps in the promise of future effective organisation within our ranks. The text of this important memorandum appears in full elsewhere in our present issue.

The Examination of Midwives in Ireland.

At a recent meeting of the heads of the various Dublin Maternity Hospitals, it was decided to send a deputation to the Chief Secretary for Ireland and to point out to him the urgent necessity that exists for the holding of examinations in Ireland by the Central Midwives Board, or by an Irish Board with similar functions. At the present time Irish trained nurses who desire to register themselves under the Midwives Act are compelled to proceed to London, or some other centre in England, in order to pass their examination, and this affects very injuriously a large number of nurses who cannot afford the time or the expense for such a step. In consequence, Irish trained nurses are placed in an apparently inferior position to their English sisters, a situation which cannot be tolerated for a moment in view of the high standard of the Irish training. Two different remedies for this state of affairs have been suggested, namely, either that the Central Midwives Board should hold examinations in Dublin, or that an amending act should be passed bringing Ireland into the original act and constituting an Irish Central Board. The Central Midwives Board has already said that it is impossible for it to adopt the first course, as Ireland is outside its jurisdiction. We are not admirers either of the policy or the capacity of the Board, but we confess that in this instance we consider it to be right, and that there is no precedent for a Board, created to exercise certain functions in England, extending their operations to a country which has been deliberately and definitely excluded. Moreover, it is possible that if the Board were so to extend its functions, any nurse already registered could apply for an injunction to restrain it from swelling the numbers of registered nurses by such a course.

The Reform of the Central Midwives Board.

It is apparent, then, that if the present anomalous position of the Irish trained nurse is to be rectified—and rectified it must be—an amending act must be passed. Such an act would readily solve the Irish question, but when this has been done a more difficult task remains to be discharged. In view of the reputation of the Central Midwives Board, it is inconceivable that an amending act can be passed which does not amend the present Board out of existence. In every way that unfortunate body has proved itself unsuited for the task which it has to discharge. It has shown that it possesses no sense of the dignity and importance of its position; it has shown that it can be actuated by questionable motives, and that even when its actions have been proved by demonstration to be unwise and improper, it has an extreme reluctance to reconsider them. Further, even supposing that the existing Board had acted since its creation in a broad, generous, and capable spirit, its constitution is such as to render it wholely unsuited for controlling the training and registration of midwives in England and Wales, not to speak of the added areas in Ireland and Scotland. By all means, then, let us have an amending act which will sweep away both the Irish grievance and the present Central Midwives Board, and which will substitute for the latter either a single body representative of all parts of the United Kingdom or a separate body for each of the three kingdoms. Above all, let the act constitute an authority which will be free from that which John Knox called "the monstrous regiment of women."

LEADING ARTICLES.

CAPE COLONY AND CANCER CURING.

A GREAT many of the difficulties that arise in the dealings of this country with her colonies occur through the colonies thinking their problems out for themselves, while the mother country has traditions which are binding on her, and which she thinks should be equally binding on her colonies. Often the accumulated experience represented by these traditions is of the highest value, and again not infrequently the prepossessions engendered by them are sad stumbling-blocks. But there is a freshness of thought in the colonies which places their domestic legislation far ahead of Great Britain, and in medical matters, as a rule, their laws relating to irregular practice and their administration are infinitely more comprehensive and logical than our own. It is almost impossible to think of a quack being so persistently prosecuted by the medical authorities in this country as to be unable to ply his trade, and of him petitioning Parliament for a relaxation of the law in his favour; and it is still more difficult to conceive of his petition being regarded so seriously as for a Select Committee to be formed purposely to examine his claims. Yet what more satisfactory way could Parliament take publicly to show not only the worthlessness of a particular quack's pretensions, but incidentally to shake the public belief in the whole system of quackery? This, however, is what has just happened in Cape Colony. There was a certain Mrs. Van Niekerk in the colony who had acquired a widespread reputation in South Africa as a curer of cancer, and to her people of all stations in life either came for treatment or sent for medicine. The breaches of the medical laws she committed were such that she frequently laid herself open to prosecution, and—this is the first important point—she was frequently prosecuted; indeed, so frequently that Mrs. Van Niekerk found her life not worth living, and, backed by powerful petitions from her patients, she appealed to the Cape Government to give her leave, in the public interest, to carry on her trade. So influential was the support she obtained that a Select Committee was chosen by Parliament to investigate her claims and report on them. A thorough inquiry was held, and, as the Committee contained some members obviously predisposed in her favour, there can be no question of the impartiality of the investigation. In the first place, an official analysis of the "remedies" by which the "cures" were effected was made. These consisted of a "cancer cure"—"Aesiab," as it was called—a "blood-purifying mixture," and a "healing ointment." "Aesiab" was found to be a caustic ointment, containing 45 per cent. of tartar emetic, 5 per cent. of chalk, and 50 per cent. of lard; the "blood-purifying mixture" had as its chief ingredient potassium iodide; and the "healing ointment" consisted almost entirely of common resin ointment. Next, the woman herself turned out to be an ignorant creature, as unable to explain her "system" as to answer ordinary questions intelligently, and quite without a vestige of medical training or knowledge. Every opportunity was given her of producing patients who had been cured by the treatment, and finally four were forthcoming. These people were medically examined and reported on, and it was clearly shown that there was no evidence whatever that they had, or ever had had, malignant disease. On the other hand, information of two undoubted cases of cancer which had been under Mrs. Van Niekerk's treatment, after being "given up" by doctors, was submitted to the Committee, and in both cases it was shown not only that the patients had died more rapidly than they would have done with due care, but also that their end had been accompanied with horrible suffering. Again, this woman, who advertised the fact that she worked as a philanthropist, was found to be charging the modest sum of £1 1s. 6d. for a pot of ointment worth 6d. or 1s. at the outside, according to current trade prices. The pots of this ointment were accompanied with directions containing grossly untrue statements, such as that "ultimate cure was sure and certain," and that it obviated the "dreadful knife of surgical operation"—a particularly cruel lie, because it caused sufferers to postpone their only chance of safety till too late. Thus the Committee reported, adding that where apparent cures had been wrought the patients were syphilitics whom the "blood-purifying mixture" had benefited by virtue of the potassium iodide it contained. The treatment of cancer by caustic ointments they showed to be an antiquated and all-but-useless treatment, and quite preposterous on account of its uncertainty and barbarity. In a word, the whole business was a vulgar fraud, conducted with ignorance, cruelty, and lying; and the Committee recommended that such changes should be made in the patent laws as to prevent even apparent Government sanction of such proceedings. Mrs. Van Niekerk's petition, it was resolved, should unhesitatingly be dismissed. For an impartial Parliamentary Committee to arrive at such conclusions, after a thorough and careful inquiry, shows what the claims of quacks amount to in the eyes of men of the world when the light of investigation is turned on to them, and we would that our legislators in the old country could take a lesson from their colonial brethren. Were a Royal Commission to investigate the subject of quackery, it could only find the grossest fraud and imposture in every corner of it.

TRUTH AND QUACKERY.

IN his issue of last week, the Editor of *Truth* has favoured THE MEDICAL PRESS AND CIRCULAR with several columns of more or less pertinent comment. The cause of this remarkable outburst is a letter that appeared in our columns a few weeks ago from a correspondent writing over the name of "Obscure Practitioner." As a matter of fact, the writer in question is a well-known and responsible medical man, whose communication was spontaneous. Needless to say, in publishing his letter we by no means undertook to endorse his views. For fairly obvious reasons, *Truth* has chosen to confuse the issues by assuming that the views of an "Obscure Practitioner" are those of the Editor of the MEDICAL PRESS AND CIRCULAR. In drawing editorial attention to that letter we

expressed an opinion in mild and temperate language that *Truth* considerably weakened his position as a castigator of frauds by admitting questionable advertisements to its own columns. On the occasion of a similar criticism some months since, *Truth* favoured this journal with a furious attack couched in rhetoric of the choicest Billingsgate type. The latter-day policy of that redoubtable journal makes one regret the time when, with Mr. Labouchere at the helm, facts and arguments were marshalled with precision and coherence. *Truth's* main sarcasm last week centred on the fact that although our correspondent called "Sanatogen" objectionable, an advertisement of that product appeared in the same number. Our editorial view of Sanatogen is that it is a valuable nutrient, advocated by medical men of high standing, and that our medical readers should be informed of its claims to attention. *Truth* may be reminded that even if an objectionable advertisement should by chance slip into our columns, our readers are medical men, that is to say, they are competent to form an opinion for themselves as to the credibility of statements therein published. Our censorship, moreover, is begotten of long and close experience of medical matters. On the other hand, an advertisement appearing, say, in *Truth*, reaches many persons who are absolutely unable to exercise any judgment of the slightest value as to the advertiser's statements. For instance, the "Ganesh Strap," a leather appliance "stuffed with fragrant herbs," guaranteed to cure wrinkles, and sold at a guinea and a guinea-and-a-half apiece, has for a long period been advertised in *Truth*. As a man of the world, the Editor of *Truth* has no doubt duly weighed and assessed the credibility of such a claim before admitting the advertisement to his columns, and before he pocketed large sums of money for introducing it to the notice of his readers. We confess to some curiosity to learn how the Editor of *Truth* can justify his continued advertisement of the strap and other remedies sold under similar mysterious names, which, we assume, like the stuffing, are also of Eastern origin. In future libel actions in which *Truth* is the defendant the point may probably engage the attention of counsel, in which case it cannot be avoided by several columns of persiflage and impertinence.

NOTES ON CURRENT TOPICS.

Coroner *versus* Medical Profession.

Although the attitude of Mr. Coroner Troutbeck with regard to medical men estranges our sympathy, it is impossible to avoid a certain admiration for his sustained courage. Alone among his judicial fellows he tilts fearlessly and unceasingly against a whole profession, and like his prototype, Don Quixote, is impervious to ridicule, reason, remonstrance, or reproof. With Dr. Freyberger as henchman, he defies the profession and continues to edify the public with tit-bits of more or less elementary scientific interest. Seeing that he has deprived the general practitioners of his district of the fees to which they are entitled both by right and by usage, it is hardly to be wondered at if the spirit of revolt has rooted itself deeply in Mr. Troutbeck's district. Last week a Lambeth medical man refused to grant a death certificate, and in consequence an inquest became necessary, when the usual "expert" Dr. Freyberger, made a *post-mortem* examination whereby double pneumonia was disclosed. The Coroner thereupon delivered a jeremiad in which he lamented the fact that he had no power to compel a doctor to give evidence. An alteration of the law was in his opinion urgently needed, so that a coroner might call for that information and pay for the report. Surely Mr. Troutbeck could have called the medical man and have paid him the usual guinea—a course that would probably have been far less costly to the ratepayers than the payment of a so-called "expert." However, this superior and courageous gentleman concluded, according to the newspaper reports, that "a machinery which had never been highly tested might have done for the condition of things 60 or 80 years ago, but it was not suitable in the present condition of medical knowledge and civilisation in England, and especially in London." It is not easy to understand, if a gentleman of Dr. Freyberger's stamp be essential to the safety of Londoners, why provincials should not be equally protected. On the other hand, we quite agree with Mr. Troutbeck that a change of coroner's law is urgently desirable, chiefly with a view to counteract his own high-handed innovations, involving, as they do, a gross injustice to general practitioners.

The Vivisection Commission.

The rather belated announcement of the names of the members of the Royal Commission on Vivisection had been so much discounted by the knowledge that this, that, and the other person had consented to serve, that the full composition of the Commission did not come with the shock of surprise. To the chairman, Lord Selby, no possible objection can be taken; indeed, from every point of view his appointment is an excellent one. The medical profession is strongly and satisfactorily represented, and the anti-vivisectionists have an able spokesman or two. We are not acquainted with the opinions held by all the lay members of the Commission, but we hope there is nothing in the anti-vivisectionists' objection that they should have had a larger proportionate representation. It is desirable that the report of this Commission not only shall be authoritative, but also that it shall be the result of searching inquiry from every point of view, and for this reason it might have been better if it had been possible to arrange for the anti-vivisectionists to have had people who satisfied them—that is, if it be possible ever to satisfy anti-vivisectionists. So certain are we not only of the value of experimental research on living animals, and of the humanity and conscientiousness of the research workers, that we welcome every legitimate method of investigation into the conduct both of

experiments and experimenters; and if there be any under-representation of the anti-vivisection interest, it may probably be due to the fact that no responsible person is acceptable to all anti-vivisectionists. Indeed, so divided are these good people that they have already begun to fall foul of each other, and we are edified by seeing, in the *Tribune* of September 25, Mr. Stephen Coleridge, the champion of the weak and oppressed, fire off his big guns at—Miss Kidd, the secretary of the weakling society which tries to compete with his own.

The "Little Brown Dog."

THE excitement which the newspapers tried to raise over the "little brown dog" incident has fizzled out rather badly. There was a transparent desire on their part that there should be a demonstration, a raid by medical students, or what not, to make good copy. We sincerely trust that nothing of the kind will take place; it would only draw attention to a piece of silly bravado on behalf of the Battersea Borough Council in accepting the monument, and in the recesses of Latchmere Park the brown dog and its followers are likely to sink into obscurity. The worst policy to adopt with regard to a matter of the kind is to advertise it. It is rumoured that the Council of University College are considering the propriety of bringing an action for libel against the responsible parties, and, while it would serve them right to be made to pay heavily for their folly, it is much to be hoped that the Council will not proceed to law unless they are advised not only as to ground for action, but that there is no reasonable doubt about a favourable verdict being obtained. The sickly sensationalism of the whole business is shown by the adoption of the adjective "little" to describe the brown dog. There is an appeal to the emotions in the word "little" which the word "big" would not make. The particular dog who was "done to death" was not little. The incident upon which the case of Bayliss *versus* Coleridge was founded is, one would suppose, one that anti-vivisectionists would have liked to draw a veil over. This revival of it lends itself to such obvious comments on the ideas of honour prevailing among them that we need say nothing further on the subject.

A Fiasco and a Vindication.

A HIGHLY satisfactory ending to the "Essex Burial Mystery" has come about. The facts which came out at the coroner's inquest on September 25 were that Dr. Adams, of Buckhurst Hill, attended an elderly lady, Mrs. Oliver, with whom he was on terms of friendship, for valvular disease of the heart. This lady's brother and his wife, who apparently had "expectations," found on her death that, like many expectations in this world, they were not crowned with fulfilment. These good people were also dissatisfied with Dr. Adams, and after Mrs. Oliver's death and burial they put the reasons for this dissatisfaction so strongly that it was decided the body should be exhumed and an inquest held. Accordingly this was done, and the result was a triumphant vindication of Dr. Adams. The brother's wife had told in her affidavit of dark doings in the sick-room; of continual sickness, pains in the head, the constant changing of the medicine, the difficulty of getting Dr. Adams to give her a definite answer. Consequently a complete analysis of the viscera was made by Dr. Willcox. No trace of poison of any kind was found, while, on the other hand, Dr. F. J. Simth, who made the *post-mortem*, found valvular disease of the heart and inflammation of the right lung. As this was the condition diagnosed by Dr. Adams during life, and confirmed by Dr. Rose Bradford, who saw Mrs. Oliver in consultation, the whole "mystery" was dispelled in a moment, and the jury gave a verdict handsomely exonerating Dr. Adams from any suspicion of unprofessional conduct. We sincerely congratulate him on his success after the anxiety he must have suffered during the long time of waiting. Had the findings been, as was possible, indeterminate, the unworthy cloud of suspicion might have remained and embittered his life. As it is, his honour as a gentleman and his skill as a physician are publicly established.

Mr. George R. Sims and "Ta'cho."

IT is announced that Mr. George R. Sims is surrendering his property in a much-advertised hair nostrum into the hands of a syndicate. This step will be regarded with approval by his many admirers in the medical profession. From the scientific point of view, it is absolutely futile to claim specific powers of stimulating a growth of hair by rubbing in drugs. It is, of course, a matter of common knowledge among medical men that in the form of patchy baldness, known as alopecia areata, the hair will often grow under the influence of strong stimulation, but just as often it grows of its own accord, or remains permanently bare. Now the fame of a hair restorer not infrequently depends on its effect in patchy baldness, whereas it is almost invariably useless against ordinary baldness of the crown, whether precocious or senile. The treatment of baldness, as a matter of fact, requires technical medical skill of the highest specialised type. Under these circumstances, medically unqualified persons claiming to cure hair troubles are likely to do more harm than good. Mr. George R. Sims has won name and fame as one of the most brilliant of modern journalists, and we are glad to learn he is abandoning his excursion into alien and less reputable territory. *Ne sutor ultra crepidam.*

Rontgen Rays and Cancer.

AMONG the many points connected with cancer that await the final professional verdict, is that of the therapeutic value of the Röntgen rays in the treatment of malignant neoplasms. The question has naturally occupied a prominent position at the International Congress for Cancer Research that took place last week at Frankfurt. The result of the discussions left matters much as they have been for several years past. It appears to have been pretty generally agreed that the rays were beneficial and sometimes curative in the case of superficial growths, but even there it was doubtful if permanent improvement resulted. Dr. Schiff,

of Vienna, observed that the cure of experimentally transplanted cancers in mice was encouraging. To have gained even a partial success in the treatment of so refractory a malady is a step in advance. No one who has seen the almost magical influence of the rays in abolishing pain and reducing bulk in secondary nodules recurring after operation can doubt that the Crookes' tube exercises some powerful, if ill-understood, influence over malignant growths. If on no other ground, the therapeutic value of the rays in abolishing pain is inestimable, and there is no other way of securing pure local analgesia by narcotic drugs.

Liniment Drinking.

One of the saddest features of the appalling waste of human life around us is the fact that so many deaths are, so to speak, uncalled for and needless. Clearly, it is the work of humane and progressive legislation to reduce to the lowest possible point the preventable margin placed in the hands of the great Devastator. Possibly some day, for instance, Parliament may find time to consider ways and means of checking the steady drain upon the resources of the nation involved in the accidental drinking of poison from medicine and other bottles. Only a week ago a Cardiff woman was given by her dearest friend a dose of deadly poison in the shape of an aconite and belladonna liniment taken from a physic phial placed on the mantel-shelf, alongside another containing a pepsine preparation. Some years ago we recorded the death of a workman who drank carbolic acid by error from a lemonade bottle, an incident that actually occurred within the four walls of a leading London hospital. The moral of it all is that many deaths would be prevented were Parliament to decree that all poisons should be sold and kept in distinctively-shaped bottles. We commend this useful bit of practical social legislation to the consideration of the present energetic Home Secretary, of Mr. John Burns, or of any private member to whom the claims of the community are above those of mere party.

Post Office and Pathological Research.

The revised regulations bearing on the carriage of pathological specimens by post, while giving greater liberties than those they supersede, are yet unduly restrictive. Under the late regulations it was compulsory that all such specimens should be sent by registered letter post; the necessity for registration is now abolished, but it is provided instead that the specimens are to be "enclosed in a receptacle hermetically sealed, which receptacle must itself be placed in a strong wooden leather, or metal case." It is not every medical practitioner who has at his hand the means of hermetically sealing a package, and in many cases delay completely frustrates the purpose of the proposed examination. Again, it is provided that "the packets must on no account be sent by parcel post." This is a needlessly irritating restriction, since its purpose is by no means plain, and it is impossible to send a specimen of considerable size by letter post. It is often necessary to transmit to a laboratory a tumour or other specimen of several pounds weight, and it will be impossible under the present regulations to make use of the post for this purpose. It is, of course, quite proper that the Postmaster-General should insist on sufficient precautions being taken as regards the packing and carriage of pathological specimens to prevent injury to the other packages committed to his charge, but there is no need that the precautions should be made prohibitive. Medical practitioners, like other subjects of His Majesty, are entitled to a reasonable use of postal facilities, and we see no justification for limiting that use by vexatious and unnecessary restrictions.

PERSONAL.

Sir Frederick Treves, Lord Rector of Aberdeen University, completed his duties on Saturday, and returned to London on Monday last.

Mr. Evan Spicer, chairman of the London County Council, opened a new wing of the Convalescent Home, Limpsfield, on September 29th.

Sir William Church, Sir William Collins, Mr. Gaskell, and Dr. George Wilson are the medical members of the Royal Commission on Vivisection.

Sir Francis Laking has practically recovered from his recent severe illness, and was able to leave Aberdeen on Monday last.

It is understood that the military hospital at Portsmouth will not be transferred to the new buildings on Portsdown Hill the Alexandra Hospital) until March. The last-named hospital is now approaching completion.

Mr. Alderman Thomas Boor Crosby, M.D., was last week admitted to the office of one of the sheriffs of the City of London for the ensuing year. Dr. Crosby, who is a graduate of the University of St. Andrews, has been in practice as a medical man for 54 years. He entered the Corporation as a Common Councilman for Langbourn Ward in 1877, and was unanimously elected alderman in 1898. He is a magistrate and lieutenant of the City of London, and a Past Master of the Turners' Company.

Harvard University has conferred the degree of LL.D. upon Sir Thomas Barlow and Professor Charles S. Sherrington.

It will relieve the minds of Coroners' jurors to learn that the Public Health Committee of the Camberwell Borough Council recommend that a glass partition should be placed between the bodies deposited at the mortuary and jurors whose unpleasant duty, especially in hot weather, it is to view them. Should this common-sense idea be adopted in all large towns the finer feelings of many, to whom the process is at all times objectionable, will be greatly relieved.

A CLINICAL LECTURE
ON
DISEASES AND INJURIES TO THE ORBIT.*

By SYDNEY STEPHENSON, M.B., F.R.C.S.

Ophthalmic Surgeon to the Evelina Hospital, the North-Eastern Hospital for Children, and the Queen Charlotte's Lying-in-Hospital.

PART II.

(2) Non-inflammatory affections of the orbit may be divided into three sub-classes, viz. :—(1) Where exophthalmos exists ; (2) where enophthalmos exists ; and (3) where exophthalmos alternates with enophthalmos.

Exophthalmos or proptosis(*a*) is the word applied to indicate protrusion of the eyeball. It may result from (*a*) increase in the size of the globe or of the orbital contents generally, or (*b*) diminution in the holding capacity of the orbit. The former is a much commoner cause than the latter. The last-named, however, is strikingly exemplified in that curious affection, leontiasis ossea, where the great increase in the thickness of the bones tends to extrude the eyeball from its socket, and, even better, in the malformation of the skull known as oxycephaly. Exophthalmos is an early, almost constant, and most valuable sign of orbital tumour. It may be so slight as to be difficult of recognition, or so marked as to be visible at a glance. Small degrees can be diagnosed only when one eye is affected. The higher grades lead to several serious consequences, of which the more important are eversion of the lids, epiphora, conjunctivitis, lagophthalmos, exposure keratitis, dislocation of the eyeball, and inflammation or atrophy of the optic disc from stretching of the optic nerve. Diplopia is common, and so is limitation of the ocular movements from mechanical interference with the optic nerve and extrinsic muscles of the eyeball. In order to recognise exophthalmos, we stand behind the patient (who should be seated), raise both upper lids, and compare the summits of the corneæ with one another, and with prominent landmarks, as the eyebrows. The position of the eyeballs in the orbit is generally such that a straight edge held vertically against the upper and lower margin of the orbit does not impinge upon either eye. Nevertheless, there are many individual variations in this respect. Special instruments, such as that of Ambialet (*Recueil d'Ophtalmologie*, June, 1903) have been devised for measuring the position of the eyeball. Hertel's exophthalmometer (*Arch. f. Ophthal.*, Bd. LX., 1, 1905) is perhaps the best instrument to use for the purpose. By means of an ingenious arrangement of mirrors and scales, the actual prominence of each eyeball can be read off in millimetres. A little practice, however, is needed before the appliance can be used to the best advantage.

It is well to remember that unilateral exophthalmos always suggests an orbital tumour, while bilateral exophthalmos generally means Parry's disease—that is, exophthalmic goitre.

Enophthalmos, a rare symptom, may be seen in acute disease, as cholera, in chronic disease, as myxœdema, after traumatism, in facial hemiatrophy, and, lastly, as one of the signs of paralysis of the cervical sympathetic nerve. The palpebral fissure is narrowed, and the eyeball appears to be unduly small—sunken, like an artificial eye, as it were. The physical cause of enophthalmos may be either (*a*) enlargement of the cavity of the orbit, or (*b*) diminution of the contents of the orbit.

I.—*Exophthalmos Exists.*—Under this head we have Parry's disease, pulsating exophthalmos, orbital tumours, and exophthalmos due to blood or to air in the orbit. In the first disease sooner or later both eyes are usually involved, but in the others one eye is alone affected.

Upon examination we find that the exophthalmos is bilateral, that the thyroid gland is enlarged, and that tachycardia is present. The disease is Parry's disease, or Graves', or Basedow's disease, or exophthalmic goitre, by all of which names it is known. The patient is likely to be a young or middle-aged anæmic woman, of highly-strung temperament. Fine tremors and sleeplessness may exist, and are important diagnostic points, especially in early cases. Look for five palpebral signs, any or all of which may be present :—(1) Pigmentation of the skin of the eyelids ; (2) a disturbance of the association normally existing between the movements of the upper lid and of the eyeball, in the sense that when the patient looks downwards, the lagging upper lid exposes more or less of the conjunctiva above the cornea (von Graefe's sign) ; (3) a retraction of the upper or (more rarely) of the lower lid, the effect of which is to give the patient a peculiar, staring appearance (Dalrymple's sign) ; (4) an infrequency in the act of involuntary winking, which, instead of taking place every few seconds, may occur once a minute or even seldomer (Stellwag's sign) ; (5) a fine tremor of the closed eyelids, inappreciable to the patient (Sansom's sign). I have observed in many patients suffering from this disease a concentric contraction of the visual field for small white objects, quite similar to the contraction met with in cases of amblyopia nervosa. H. Gifford (*Ophthalmic Record*, June, 1906) has recently described in cases of exophthalmic goitre an unusual difficulty in everting the upper eyelid, not due to exophthalmos. I have not yet been fortunate enough to meet with this sign, which is believed to be due to undue irritability of the levator of the eyelid.

We find that there is unilateral exophthalmos, and that pulsation is to be felt with the fingers, and murmurs heard when the stethoscope is placed over the closed eyelids. The disease is pulsating exophthalmos. There may be pain, and patients constantly complain of "noises in the head." Enlarged and pulsating vessels are sometimes present on the surface of the eyeball. Pulsation and murmurs and noises in the head cease on compressing the carotid artery, a most important diagnostic point. Chemosis may be present. Vision may suffer from papillitis ; the retinal veins are apt to be distended. The symptoms often closely follow a severe injury to the head. The common cause of the condition is a rupture of the internal carotid artery into the cavernous sinus, and this arteriovenous anastomosis is brought about either by traumatism or else by the rupture of an aneurism.

In addition to unilateral exophthalmos, we find on palpation with the finger a swelling between the margin of the orbit and the eyeball. An orbital tumour is almost certainly present.(*a*) The cardinal signs of this rare condition are three in number :—(1) Exophthalmos ; (2) limitation of movement of the eyeball ; and (3) the existence of a palpable tumour in some part of the orbit. Ptosis also is common in tumours originating from the upper part of the orbit. Disturbances of sight are frequent, and are due to papillitis, retinal hæmorrhages, and atrophy of the

*Delivered July 18th, 1906, in the Post-Graduate Course of Ophthalmology in the University of Oxford.

(*a*) By some the word "proptosis" is applied to mean protrusion of one eye, and "exophthalmos" protrusion of both eyes.

(*a*) Certain cases of more or less chronic periostitis may closely simulate tumour.

optic disc, following interference with the optic nerve and circulatory obstructions.

The commoner tumours of the orbit include dermoid cysts, exostosis, angiomata, and sarcomata. They must be distinguished from one another by the history of the case, the age of the patient, the rate of growth, the amount of pain, the interference with function, and by a consideration of the many points that have to be thought of in tumours originating from other parts of the body. Diagnosis, indeed, may be impossible until a piece of the growth has been submitted to microscopical examination. The tumour may be primary, secondary, or metastatic. To distinguish a secondary from a primary growth, consider the surgical possibilities, and examine, as far as possible, the frontal, ethmoidal, and sphenoidal sinuses and the maxillary antrum. Never omit to investigate the condition of the teeth, fauces, nasal cavities, and posterior choanæ in every suspected tumour of the orbit. Trans-illumination may be usefully employed. Malignant neoplasms, as a rule, grow rapidly, cause much pain, and speedily interfere with the movements of the globe. The converse, of course, is true of non-malignant growths.

Tumours of the optic nerve, although extremely rare, call for a few words of separate description. They generally occur in children, and present four main peculiarities:—(1) Papillitis is an early sign and may even foreshadow proptosis; (2) exophthalmos is in the axis of the orbit—that is to say, without lateral or vertical displacement; (3) the mobility of the eye tends to remain unimpaired for a long time; (4) an antero-posterior flattening of the globe may be caused by the pressure of the tumour, and this will reveal itself to ophthalmoscopic examination by increasing hypermetropia.

Dermoid cysts may be periorbital or orbital. The former are common. The periorbital dermoid, a congenital growth liable to increase in size after birth, has its seat of election at the outer end of the eyebrow, where on account of its superficial position it does not cause proptosis. It forms a firm, hemispherical movable mass, to which the skin is not attached. When such a tumour appears at the upper and inner angle of the orbit it must be carefully distinguished from meningocele or meningo-encephalocele. The differential diagnosis is given in the following table:—

Dermoid Cyst.	*Meningocele.*
1. A hard mass not reducible by pressure, and devoid of fluctuation or translucency.	1. A softer mass, the size of which can sometimes be reduced by pressure, with or without the production of cerebral symptoms. It may be translucent and fluctuate on pulsation.
2. No pulsation.	2. May pulsate synchronously with the brain.
3. No alteration when child cries.	3. May swell on crying.
4. No communication with cervical cavity.	4. A hole in the base may now and then be felt with the finger.

Exostosis may originate either from the frontal bone or break through into the orbit from the frontal sinus. They grow exceedingly slowly, but at length cause marked proptosis, with ulceration of the cornea and loss of sight. If within reach of the finger, their osseous characters are easily determined. Examination with the X-rays should not be omitted in these cases.

Mucocele or empyæma of the frontal sinus, when pronounced, is more likely to fall under the notice of the ophthalmic surgeon than of the rhinologist. It is due to closure of the duct leading from the sinus to the nose, generally as the result of traumatism In slight cases there will be pain and tenderness when pressure is made over the upper and inner part of the orbit, and pus or granulations may be recognised on examining the nose with the mirror and speculum. In marked cases, however, secretion will accumulate in the sinus, and, finally, appear as a tumour in the orbit by distending the osseous walls of the cavity. In such a case there is a tender swelling above the tendo oculi (or farther outwards), and the eyeball may be displaced forwards, downwards, and outwards. The wall of the tumour may "crackle" under the finger, or in advanced cases it may be felt to be perforated, with a fluctuating swelling protruding to the upper part of the orbit. It is well to recall the fact that the maxillary sinus is often simultaneously diseased, so that its condition should receive attention in these cases as a matter of routine.

Unilateral exophthalmos is sometimes set up as the result of blood or air in the tissues of the orbit. Blood may be extravasated in adults as the outcome of injuries, and in children as a symptom of scurvy, and in babies from injury at birth. For the recognition of the first and last forms the history will suffice. In good-class infants under twelve months of age, who have been reared on artificial foods or sterilised or condensed milk, it is not extremely uncommon for one eye to become suddenly proptosed, and for the second eye to suffer similarly a few days later. On careful examination, we can often find some indications of hæmorrhage about the ocular conjunctiva, the eyelids, or the face. Under such circumstances a further search will probably discover sponginess and ecchymosis of the gums (present only where teeth are erupted), and painful periosteal swellings of the femur or tibia. The disease is infantile scurvy, often though incorrectly called "scurvy-rickets."

Pass the finger over the swollen eyelids, and notice whether crepitation is to be felt. In this case emphysema exists. The lids are the seat of a "cold" or non-inflammatory œdema, and there is more or less proptosis. The condition generally follows a blow, and is due to the fact that the orbital tissues have been placed in communication with some of the adjacent air sinuses by fracture of the bones and rupture of the mucous membrane.

II.—*Enophthalmos Exists.*—If the enophthalmos follows a severe local injury it is due to (1) cicatricial contraction, or (2) fracture of the walls of the orbit. The history will suffice to distinguish these somewhat rare cases of traumatic enophthalmos.

If together with enophthalmos we find the pupil of the same eye contracted, especially in dull light, we suspect paralysis of the cervical sympathetic, and look for other signs of that condition in the shape of drooping of the upper lid, unilateral absence of perspiration, and a failure of the pupil to become larger when cocaine is dropped into the eye. Search for evidences of fracture of the clavicle, operations on the neck, or enlarged cervical or thyroid glands—that is to say, some of the commoner causes of the condition. Some cases date from birth, and appear to be due to injury with forceps, as in a case reported by Reese ("New York Eye and Ear Infirmary Reports," January, 1896), who observed in a baby delivered by forceps, marked cranial deformity, narrowing of the palpebral fissure, contraction of the pupil, and enophthalmos. A few years ago a child of five years was brought to me suffering from left-sided sympathetic paralysis ("Reports of the Society for the Study of Disease in Children," Vol. III., 1903, p. 149). A puckered scab was present about one inch above the outer third of the left clavicle, immediately behind the posterior belly of the sterno-mastoid muscle. On enquiry, it was found that eighteen days previously a retro-pharyngeal abscess had been evacuated. This case has its counterpart in an earlier one reported by Schapringer (*American Journal of Ophthalmology*, October, 1893).

Enophthalmos seems to be a constant sign of myxœdema, although it is often overlooked on account of the swelling of the face.

In facial hemiatrophy the enophthalmos is believed to be due to wasting of the orbital fat.

III.—*Exophthalmos Alternates with Enophthalmos.*—In so-called intermittent exophthalmos (of which some forty cases have now been reported) the eyeball protrudes when the patient stoops down, and occupies

its normal position, or is rather sunken, when he stands up. In some instances the exophthalmos may be induced by the patient simply holding his breath, as in a case lately reported by Posey (*Journ. American Med. Association*, February 18th, 1905). The eyelid may become painful and suffused and the retinal veins enlarged and pulsating when the stooping posture is maintained. Varicose veins may be visible around the orbit or elsewhere. It is significant that pressure upon the jugular veins leads to increased protrusion of the eyeball. There is often a history of injury. These cases of intermittent exophthalmos are believed to be due to the presence of varicose veins or some other kind of vascular neoplasm in the orbit. At the same time the condition must be distinguished from retro-ocular angiomata, where the protrusion of the eyeball is constant, while pulsation may be felt with the finger and a bruit heard with the stethoscope.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by Sir Charles Ball, M.Ch., F.R.C.S., Honorary Surgeon to His Majesty the King in Ireland, Regius Professor of Surgery in the University of Dublin, Surgeon to Sir Patrick Dun's Hospital, on "The Operative Treatment of Internal Piles," with practical illustrations.*

ORIGINAL PAPERS.

THE ADULTERATION OF BUTTER

By E. W. HOPE, M.D.,
Medical Officer of Health for the City of Liverpool.

THE Sale of Food and Drugs Acts are very carefully administered in Liverpool, and the closest attention is given to the supervision of the food supply generally. There are eleven specially trained and qualified inspectors exclusively employed in these duties, and purchases under the Acts are frequently made by agents. The City Analyst, who is also an Analyst for the County, has his own laboratories for the City work. Butter is one of the most important articles of food, and owes its superiority to other fats to being more digestible, and consequently more nutritious. This explains its higher price. The amount consumed is very large, and assuming that Liverpool takes its proportion of the quantity consumed in the country in proportion to the population, it may be estimated that about 5,000 tons of butter are consumed annually in Liverpool. The value of it is about half a million sterling.

The quantity used, the ease with which adulteration can be practised, appear to have led to butter adulteration becoming a fine art, and it is a fact that certain adulterations of butter are exceedingly difficult of detection even by analysis, and it is practically impossible for the consumer to detect the fraud, owing to the ingenuity and skill of those engaged in adulterating.

The following table shows the number of samples of butter taken during each one of the last six years, together with the number of instances in which the butter was found to be adulterated :—

Year.	No. of samples of butter taken.	No. of convictions.	Amount of Penalties and Costs
			£ s. d.
1900	38	2	11 19 0
1901	94	11	28 7 0
1902	109	5	14 17 6
1903	174	17	103 1 6
1904	197	—	—
1905	254	8	23 16 6

It appears that convictions and penalties are followed by a withdrawal from the market of the adulterated articles, which are presumably sent elsewhere for a time. This result is probably due to the exposure as well as the penalty, but the offence recurs after a time. When a manufactured article is subject to extensive adulteration, the only method of effectually checking the adulteration is by supervision of the places of manufacture. It will be seen by the table that during the last five years the number of samples of butter taken for analysis in Liverpool has steadily increased, viz., from 94 in 1901, to 254 in 1905. It is quite true that the Health Committee of the City of Liverpool realises the importance of dealing with the subject, and will continue to deal with it in the interests of public health, regardless of cost; but, if cost is a consideration which a City of the size of Liverpool has to encounter, it is plain that smaller areas, with smaller funds at their disposal for the prevention of crime in regard to food adulterations, may be almost powerless.

From the standpoint of the public health administrator, the Sale of Food and Drugs Acts and the action taken under them, cannot be regarded as effectual in dealing with frauds similar to the adulteration of butter.

It may be taken for granted that the ingenuity of the adulterator is not only displayed in the methods of adulteration, but also in disposing of the adulterated articles. The procedure under the Act is costly, and may involve the purchase and analysis of many hundreds of samples before an adulterated one is found. Moreover, the vendor from whom the sample is purchased may be a perfectly innocent person. Having regard to the immense number of retail places, it is obvious that the supervision or detection of frauds at these points must be far more difficult than the supervision of the places of manufacture. A reference to the case of tea is up to a point permissible as an analogy. The examination of tea at the port of entry is a very much sounder way of protecting the public than leaving such protection to analysis of retail samples. Tea, it is true, is a non-perishable article, and a non-manufactured one, but excepting these features the analogy holds. There is even a closer analogy as regards water supply, the purity of which is primarily ensured by inspection at the source, and only very secondarily dealt with by testing at some few of the myriad points of domestic supply.

Butter, although a manufactured substance, has yet a definite natural composition, much, in fact, as milk has. The essential constituent of butter is fat, and whether it is water or salt or casein or fats other than butter that are added, they all of them are foreign to the essential constituent of butter. Unsalted butter should contain from 82 to 87 per cent. of fat, and 5 per cent. less in salted butter appears to be a fair proportion. The addition either of water, or of other fats to butter, even although they may in themselves be innocuous, are none the less fraudulent if the mixture is sold as butter, just as in the case of the addition of water to milk. The added substance in this case is not in itself harmful, but gross imposition and injury are inflicted when the mixture is sold as milk. It appears abundantly plain that with proper care and proper attention, butter need not contain more than 16 per cent. of water. The sale of butter containing a higher percentage of water should be dealt with in the same way that milk containing an excess of water is dealt with, but if the article is labelled and the purchaser duly informed, the sale would then be comparable with the sale of the mixture of coffee and chicory. The objection to milk-blended butter is not only that it contains more water, but that it decomposes more quickly, and consequently the use of antiseptics is more likely to be made.

All non-butter is margarine, and should be called margarine. The application of fancy names to adulterated or water-logged butter is highly objectionable on account of misleading the public. It must be borne in mind that vast numbers of purchasers are ignorant of all matters in connection with food supplies, and are most easily deceived by fancy

names. A remarkable instance of this within my own knowledge occurred in the case of an article sold in packets as "egg powders," made of carbonate of soda and tartrate of potash, or tartaric acid. The packets were labelled, "each packet contains the equivalent of one egg." In this case the poor woman who purchased them had actually been giving the powders to her children under the impression that it was a cheap way of giving eggs. This sufficiently illustrates the want of knowledge and thought on the part of the poorer classes.

Every place where butter is manufactured, blended, worked, treated by any process, stored, or made up for sale, should be licensed or registered, and open to inspection by the inspectors of some Government Department, such as the Board of Agriculture or the Local Government Board, and such regulations as may be found necessary should be made. It is of equally great importance that these places should be open to inspection by an officer of the local authority; this power of right of entry should extend beyond the district of the local authority, to factories, &c., in any district from which butter is sent in to the district of a local authority. There is a precedent for this in the case of tuberculous or contaminated milk. Imported pure butter is also admittedly "faked" in this country. The storing of articles simulating butter fat, capable of being used for the adulteration of butter, should be prohibited in butter factories.

The inspectors should have the power to inspect the processes, and also have power to take samples in the factory for the purpose of analysis.

Since the foregoing was written a Select Committee of the House of Commons have carefully considered the question of butter, and have tabulated their views. It would, however, be well if these suggestions were supplemented by power of entry and inspection being given to officers of local authorities as well as to those of Government Departments; moreover, it is also desirable that, in addition to the registration of premises where butter is blended, re-worked, or treated by any process, or where abnormal butter is habitually produced, places where butter is made or where butter is stored should also be registered. The necessity for this is too obvious to need comment. The recommendations of the Royal Commission are as follow:—

Recommendations.

1. That inspectors of the Board of Agriculture and Fisheries and the Department of Agriculture and Technical Instruction for Ireland should have power to enter any premises where they have reasonable grounds for believing that butter is made, blended, re-worked, treated by any process, adulterated, or stored.

2. That premises where butter is blended, or re-worked, or treated by any process, or where abnormal butter is habitually produced, shall be registered with the local authority of the district as a butter factory.

3. That no fat, other than butter fat, and no vegetable or other oils, nor any substance capable of being used as an adulterant of butter should be brought into or stored or allowed to be in any registered butter factory.

4. That no substance be added to butter whereby the percentage of moisture in the butter is increased.

5. That the addition to butter at any stage of the process of manufacture of any fat not derived from milk be expressly and directly prohibited.

6. That margarine, when sold by retail, should be handed to the purchaser in a wrapper, on which the word "Margarine" shall be printed in black, solid capital letters not less than ½-inch square, and if more than one wrapper is applied to the margarine, the word "Margarine" shall be printed as above on the inner wrapper; that no fancy name or description shall be permitted which refers to butter or anything connected with the dairy industry; that the outside wrapper, as well as the inside wrapper, should contain nothing but the word "Margarine" in type as aforesaid; and if any fancy name is printed on any other wrapper, the word "Margarine" should be suffixed or affixed to the fancy name in letters of the same size, colour, and type as those in which the fancy name is printed.

7. That no margarine made in any margarine factory shall, when the process of manufacture is complete, contain more than 16 per cent. of water, and no margarine shall be imported containing more than 16 per cent. of moisture.

8. That premises where margarine is re-worked or submitted to any process shall be registered as margarine factories.

9. That Sub-section 3 of Section 20 of the Sale of Food and Drugs Act, 1899, be amended so as to provide that a warranty or invoice given by a person resident outside the United Kingdom shall not be available as a defence to any proceedings under the Sale of Food and Drugs Acts.

10. That penalties for the importation of adulterated butter should be proportionate to the magnitude of the consignment.

11. That all practicable steps should be taken to bring about international agreements as to the prevention of adulteration.

12. That Section 4 of the Sale of Food and Drugs Act, 1899, should be amended so as to give the Board of Agriculture and Fisheries, and the Department of Agriculture and Technical Instruction for Ireland power to fix standards for curd, and to give the Local Government Board power to fix standards for preservatives.

13. That the Department of Agriculture and Technical Instruction for Ireland should have power to take proceedings under the Merchandise Marks Act.

14. That nothing shall be sold under the name of butter which contains more than 16 per cent. of moisture.

15. That substances other than butter (not being margarine) containing butter fat should be sold, with a limit of 24 per cent. of moisture, under a name approved by the Board of Agriculture and Fisheries; provided that such name should not be calculated to prejudice the sale of the article.

16. That such substances when sold by retail should be delivered to the purchaser in a wrapper, approved by the Board of Agriculture and Fisheries, containing a description of the nature, substance, and quality of the article; and as far as possible under the same conditions as apply to the sale of margarine.

17. That the provisions of the Margarine Act of 1887 as amended by the Sale of Food and Drugs Act, 1899, should apply to all such substances.

18. Inspectors acting under the special direction of the local authority should have power to enter butter factories, to inspect any process, and to take samples.

19. That butter having been treated by any process shall not be allowed to be replaced in the original packages.

A CASE OF ANKYLOSTOMIASIS (a)

By J. LLOYD ROBERTS, M.D., B.A., B.Sc.Lond., M.R.C.P.Lond., F.R.C.S.Eng.

Honorary Physician Royal Southern Hospital, Liverpool.

Ankylostomiasis, speaking broadly, is a disease of tropical and sub-tropical countries. But in this country our interest in it was greatly increased a few years back by the discovery that an epidemic of anæmia which occurred amongst Cornish miners was really the manifestation of Ankylostomiasis—the infection having been introduced into the mines by workmen who had returned infected from some Continental mining district.

Still more recently—within the last few weeks—our interest in the disease has been further

(a) Read before the Liverpool Medical Institution.

enhanced by the fact that it is expressly mentioned by name in the Workmen's Compensation Bill, now before Parliament, as a disease, the contraction of which by a workman in the course of his work renders his employer liable to the payment of compensation.

As, therefore, it is conceivable that questions as to this disease may arise in actions at law, in which we as medical men may be involved, it seemed to me not inappropriate that I should report an interesting case of this complaint which a few months ago was under my care in the Tropical Ward of the Royal Southern Hospital.

The case was interesting because the patient was a native of Liverpool, a seafaring man.

Now, considering the very extensive prevalence of ankylostomiasis in tropical countries, and the fact that British sailors and soldiers are to be found in all parts of the world, it is at first sight somewhat astonishing that the disease is not much more frequently introduced into England by these classes of men. But it, as a matter of fact, is not very surprising, as it is found by experience that infection is generally due to absolute neglect of all rules of cleanliness and decency, and that a very moderate amount of care is sufficient to guard against the disease. As confirmation of this, I may mention that in Egypt, where ankylostomiasis is most widely distributed, it is almost, if not quite, unknown amongst the English troops.

It has, however, long been known that infected persons returning home from infected districts do bring the parasites with them. In this country this, fortunately, is not a cause of much alarm, except in the case of miners. The disease has not yet been found to spread readily above Lat. 47N. (which crosses the middle of France) except in the stimulating warmth of mines, and even in them only as far North as Latitude 52°, which includes the lower fourth of England, Holland, Belgium, and Germany.

Nature of Disease.—Ankylostomiasis is a disease characterised by certain intestinal and nervous symptoms, and a gradually progressive anæmia, which may reach any degree of severity from a slight pallor to a condition of blood which in prolonged cases is irremediable and fatal.

It is caused by the introduction into the intestinal canal of the larvæ of the ankylostomum duodenale which thereupon are enabled to develop into their adult condition, and to remain as permanent parasites on their human host.

These worms are nematoid in type, and to the naked eye are not unlike the common threadworm in appearance. If these worms were present singly or in small numbers, the amount of damage would be slight, but unfortunately when infection takes place it is found that scores of larvæ are generally introduced at the same time, the result being that they may give rise to symptoms of the utmost gravity. I say *may* because it is by no means uncommon to find at autopsies in the tropics that the intestines had harboured these parasites without there having been any obvious constitutional symptoms during life.

I pass round a tube containing a bunch of adult worms which look as though they might be short bristles from a common paint-brush. During life these worms are a pale, reddish colour, but as you see them after their death they are greyish white. There is not the same disparity in size between the sexes that is usually found in parasites, the female being as usual the larger—about 12 mm long—but only exceeding the average male by about 2 mm. In both the head end is tapering, and has a circular opening leading into a concave space armed with four hard curved teeth. The concavity of the space enables the parasite to attach itself by suction to the mucous membrane of the intestine, and its hold is further strengthened by its four curved teeth. The worms are mostly found after death in the jejunum, notwithstanding their name. After attaching themselves to the mucous membrane they proceed to suck a fold of it into their mouth cavity, and this fold is gradually digested and utilised as the parasite's sustenance. It used to be thought that the creatures lived by sucking the blood of the host, and this was supposed to be the cause of the ensuing anæmia; but in all probability what the worm aims at is not blood, but an unending meal off mucous membrane. Occasionally it is true that a small artery may be opened into, and in that case blood is lost both into the cavity of the worm's body and into the host's intestine. On these occasions and at the times when the animal has digested all the membrane within its reach, and shifts to new pastures, some oozing takes place, and there is actual loss of blood to the host. These occurrences, however, are not frequent.

The method of digestion is assumed to be as follows:—

The worm is possessed of three large glands, the ducts of which open just at the root of the teeth, and it is reasonably conjectured that the secretion of one or more of these glands is injected into the fold of mucous membrane in the parasite's mouth in order to lead to its digestion and assimilation.

In all probability some of the secretion of these glands gets, at the same time, into the circulation of the host, and acting as a hæmolytic poison induces those blood changes which in their turn explain the symptoms of ankylostomiasis.

The reasons for assuming that the anæmia is induced in this way, rather than by direct loss of blood, are, firstly, that the quantity of altered blood discharged by the rectum is small out of all proportion to the anæmia; and secondly, that the anæmia is not of the hæmorrhagic, but of the chlorotic type.

The female worms, after fixing themselves, soon begin to excrete eggs in enormous numbers, and it is the discovery of the eggs in the fæces which confirms the diagnosis of ankylostomiasis. Their discovery is very easy; all that is necessary being to place a speck of the fæces, diluted if necessary with a drop of water, on a slide, to cover it with a cover-glass, and to examine it with the low objective of the microscope. The ova are large, and easily recognised. They are clear and transparent at the periphery, whereas nearly all other intestinal ova are dark and bile-stained. They are oval in shape, measuring on an average about 60 μ by 40 μ. They have a delicate transparent shell, through which two or four, or more, yolk-segments can be easily seen when the eggs are passed out of the bowel.

The ova develop quickly after excretion. If the fæces be kept in a warm room for 24 or 48 hours, and then examined, many of the ova will be seen filled by coiled-up embryos. The latter go through several stages of development during the first week, but after that pass into a dormant

condition, in which they may remain alive for many weeks or months in damp earth. If during this period they are by any means, such as unwashed vegetables, or the muddy hands of the miner or agriculturist, or the food of the geophagist introduced into the human body, they find their way again into the intestine, develop into the adult form of the worm, and commence the cycle over again.

Till latterly this method of infection (by means of food) was supposed to be the only one. It is probably the most common method, but within the last few years Professor Loos, first by accident and afterwards by experiment, demonstrated another possible mode of infection. He proved that the larvæ, if brought in water into contact with the human skin, have the power of penetrating through it, and of reaching by a marvellously ingenious route their ultimate goal in the duodenum and jejunum.

It has been shown by experiments that the larvæ reach the cutis vera through the hair follicles, and then penetrate into either a capillary or a lymph-vessel. Carried by the stream in either of these vessels, they ultimately reach the right side of the heart and later the pulmonary capillaries. Here they leave the blood vessels and bore their way into the air cells, from which they travel upwards through the bronchial capillaries, the bronchi, the trachea, and larynx till they reach the pharynx, from which their passage into the stomach is simple.

It is possible that in my patient the larvæ found an entry into his system in this manner. One evening while trying to return to his ship at Pernambuco, very intoxicated, he dropped to the ground, and lay all night on his right side on the wet, earthy sand. The next day his body and the outer part of the thigh on the right side were red and inflamed, and dotted with innumerable red spots which were very itchy and smarting. This is similar to the result which follows when larvæ are experimentally placed upon the skin.

Some days later he was seized while at work with sudden giddiness and diarrhœa. The latter continued off and on till admission, accompanied by abdominal and epigastric pain. He described the stools as having been liquid, jet black in colour, and at times slimy. With reference to this history it may be remarked that giddiness and epigastric pain or discomfort are very common early symptoms of ankylostomiasis. Diarrhœa, however, is not usually present, and the passage of tarry stools is very rare. If in this instance they are to be ascribed to the infection, it suggests that the number of larvæ which had penetrated the patient's system was unusually large, and produced considerable intestinal congestion and irritation.

The patient was admitted into hospital, complaining of diarrhœa, on May 22nd of last year. He was debilitated, very anæmic in appearance, and had a dull, heavy facial aspect. It is interesting to note that this combination of debility, anæmia, and stupidity of expression is frequently found in patients suffering from ankylostomiasis.

His appetite was unusually good, and had been throughout his illness—another characteristic of the subjects of this disease, in all but the very latest stages.

Two days after admission he informed us that he had passed per rectum a small worm which he described as white, thin, slightly twisted, and about one-eighth of an inch long; and also said that he had passed two similar worms during the fortnight prior to entering the hospital. Threadworms and ankylostomes are somewhat similar in appearance, but as it is extremely rare for the latter to travel down to the anus I concluded that he was suffering from threadworms. I accordingly ordered him a dose of santonin, which, however, did not lead to the expulsion of any worms.

As the diarrhœa persisted in spite of treatment, on June 1st the fæces were examined microscopically, and were found to contain numerous ankylostome eggs. This discovery settled the diagnosis and was a sufficient explanation of the patient's various symptoms.

During the following ten days the patient suffered much pain from the development of an ischio-rectal abscess, which was incised with much relief to him on June 10th. This is not a recognised complication of ankylostomiasis, because the worms are rarely found in the rectum, and it is open to question whether in this case it can be ascribed to the irritation caused by the worms, but their unusual presence in the rectum of this patient makes such a suggestion feasible. The suppuration and pain considerably lowered the patient's strength and increased his anæmia.

During the development of the abscess after consultation with Professor Ross, it was not deemed desirable to commence the specific treatment of the disease by anthelminthics on account of their depressing properties.

With regard to treatment, Dr. Sandwith, who has had enormous experience of ankylostomiasis in Egypt, after prolonged trial of male fern, B. naphthol, and other anthelminthics which at various times have been vaunted as the best remedy for the ankylostomes, has expressed the opinion that it is waste of time to try any other anthelminthic than thymol, which appears to be a specific against the worms. But to be effective very large doses—enormously larger than the pharmacopœal maximum of 2 grains—must be employed. And the use of such large doses requires special precautions to be taken. In some persons the drug produces somewhat dangerous collapse and the effect of the first dose should be carefully observed. Fortunately it is very insoluble in the human stomach, and it is this insolubility which renders it safe to administer such large doses, while leaving the drug free to exert its topical effect on the parasites. It must be remembered in this connection that thymol is soluble in alcohol, ether, chloroform, and oils, and that therefore none of these must be given to the patient either shortly before or after the drug. Serious accidents have happened through neglect of this precaution. If patients show any signs of collapse after their first dose of thymol, they must be stimulated *not* by alcohol, but by strychnine subcutaneously, or hot coffee per rectum. The contra-indications to the use of thymol in Dr. Sandwith's opinion are excessive debility, age above 60, very low temperature, and advanced disease of heart or any other organ. It is necessary that the patient should be kept in bed for some hours after taking the medicine, and that a full dose of sulphate of magnesia or castor oil should be given two hours after the thymol, in order to drive it out of the bowels as soon as it has served its purpose.

There are several ways in which the drug may be administered.

1.—Keep the patient in bed for a day or two on low diet, and let the bowels be cleared out by an aperient. In the morning give three or four doses of 15–25 grains of thymol at intervals of one hour, and follow them with a purge. In some cases one such course is sufficient to expel all the ankylostomes, but if ova continue to appear, one or more subsequent courses may be given at intervals of six or seven days.

2.—Keep the patient in bed all one day on milk diet, and without a preceding aperient give 15 grains of thymol in the evening. Repeat the same dose early the following morning, give an ounce of sulphate of magnesia two hours later, and keep the patient in bed the second day. Three or four such courses are the average number required for cure.

3.—Give a daily morning dose of 15 to 20 grains of thymol, followed by an aperient, till ova cease to appear.

As soon as the condition of my patient permitted, I commenced with the thymol treatment, and to gauge his power of taking it, I gave 10½ grains on the mornings of June 15th and 17th. Finding that it was well borne I gave him on the morning of the 20th four hourly doses of 15 grains. But the result was unsatisfactory, and the ova continued as numerous as before.

The course was repeated a few days later, but again without success as on the 27th the ova were still very numerous, and apparently not diminished in numbers.

The general condition of the patient was gradually getting worse, and by this time examination of the blood showed that the number of red corpuscles was reduced to 1,644,000 per c.m., and he complained more and more of palpitation and dyspnœa, which became alarmingly severe. The number of leucocytes, as is usual in this disease, was slightly increased, being 13,100 per c.m.; and a differential count showed that the proportion of eosinophiles was as high as 47 per cent. Eosinophilia is characteristic of the disease, but is not of much value in diagnosis, as it occurs in infections due to many other parasites. Its continuance, however, in a case of uncomplicated ankylostomiasis during treatment is of importance in that it indicates that the patient is still harbouring some of the worms.

The urgency of the patient's condition demanded that a fresh attempt should be made to destroy the parasites which seemed so resistant to treatment. Rather than try another anthelminthic we determined to administer the thymol according to the third manner described above. Twenty grains were given each morning, and after five days there seemed a slight diminution in the number of ova in the fæces. As the patient was bearing the drug well, the daily dose was increased to 30 grains. One week later the ova were few in number, and in still another week had quite ceased to be excreted.

During this time, with the help of an iron mixture the patient rapidly improved, the anæmia disappearing and his strength returning.

He was kept under observation for nine days longer, but no more ova were found in the fæces, and he was discharged feeling well and strong.

[Since this paper was read the patient presented himself again after an interval of nine months at the hospital, complaining of debility and palpitation. He had felt quite well for about eight months, spending the time partly at sea, and partly on shore as a dock labourer. During the ninth month he had not felt well, and he was getting weaker. He was also somewhat anæmic. Fearing that he was suffering from a recurrence of the disease I admitted him into the ward, and found upon examination of the fæces that such was the case. The ova were much fewer in number than on the first occasion, but it was clear that he had not completely got rid of his parasites. It was evident that the fact that no ova had been seen, even after fairly careful observation, for nine days was not sufficient to prove that the patient was cured.

On this second occasion I administered the thymol according to the second method described in the paper, which is the routine method at the Kasr-el-Ainy Hospital. But although the patient had several courses the ova did not cease to be excreted. I accordingly returned to the method of daily morning dose, and after some time the fæces were again found to be free from eggs. I kept him under observation till the fæces had been free for over a fortnight, and he was then discharged apparently cured.

This recurrence, however, shows the necessity of great caution in pronouncing a patient cured.]

CEREBRO-SPINAL MENINGITIS. (a)

BY PROF. JUDICE CABRAL, M.D.,
Of the Faculty of Medicine of Lagos.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

EPIDEMIC cerebro-spinal meningitis is now generally recognised and described as an infectious disease due to the presence of the *diplococcus intracellularis* discovered by Weichselbaum. Other organisms, it is true, may give rise to inflammation of the cerebro-spinal meninges, but not to epidemic meningitis, properly so-called.

The precise mode of invasion of the organism is still enveloped in obscurity, and we are reduced to more or less plausible conjectures. Some observers believe that the organism enters *via* the respiratory tract, while others hold that the alimentary tract provides the open door, digestive disturbances, which, it must be admitted, often precede meningitis, being a predisposing cause. The most generally received opinion is in favour of the organism finding its way into the body through the nasal mucosa, the meningococcus entering the cranium through the cribriform process of the ethmoid along the lymphatic vessels of the pituitary membrane.

Dr. Westenhoffer not long since suggested that the germs were propagated by the nutrient vessels that traverse the sphenoid, admitting, nevertheless, that the organism may start from the middle ear along the carotico-tympanic canaliculi. This observer, however, holds that the meningococcus never takes the ethmoid route.

The contagiousness of epidemic cerebro-spinal meningitis is one of the most debated points in the etiology of this disease, and the pathologists who refuse to admit it are more numerous than those who accept this view. Personally, basing our conclusion on facts observed in the course of the epidemic at Algarva, we hold that every individual suffering from meningitis consti-

(a) Abstract of Paper read before the Fifteenth International Congress of Medicine, held at Lisbon, April, 1906.

tutes a focus of infection, whether the propagation takes place by direct contact or by the intermediary of contaminated linen, etc.

In the majority of cases the attack of meningitis sets in suddenly, the subject having previously been in excellent health. The symptoms which form the classical tripod of the onset are shivering, headache, and vomiting. In certain exceptional cases prodromal symptoms have been observed, such, for instance, as general prostration, with tingling or pain in the lower limbs, intestinal colic or gastro-enteritis. It is especially in cases where the meningitis is principally spinal that we get the gradual onset with motor and sensory disturbances.

The sudden onset is almost always followed by a short period of remission, during which the initial symptoms subside, or give place to torpor. This period, which lasts a few hours, occurs on the second day, or, it may be, on the evening of the first day. Soon the vomiting ceases, but the temperature is more or less raised. Symptoms of motor and sensory stimulation make their appearance: convulsions, contractures, opisthotonos, delirium, restlessness, and insomnia dominate the clinical picture. There is obstinate constipation, and the tongue is dry and sticky. Anorexia and thirst complete the list of digestive disturbances. This state lasts for a week or so, gradually subsiding in mild cases, or the symptoms may suddenly disappear altogether from one day to another.

Death occurs in 40 per cent. of the cases and the immediate cause of death varies according to the particular form of the disease. In hyperacute cases, in which the disease runs its course in a few hours, and in which the organism is, so to speak, overwhelmed by the violence of the attack, death takes place in coma. In the convulsive forms death is due to asphyxia, caused by tetanisation of the diaphragm and immobilisation of the thorax. Not infrequently, however, nutritive perversions of the nerve centres, determined by the meningeal inflammation, bring about the bulbar syndroma in which death supervenes. In some cases enfeeblement of the myocardium, with pulmonary congestion and œdema, constitutes the terminal accidents. In other cases death is precipitated by œdema of the glottis. Myocarditis, general asthenia, collapse, coma, bed sores, and inanition are the causes of death in the chronic cases.

In spite of its diversity of forms and symptoms, the diagnosis of epidemic cerebro-spinal meningitis is usually fairly easy. The acute onset and the uniformity of the phenomena by which this onset is ushered in (headache, vomiting, and rigors), the prompt supervention of spinal pain, of rigidity of the neck, of opisthotonos, the appearance of labial herpes and Kernig's sign, only to mention the commoner symptoms, prevent our mistaking it for any other disease, especially when meningitis is epidemic at the time.

In sporadic cases, however, the diagnosis may present considerable difficulty. It is especially with typhoid fever that confusion is likely to arise, either because the typhoid fever, especially in its ataxic form, is associated with grave symptoms involving the nerve centres, or because the meningitis, departing from its usual form, by its onset, by the temperature curves, by the presence of gastro-intestinal complications, and by its general course, may present appearances not at all unlike that of enteric fever. We must seek the differential diagnosis in sero-reaction on the one hand and in lumber puncture on the other.

Another affection with which the disease has often been confounded is miliary tuberculosis. Here again the bacteriological and cytological examination of the cerebro-spinal fluid should put us on the right track.

The diagnosis between epidemic cerebro-spinal and other forms of meningitis, especially tuberculous meningitis, often presents grave difficulty. Certain it is that in most instances tuberculous meningitis is preceded by prodromata, while in epidemic cerebro-spinal meningitis the onset is, as a rule, very sudden. There are exceptions to this rule, for tuberculous meningitis has been known to supervene suddenly, and epidemic cerebro-spinal meningitis may, in rare instances, be preceded by prodromal signs.

There are still two important factors to be considered in arriving at the diagnosis—viz.: the cytological examination of the cerebro-spinal fluid and cultures of this fluid in gelose-blood. Cytological examination of the figured elements obtained by centrifugation of the fluid enables us to recognise the presence of an excess of polynuclear leucocytes in cases of acute meningitis, meningococcal or otherwise, as well as the predominance of lymphocytes in tuberculous meningitis. Attention must however be called to a possible source of error when the fluid has been withdrawn during a period of remission, for in such event the lymphocytes predominate over the other forms.

The prognosis in epidemic cerebro-spinal meningitis is always grave, although the gravity varies from one epidemic to another, and even in the same epidemic. Our statistics for 1901, with 151 cases, give a mortality of 41.30 per cent. In 1902 the epidemic, which was beginning to decline, gave us only 26 cases, but the mortality was much greater than the previous year, viz., 57.6 per cent.

The gravity of the attack is dependent upon the severity of the inaugural nervous symptoms, to the violence and duration of the delirium and convulsions, and to the degree of fever.

In the matter of treatment various antispasmodics and narcotics have been tried, along with derivatives and counter-irritants, alterative and antipyretic drugs and nerve sedatives, invariably with absolutely negative results from a curative point of view, and very mediocre results even as palliatives.

We have never seen any beneficial results follow the use of hot baths, the questionable efficacy of the baths not compensating by any means the extreme suffering to which they give rise, in view of the extraordinarily hyperæsthetic state of the patient. Local blood-letting, when resorted to at the onset in the form of leeches over the mastoid process, and wet cupping along the spinal column, has been followed by a very pronounced amelioration and sound refreshing sleep for some hours. Counter-irritants over the dorsal region, repeated at intervals of several days, appear to be of some service. With regard to internal medication, calomel, opium and the bromides are the only drugs that yield any tangible result. Our experience leads us to regard the administration of copious enemata (a quart) of boiled water, plain or mixed with substances exerting a slightly purgative action, as beneficial in nearly all cases.

A telegram to the *Matin* from Lyons confirms the existence of leprosy in the Swiss village of Guitet. Suspected cases are also reported from Feigel, in the neighbourhood of Guitet. A young man in an advanced stage of the disease died on the 15th ult.

THE OUT-PATIENTS' ROOM.

GREAT NORTHERN HOSPITAL.

Injury to Pelvis.

BY PEYTON BEALE, F.R.C.S.

MR. BEALE was asked to see, on behalf of his colleague Mr. Mower White, a boy, æt. about 5, who had been run over by a dray and brought to the surgery a few minutes previously. It appeared that the wheel of the dray had passed obliquely across the lower part of the abdomen, but beyond this no evidence as to the accident was obtainable. The patient was suffering intensely from shock, and on placing the hand over the region of the symphysis pubis, the latter could not be felt at all. There was rather copious hæmorrhage from the rectum, and so it was deemed advisable to examine under an anæsthetic. When the boy was under chloroform the rectum was examined, and a very large rent was found in its anterior wall; the finger passed through this, and could be felt beneath the abdominal wall, but no trace of the symphysis pubis could be found. As the whole of the space between the rectum and the anterior abdominal wall was full of fæcal matter, an incision was made between the recti and over the region where the symphysis pubis should have been. This incision exposed a large cavity full of blood-clot and fæces, and on further exploration it was seen that the two pubic bones had been separated at the symphysis, and that they were four inches apart. A rubber catheter was passed into the bladder without difficulty, and it was at once evident that both the whole length of the urethra and the bladder had entirely escaped injury. The pelvis was examined carefully, but no fracture could be found on either side, though the sacro-iliac joints were somewhat movable. It therefore seemed clear that the wheel had passed from above downwards over the abdomen, and had split the symphysis pubis. Mr. Beale could only assume that the boy's rectum had been quite full of fæces, and that its anterior wall had ruptured under the pressure of the wheel. The two pubic bones were brought together and sutured with silver wire, the cavity of the pelvis was thoroughly washed out with hot lotion, so as to clear away all the blood and fæces, and large gauze drains were inserted in the rectum and in the abdominal incision. The patient was at once taken into the ward. Mr. Beale said that the most difficult point to explain was the rupture of the anterior wall of the rectum. He had seen some cases of fractured pelvis in which the descending ramus of the pubis had been broken and forced downwards into the rectum, its jagged end being felt on a rectal examination being made; but in the present case the rent was a very large one—at least three inches long—and there was apparently no fracture of either ramus of the pubis or of the ischium. He had never before seen any case like it, nor could he realise how a wheel passing over the pelvis could inflict such an injury. At the same time, he could not realise how such conditions could be found and at the same time how the urethra and bladder could have escaped injury. In the second place, he could not realise had mostly been caused by the patient being crushed by the tailboard of a cart pinning him against a wall. Some were caused by the patient being run over, and one, the most serious he had seen, and which he had reported some years ago, was caused by the passage of one of the hind wheels of a steam-roller over a man's pelvis.

OPERATING THEATRES.

EALING COTTAGE HOSPITAL.

ABDOMINAL PREGNANCY.—MR. PEYTON BEALE (in Mr. Carless' absence), operated on a woman æt. about 30, who had been admitted with intense abdominal pain and high temperature. Nothing characteristic could be made out about the onset of the symptoms. She noticed the pain in the abdomen some two days previously about the region of the umbilicus, and it had gradually become more severe up to the time of admission. There was no distension of the abdomen, but it was intensely tender all over on deep pressure. There was a little fluid in both flanks. Urine was passed normally. The bowels had been opened freely. The uterus on examination was larger than normal, and slightly fixed. An incision was made in the middle line of the abdomen below the umbilicus. It was at once evident that there was diffuse general peritonitis, and on investigation this was found to be most acute in the region of the fundus of the uterus. Here the small intestines were coated with thick yellow lymph, various coils being adherent to one another. The appendix, ovaries, and Fallopian tubes were all normal, but attached to the left side of the uterus was a spherical soft tumour about three inches in diameter, and it was quite obvious that from this the general peritonitis had emanated. This tumour was gradually brought into view at the abdominal incision, and it was then seen that blood-stained serous fluid was escaping through a small opening in it. During the attempt to get a clear view of it, it broke away from the uterus, and was easily removed with the hand. It was then found to be a cyst-like structure, containing some blood-clot, and it was evidently an abdominal gestation, probably of about a month's duration; its contents had an unpleasant odour, but this was not fæcal. The difficulty was to account for the general peritonitis; but the assumption was that the infection spread from the cyst, as this was obviously the region where the peritonitis was most intense. As much of the lymph as possible was peeled off the intestine, and the abdominal cavity rapidly washed out with hot sterile salt solution. The abdominal wound was closed, a gauze drain being left at its lower end. Mr. Beale said that he assumed that this was primarily a tubal gestation which had passed into the abdominal cavity. He had not previously seen a case of this kind, although he had operated upon many ruptured tubal gestations; in the latter cases there was practically no general peritonitis, and they all occurred at a later stage of pregnancy, so that the chief symptoms were a large amount of blood free in the abdominal cavity, the patient suffering from collapse as the result of the hæmorrhage. In the present case he did not think the cyst had ruptured through any visible aperture before he had handled it, and noting the absence of any marked inflammation about the openings of either of the Fallopian tubes he was at a loss to account for the very acute peritonitis which was present.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 30th, 1906.

A NEW DIPLOMA.

A new diploma has been instituted in France, styled Certificate of Superior Medical Studies, and takes a place between the usual M.D. and the Fellowship. Only those possessing the M.D. are admitted to the examination, which is written and oral.

The written portion comprises a composition in anatomy, histology, and pathology, while the oral embraces general pathology. If the candidate has

passed these preliminaries, he undergoes an examination in practical pathological anatomy, comprising the different methods of exploring the tissues and morbid tumours.

The jury is composed of nine members taken from the professors of medical faculties. The examinations will be held twice a year, the first to take place in October of next year.

The new diploma will be required of all assistant professors in the Universities.

A Sign of Arterio-Sclerosis.

Attention has been drawn to a sign of arterio-sclerosis which seems to dispel all doubt on the affection. It is called the palmar sign, as it is observed in the palmar arch of the hands. By pressing on the radial artery so as to stop the pulse, those patients suffering from arterio-sclerosis, and especially from aortic insufficiency, feel in the palm of the hand a slight sensation which they compare to the prick of a pin, or the walking of a fly. Out of twenty-four subjects thus examined, in only four was the sign absent. Seven of the twenty suffered from aortic insufficiency. In healthy persons this sign could not be produced.

The explanation of the phenomenon would appear to be that by the compression of the radial artery the cubital artery is congested, and this fact, with the contraction of the hypertophied ventricle, increases the speed of the blood current, increasing in this way the intensity of the shock in the palmar arch. Naturally, the sclerosed condition of the arteries contributes to the production of this sign.

Treatment of Eczema According to the Region.

The treatment of eczema varies according to whether it is local or general. Besides the general treatment, which consists in tonics, arsenic, cod liver oil, and dietary régime, the local treatment might be as follows:—

Scalp.—The first indication is to remove the crusts after cutting the hair as close as possible. This is effected by compresses of boiled water and covered with oil silk, or the application of pure vaseline. Unctions with oil or the warm spray should only be used in women, who should in no case be deprived of their hair.

Once the scalp is well cleaned off, cod oil should be employed:—

Cod oil	5 drachms.
Oil of sweet almonds ...	3 ounces.

This composition is suitable also to eczema of the beard and eyebrows. If it prove inefficient, the following ointment might be prescribed:—

Oxide of zinc	1 drachm.
Calomel	½ drachm.
Vaseline	1 ounce.

Sycosiform eczema of the beard is more rapidly improved by sprays of warm boric acid solution or compresses of

Sulphate of copper	15 grains.
Sulphate of zinc	1 drachm.
Camphor	10 grains.
Water	12 ounces.

or a solution of resorcine (1—100). At night calomel ointment might be applied.

Eczema of the nasal fossæ.—Wash and clean the parts and introduce into the cavities plugs of cotton coated with an ointment of calomel, tannin, or oxide of zinc at 1—10.

Lips.—Very difficult to cure. Apply each night a band of caoutchouc, and during the day an astringent lotion of tannin (1—30), followed by zinc ointment.

Eyelids.—Apply emollient compresses and treat the conjunctivitis by astringent instillations of

Burnt alum	2 grains.
Water	3 drachms.

At night:—

Yellow oxide of mercury ...	6 grains.
Vaseline	1 ounce.

Ear.—Long and tedious to cure. After reducing the inflammation by the usual moist compresses, apply cod oil.

Anus.—Same treatment. If any fissures exist, they should be cauterised. The itching will be best treated by warm lotions of chloral (5—1,000) or phenic acid (1—100), or menthol as ointment.

Scrotum.—Poultices of starch or potato-flour and an ointment of

Dermatol	1 drachm.
Oxide of zinc	1 drachm.
Lanoline	4 drachms.
Vaseline	4 drachms.

Vulva.—Very tenacious, and is the cause of perpetual torment to patients on account of the pruritus accompanying the eczema. Apply moist compresses, ointments of calomel, oxide of zinc, dermatol, and chloral lotions for the itching.

Lower limbs.—Rest, and later on:—

Cod oil	2 drachms.
Oxide of zinc	3 drachms.
Vaseline	6 drachms.

Horny Eczema of the Hands and Feet.—Soften the parts with an alcoholic solution of soft soap, and apply pure cod oil or an ointment of salicylic acid (1—20).

The same treatment for eczema of the nails.

GERMANY.

Berlin, Sept. 20th, 1906.

A paper on

Vegetable Diet,

by Dr. Staehlin, Basel, appears in the *Korr-Bl. f. Sch.-Aerzte.* From his investigations he draws the conclusion that the flesh extractives (which we are only incompletely acquainted with) possess a diuretic action, and that similar material must be contained in eggs. They not only increase the elimination of water, but also of chloride of sodium. In regard to the mechanism of this we know that it partly takes place through lessened giving-off of watery vapour. From some experiments, however, we must conclude that the body may, under some circumstances, become poor with water. This perhaps explains why persons who are nourished almost exclusively on potatoes frequently have a puffed-out appearance. This diuretic property of meat extractives must depend on a direct action on the kidneys, as the circulation is so little affected by a meat diet. One might think that the kidney parenchyma was directly irritated, and this irritation may, under certain circumstances, be injurious. The same thing seems to be said as to eggs, that have the same diuretic properties, and that in large quantities are injurious to the kidneys. We know too little, however, in regard to the mechanism of kidney secretion to be able to make any positive statement. On the other hand, we see from the experiments that there is no sense in forbidding the flesh of warm-blooded animals in kidney diseases, and allowing fish. It has also been proved that the distinction between dark and white meats has absolutely no foundation. Fish has no less effect on the kidneys than beef, but, on the contrary, a greater.

The results are a warning as to allowing meat in chronic kidney disease. Meat demands more work from the kidneys. In chronic disease the organ may be unable to dispose of certain solid material, and especially urea and sodium chloride, and here one sees that meat must be injurious. In milk-feeding the small excretion of chlorine is very advantageous; on the other hand, a good deal of solid material and much water must be excreted. We might, therefore, consider a vegetable diet in kidney diseases more than we have done, but we must not forget, however, that under careful clinical observation meat has not shown itself so injurious as was at one time believed, and that the raising of the general condition would in many patients be prevented by a too one-sided diet.

On the diminished requirements for water in vegetable diet depends what has been frequently observed in the Basel Bürgerhospital, viz., when the diet is a vegetable one, the alcohol habit is much more easily treated than when meat is allowed. The author believes that one must gain the impression that vege-

tarianism is not only a fact, but that physicians must see in it an enrichment from methods of treatment. It is true, however, that much work will be required before we have thoroughly defined the limit of its indications.

MORPHIA IN ACUTE ŒDEMA OF THE LUNGS.

The *Deutsch. Med. Zeit.* has a reference (September 20th) to a paper on the subject by Dr. C. J. Ellefsen. It is known that, as a rule, where respiration is affected, morphia is looked upon by the majority of medical men with suspicion, and certainly as something more likely to do harm than good. Acute œdema of the lungs, as usually met with in elderly people with stenosis of their coronary arteries, or of the aorta, is in more cases treated with excitants, in some cases with venesection, or with sodium or potassium iodide. Concerning morphia, in steno-cardiac attacks it is almost indispensable; the general consensus of opinion is that when the stenocardia causes over-fulness in the lesser circulation and in the pulmonary capillaries, morphia is out of place. Huchard characterises it as useless and dangerous in such conditions.

That the categorical judgment is not always the correct one is beyond doubt, and every experienced practitioner will freely confess that when an effect has to be produced rapidly, and it must especially be so in these threatening conditions, when a quietening effect must be produced on the heart, so that it may do its work calmly and with greater effect, morphia is a valuable and a more reliable remedy than the newer ones: caffeine, theobromine, spanteine, and the like. A case of œdema of the lungs—with very threatening symptoms—treated recently has strengthened this conception anew.

A labourer, aged 50, who, considering his years, had a very marked arterio-sclerosis, came under treatment about a year ago with periodical stenocardiac attacks, with the usual symtoms of violent palpitation, irregular, very frequent, barely palpable pulse, etc. The attacks always came on at night.

Morphia in doses of 1 to 1½ cgm. was given, and after the attacks digitalis and sodi-iodide. The morphia always relieved the attacks, and then gradually diminished in frequency, and then ceased. In the intervals between the attacks albumen occasionally appeared in the urine. About the middle of February, some days after an attack, the patient had an attack of right-sided cerebral apoplexy, with complete loss of consciousness. The patient lay six days in a state of coma, and for days had Cheyne-Stokes respiration.

Contrary to all expectations he recovered consciousness, the paralytic symptoms of the left side disappeared rather quickly, and the general condition improved, until on March 19th, in the night, he had another stenocardiac attack. Considering his weakened condition after the apoplexy, the medical attendant was afraid to give him the morphia that had always been so useful before, and ordered caffeino-sodium benzoiceine in the usual doses, but it was quite useless, the weak, irregular pulse was barely to be counted. Mucous râles developed all over the lungs, with bloody expectoration and unceasing cough, along with all the signs of approaching collapse, cyanosis, cold extremities. Consciousness was clear.

1 cgm. of morphia was now ordered, and half an hour later another ¾ cgm., with the result that the tormenting cough ceased, and also the cardiac restlessness. The pulse improved, became slower—84—and regular. He slept for several hours. Some expectoration of bloody mucous continued still for several weeks, until the alveoli and bronchi had got rid of all the blood that had been poured into them, but the general condition of the patient improved rapidly otherwise.

Such an action of morphia under similar circumstances is certainly not unknown, but the case belongs to the rarities when all the other circumstances are taken into consideration, and one must agree that morphia proved efficacious as compared with the useless and ineffective caffeine.

AUSTRIA.

Vienna, Sept. 30th, 1906.

GUN-SHOT WOUND.

VITEK, at the Prague meeting, exhibited a young man from whom he had removed a bullet which had penetrated the muscles of the neck, lodging in the spine, about the third cervical vertebra. This was followed with a temporary paresis of the right hand, and atrophy of the flexors of both hand and arm. The ulnar and median nerves were entire, hence the trophic root of those nerves was the only destruction done which has lately been designated "Klumpke's root paralysis." There was no disturbance of the sensibility, neither oculopupillary changes.

CHRONIC PROGRESSIVE MUSCULAR ATROPHY.

He also showed a man, æt. 24, who in his childhood had suffered from acute poliomyelitis. A few years after recovery, chronic progressive muscular atrophy commenced, with atrophic paresis in the muscles of the sound side—fibrillary contractions, degenerative reaction, and loss of sensibility. It would appear that the poliomyelitis in the anterior horn, when a child, was the cause of this later development of the chronic process.

TETANUS.

Vanysek showed an interesting case of a boy, æt. 6, who got one of his toes injured with a stone. The toe healed up, but on the ninth day his jaws became locked and on the eleventh all the muscles of the body were rigid. The most peculiar point in the case was the irregular contractions in the calf of both legs, which gave the feet every appearance of *pes equinus*. This condition lingered long before it disappeared.

DERMATITIS EXFOLIATIVA.

Samberger brought forward a female, æt. 55, who had suffered from a severe attack of dermatitis, which commenced with a pustular eruption and lasted for one and a half years. The body was red and infiltrated with hyper-keratotic deposits *de capite ad calcem*.

RAYNAUD'S DISEASE.

Pelnàck demonstrated on a female, æt. 34, a typical form of local asphyxia, which now goes by the name of Raynaud's disease, who described it in 1862. No cause can be assigned in this case for the origin of the disease, and its ætiology is equally obscure. The fingers were symmetrically gangrenous. Before the disease appeared she seems to have had a good deal of nervous disturbance in the shape of neurotic œdema, paræsthesia and "local syncope." Sodii salicylate and warm baths hastened the separation of the gangrenous substance with subsequent healing.

CLIMACTERIC NEUROSIS.

He gave the history of another case where the female had been emasculated about the age of 31 years. Immediately after the operation of castration, neurotic symptoms set in which have increased to the climacteric period. Every drug in the Pharmacopœia was tried, but without relief. Rushing of blood to the head and hands, paræsthesia in the right leg producing a kind of *Claudicatia intermittens* and somnolence; a continuous sleep lasting from one to five days at a time, and frequent polyuria.

ORAL TUBERCULOSIS.

No fixed channel for the introduction of tubercle can be determined—alimentary canal or air passages. Hlava records the case of a dead child in whose mouth he found the tubercular microbe, with swelling of the submaxillary glands resembling a lymphoma. There was also swelling of the tonsils resembling tubercular hyperplasia. There were also lymphoma in the neck and infiltration in the larynx.

ALKALINE BUTTERMILK.

Moll praises the use of alkaline buttermilk, which can be had dry or in powder, in the case of weak children, or in those cases where mothers have insufficient food. In all gastric diseases it is invaluable.

HUNGARY.

Budapest, Sept. 30th, 1906.

At the recent meeting of the Interhospital Medical Association, Dr. Hann gave an excellent summary of the views held at the present day of

Tuberculosis and Pregnancy.

He also reported five cases which came under his own observation. He regarded pregnancy as a severe complication in tuberculosis, the severity of which increases with each pregnancy. Important among the prophylactic measures should be the prevention of conception among tuberculous women. If pregnancy has taken place the woman should be kept under careful medical observation, and if the tuberculous disease grows worse, abortion should be strongly recommended. During the later months of pregnancy the induction of premature labour does not offer any advantages over labour at full term, and is fraught with serious consequences for a tuberculous patient. Moreover, as a tuberculous mother may give birth to a healthy child with fair chances of good health later on, it would be unfair to needlessly sacrifice the life of the infant. Dr. Hann does not believe in universally interrupting the pregnancy as advocated by Maragliano, of Hamburg.

Dr. Temesváry read a very interesting paper on

The Blood and Urine in Eclampsia.

For the purpose of deciding whether eclampsia is a consequence of insufficient renal activity, and can therefore be ascribed to a uræmic intoxication, he carried on investigations. An explanation of this should be secured from examinations of both blood and urine. Before any opinion can be expressed on abnormal conditions, it is necessary to be acquainted with the normal relations of blood and urine as found in healthy pregnant women. The same author has already shown that the physiological composition of blood and urine in pregnancy varies considerably from the non-pregnant state. From an examination of a large number of specimens of the blood taken from eclamptic cases, he did not find any points upon which the uræmic etiology of the diseases can be based. There is a diminution in the alkalinity of the blood, and at times an increased molecular concentration, together with a larger amount of crystalloidal nitrogenous bodies; but these must be considered as an accompaniment of the diminished diuresis, which is usually present during the course of the disease. The factors just enumerated are subject to greater variations in the blood of eclampsia patients than otherwise. The most noteworthy appearance in eclamptic blood is the extreme variation in the quantity of red cells to the quantity of the blood plasma. The blood contains on an average a larger number of red cells, and, in fact, may be compared to "a paste of corpuscles." The rapid disappearance, and even more so, the rapid formation of this condition, shows that the cause of this phenomenon is not to be found in an overproduction of these elements. The proliferation itself does not represent the cause of eclampsia, as it is absent in many instances. Nor does it result from the attacks, as it may appear without any seizures having been present. The only way in which the phenomenon can be explained is that during the course of the disease severe circulatory disturbances occur, as a result of which a considerable amount of plasma leaves the blood. Concerning the urine of normal pregnancy, the author has shown that during twenty-four hours the ammonia salts are slightly increased, and the chlorides are about the same as in the non-pregnant woman. The phosphates are, as is well-known, decreased in amount, this being ascribed to the fœtal bone formation. During labour it was found that less water and salts were excreted by the kidneys than during the period immediately preceding. Especially is the excretion of chlorides diminished; that of the phosphates and ammonia salts is less marked. A very complete series of analyses was then made of the urine of numerous cases of eclampsia. These do not admit of being abstracted, and the results obtained do not lend themselves to an explanation of the manner in which the irritation of the vasomotor centres is produced. Whether this is due to toxic conditions or to a reflex nervous disturbance is therefore still a matter of doubt as far as the author's findings are concerned. If one has to do with a toxæmia, it may be stated with considerable certainty that the poison does not result from insufficiency of the renal function, nor does it leave the body through the kidneys, unless in an entirely changed form a considerable time after the disease has subsided. In other words, for the eliminaton, or, more properly, the destruction of this hypothetical toxin, the renal function is not called into play. The poison, moreover, does not bring about any increase in the molecular concentration of the blood. The changes found in the body in an eclampsia case may also be accounted for without the intermedium of a poison. Dr. Temesváry brings forward the following facts as against the idea that a toxin is present. The earlier the course of the pregnancy or the later in the puerperium the attack comes on, the more severe it is apt to be, and it is more apt to occur with the first labour pains than after these have been present for some time and have produced a toxin or thrown the same into circulation. Although there may be some basis in fact for assuming the toxic theory, the author is inclined to the belief that this is questionable, and that later investigations will show that the eclamptic attack is brought about in some other way, possibly as purely reflex nervous phenomenon.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

ABERDEEN.

THE QUATER-CENTENARY OF ABERDEEN UNIVERSITY.

The celebration of the Quater-Centenary of Aberdeen University last week proved a most brilliant affair. On Tuesday the 25th September the proceedings began with a reception of 3,000 delegates from universities in all parts of the world. A striking feature was a procession of graduates and undergraduates, who marched from Marischal College to the Strathcona Hall. Among the graduates were Lord Strathcona (Chancellor of the University), Sir Frederick Treves (Lord Rector), Lord Aberdeen, the Archbishop of Canterbury, the Right Hon. Mr. Bryce, and Mr. Andrew Carnegie. A short address of welcome was given by Principal Lane to the delegates, who then formally presented their addresses. In the evening a banquet was given by the Corporation to 500 guests, and a torchlight procession was held by the students. On the 26th the honorary degree of LL.D. was conferred on nearly 200 persons, including 150 of the foreign delegates. The Prince of Monaco headed the list, while among those who followed him were the Archbishop of Canterbury, the Bishop of Ripon, Lord Alverstone, Lord Balfour of Burleigh, Mr. Carnegie, the Earl of Elgin, and the following members of the medical profession: Dr. Herbert Mackay Ellis (Directortor General of the Naval Medical Service), Dr. Ferdinand Hueppe (Professor of Hygiene, Prague), Dr. Howard A. Kelly (Professor of Gynæcology, Johns Hopkins University, Baltimore, U.S.A.), Surg. General Sir Alfred Keogh, K.C.B. (Director General Army Medical Service), Sir Francis Laking, Bart., G.C.V.O. (Physician to H.M. the King and the Prince of Wales), Dr. Oscar Liebreich (Professor of Pharmacology, Berlin), Dr. Donald Macalister (President of the General Medical Council), Mr. Edmund Owen (Vice-president of the Royal College of Surgeons of England and Consulting Surgeon of St. Mary's Hospital, Paddington), Rev. Geo. E. Post (Professor of Surgery in the Johanite Hospital, Beirut), Sir Richard Douglas Powell, Bart., K.C.V.O. (President of the Royal College of Physicians of London), Major Ronald Ross, C.B., F.R.S. (Professor of Tropical Medicine in the University of Liverpool), Dr. Frederick Trendelenberg (Professor of Surgery in the University of

Leipzig), Sir William Turner, K.C.B., F.R.S. (Principal of the University of Edinburgh), Dr. J. William White (Professor of Surgery, Pennsylvania University), Sir John Williams, Bart., K.C.V.O. (Late Professor of Midwifery, University College, London). Sir Francis Laking, not having recovered from his recent illness, was carried to the platform in an invalid chair. On the 27th ult. the central event of the celebration took place in the opening of Marischal College. The King and Queen on that day paid a State visit to Aberdeen to open the new buildings at Marischal College. Reaching Aberdeen a quarter of an hour after midday their Majesties were received by Lord Provost Lyon and the magistrates. The Lord Provost having tendered to the King the keys of the city, which he returned, the procession moved off to Marischal College, through streets magnificently decorated and thronged with people.

The Chancellor, Rector, and Principal received their Majesties. King Edward was in Field-Marshal's uniform, and wore the dark green ribbon and insignia of a Knight of the Thistle. Lord Aberdeen, too, displayed on his Lord-Lieutenant's uniform the Order of the Thistle. Principal Lang first read an address.

KING EDWARD thanked them heartily for their cordial welcome, and the Chancellor then presented a gold and jewelled key to his Majesty, who declared the new buildings open.

A pleasing incident followed. Robert Munro, on crutches, of Muirton of Dalvey, in Morayshire, was led in and presented with the Albert Medal for gallantry in endeavouring to save life on the railway at Brodie. He was lamed for life in the attempt. The King pinned the medal on Munro's breast, shook hands with him, and said some kind words of sympathy and commendation.

Their Majesties then inspected a part of the buildings, afterwards driving to the City Chambers, where an address was presented from the Corporation.

In the evening a monster banquet was given by Lord Strathcona, the guests numbering 2,400.

The following letter has been since received by Sir Alexander Lyon, Lord Provost of Aberdeen, from the Right Hon. John Sinclair, Secretary for Scotland:—

"Balmoral Castle, September 27th, 1906.

"Dear Lord Provost,—I am commanded by the King to convey to you the expression of their Majesties' pleasure at their reception to-day by the citizens of Aberdeen. It has given their Majesties great satisfaction to have paid this visit at a moment of much importance in the history of the University of which Aberdeen is so justly proud. The arrangements were well planned and well carried out. The beauty and profusion of the decorations were strikingly effective, and their Majesties were deeply gratified by the loyalty and enthusiasm of the people. Long and familiar associations enshrine the affectionate regard in which their Majesties hold Aberdeenshire and all its interests, and they will cherish a vivid and lasting recollection of the hearty welcome given to them to-day by the city of Aberdeen.—I am, dear Lord Provost, your faithful and obedient servant, JOHN SINCLAIR."

BELFAST.

SANITARY QUESTIONS IN THE CITY.—A public meeting of citizens was held in the Ulster Hall, Belfast, on Thursday evening last, with the object of considering the health of the city, the present outbreak of typhoid, and the action of the Corporation regarding the appointment of a medical superintendent officer of health. About 1,500 persons were present, and the platform was occupied by a number of the most prominent and respected professional and business men. The chair was occupied by Mr. Robert Thompson, J.P., who briefly explained the objects of the meeting, and a series of resolutions was passed practically unanimously. The first stated in general terms that the health of the city was unsatisfactory, and demanded attention. The second was more particular, and ran as follows:—"That the action of the Corporation in fixing the salary to be paid to the new superintendent officer of health at £600 per annum, notwithstanding the repeated recommendations of their own Health Committee, of the Local Government Board, and of the citizens, as also the refusal of the Corporation to make previous experience a condition of the appointment, is unsatisfactory, and the remuneration offered is inadequate." In moving this resolution, Mr. John Sinclair made a good point in comparing the action of the Corporation in this question with their action in appointing a coroner a short time ago. So little was medical knowledge required for this post, that it was frequently filled by a member of the legal profession. Yet they had appointed a medical man at £650 per annum, allowing him to do private practice, which might bring him in as much more. And now they required a skilled medical specialist to devote his whole time to the work, they offered him £600 per annum!

The third resolution called attention to the incident reported in these columns last week, concerning the advertisements for the post not being properly published, and the fourth resolution was to the effect that these resolutions should be widely published, that a deputation should appear before the Corporation on October 1st (the day fixed for making the appointment), to ask that the matter be postponed for further consideration, and, failing this, to take such steps as may be necessary to apply for a Royal Commission of Inquiry into all matters pertaining to the public health of the city of Belfast.

The day after this meeting the Corporation met in Committee to consider the applications which have been received for the post of medical officer of health, and to reduce the number of candidates to six, to appear at the final selection on Monday, October 1st. There were sixteen applications in all, thirteen of them being English or Scotch, and three local. The six chosen on the short list are as follows:—

Dr. George Sampson Moore, Huddersfield; Dr. W. H. Bailie, Belfast; Dr. J. H. Coutts, Blackpool; Dr. Charles O'Neill, Belfast; Dr. James Beatty, Northampton; Dr. Alex. Robb, Paisley.

The local candidates are both general practitioners in the city, Dr. Bailie having been till a few months ago a member of the Corporation. The other four are all specialists in sanitary and public health work. The interest taken by the general public is very marked, as it is recognised that it is a fight to the finish between a party of builders and property-owners, hitherto all-powerful in the Corporation, and a "municipal purity and efficiency party," which has sprung into existence lately.

As we go to press we learn that Dr. W. H. Bailie has been elected.

LETTERS TO THE EDITOR.

THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "An Obscure Practitioner," appears to me in danger of taking a distorted or exaggerated view of statistics. He writes as follows in your issue September 19th:—"Sir Crichton Browne very wisely laid great stress upon the statistics lately prepared by Mr. David Heron. These statistics prove that the declining birth-rate is most evident amongst the classes having real claim to the designation 'well-bred,' whilst the physically, morally, and socially lower classes are reproducing themselves with the greatest rapidity."

I apprehend, therefore, that to make this sweeping statement of true significance, it would be necessary to prove what is not quite apparent to my way of thinking, and that is that the "physically and morally" weaker members of the British Empire are multiplying nowadays in a greater proportion to the rest of the whole community than they were before the decline of the birth-rate. If this is the case, it goes without saying that racial deterioration has already set in. Indeed, to quote the article in the *Times*, September 14:—"Sir James declares that if we are recruiting our population

from the poorer and mentally and physically feebler stocks of the community at a greater rate than from the better and more capable stocks, then gradual deterioration of the race is inevitable"; the article adding, on its own account—"The proposition is almost a self-evident one." If, then, this state of things is really taking place, criminal statistics and the Registrar-General's death returns will, I presume, ere long offer some evidence on the question. In the meantime, it seems to me that we have no right to infer that because those of a lower social grade are multiplying at a greater rate than heretofore, therefore they necessarily produce proportionately and more unhealthy stock.

I mention this point because I note your correspondent refers to the designation "well-bred." I scarcely need remind him—at least, I take it so—that as far as the maintenance and integrity of the State are concerned, social status has little to do with the question of racial deterioration. It matters not from what social grade of the community the population are recruited, provided always they are begotten from healthy progenitors, healthy, morally and physically. Provided, therefore, the agricultural labourer produce as healthy offspring as the nobleman or any other, both are equal for racial advantages. Indeed, it may be, for aught we know, to the advantage of a civilised nation in periods of its history that an excessive preponderance of its births should devolve upon its more humble yet hardy denizens, so as to counteract the *ennui* arising from the excessive luxury and indulgence of its more affluent members, which in the past have usually preceded the decay of nations. On the other hand, I should be glad if your correspondent could refer me to any historian who has shown that a declining birth-rate has been the cause *per se* (other factors being favourable) of a nation's downfall. Public opinion, I believe, regards a declining birth-rate at the present congested state of our country somewhat analogous to what our profession regards veneseotion in a plethoric state of the system—that is, a means of warding off worse conditions. Whether, however, excessive luxury or a declining birth-rate will more speedily enfeeble a nation is questionable. Common-sense, however, seems to suggest that a nation multiplying at a greater rate than either the State or its individual members can make provision for, is about equivalent in "the struggle for existence" to the augmentation of troops in warfare without food, raiment or shelter.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, September 27th, 1906.

OBITUARY.

WILLIAM WYLLIE, M.D. (GLAS.).

DR. WYLLIE, of Kirkby Lonsdale, died suddenly on September 9th, shortly after being knocked down at a pony race. Dr. Wyllie was born in 1845, at Gourock, where his father was in practice as a medical man. He graduated at Glasgow University, where he took his M.D. After qualifying, he made several voyages as ship's doctor. In 1873 he purchased the Kirkby Lonsdale practice of Dr. David Page, who was the county medical officer. In 1879, Dr. Wyllie became medical officer to the Kirkby Lonsdale Local Board, a position which he continued to hold under the Urban District Council, and which he filled to the time of his death. For 32 years he had been medical officer for the Kirkby Lonsdale District of the Kendal Union, succeeding Dr. Whittaker in this capacity, and he was also medical officer for a portion of the Lunesdale Union. He was for 33 years medical attendant for the local Rechabites and had been doctor to the Oddfellows and Druids' clubs for 25 years, being also vice-president of the widows' and orphans' fund of the Loyal Lonsdale Lodge of Oddfellows. He was a keen supporter of friendly societies, and had endeared himself to the members of many households. As a medical practitioner he was highly respected and esteemed. He was of a kindly disposition, and he took a close interest in the welfare of his patients.

DR. J. E. NEILD, OF MELBOURNE.

IT is not often that medicine and the drama go hand in hand, but by the death of Dr. J. E. Neild, Melbourne has lost its leading dramatic critic. His journalistic connection with the theatre began sixty years ago, when he was a medical student in London. For fifty years Dr. Neild's dramatic criticisms carried great weight with the play-going public in Australia. Simultaneously he carried on a large medical practice, edited the *Australian Medical Journal*, and lectured to the medical students of Melbourne University.

WHITLEY BLAND STOKES, M.A., M.D., R.U.I., F.R.C.S. (ENG.).

THE death is announced of Dr. Whitley Bland Stokes, of Onslow Square, South Kensington. He was a Fellow of the Royal College of Surgeons, Ireland, and took his M.D. degree in Dublin in 1895. He became a member of the Royal College of Physicians, London, in 1895, and a Fellow of the Royal College of Surgeons, England, in 1899. Deceased served in the Army Medical Service, in which he attained the rank of Surgeon-Captain. He filled various posts, among them that of Medical Registrar at St. George's Hospital.

ROBERT S. STEWART, M.D. (GLAS.), OF BRIDGEND.

WE regret to announce the death, on the 28th ult., of Dr. R. S. Stewart, medical superintendent of the County Asylum at Bridgend, Glamorganshire. Deceased was educated medically at the University of Glasgow, where he took the degree of M.B. and of M.D. with honours, in 1883 and 1886 respectively. His appointment to the Glamorganshire County Asylum dates only from three years ago. His contributions to the literature of insanity were numerous and valuable, and some of them dealt with the wider relations of mental pathology to the outside community. The cause of death was heart disease.

SPECIAL ARTICLE.

THE METROPOLITAN HOSPITAL SUNDAY FUND AND THE BRITISH MEDICAL ASSOCIATION.

MEMORANDUM on the Petition and Draft Charter of the Metropolitan Hospital Sunday Fund adopted by the Council of the Metropolitan Counties Branch of the British Medical Association at a Meeting held on September 25th, 1906, and submitted on behalf of the Metropolitan Counties Branch of the British Medical Association to the Lord President of His Majesty's Privy Council on September 29th, 1906.

With reference to the Petition of the Council of the Metropolitan Hospital Sunday Fund, praying His Majesty for the Grant of a Royal Charter of Incorporation, we, the undersigned, in the name of and for, and on behalf of the Metropolitan Counties Branch of the British Medical Association, comprising 2,700 medical practitioners resident in London, believing that we represent the views of the great majority of the medical profession within the Metropolitan area, beg most humbly to submit the following points in relation to the Charter in question, namely:—

I. That the Metropolitan Hospital Sunday Fund, by its power of determining the conditions upon which contributions to hospitals should be granted, exercises a controlling influence upon the administration of London Hospitals, and the Petition for a Charter by that Fund is therefore a matter of deep concern to the whole of the medical profession, not only to those

practitioners who staff the various Hospitals, but also to those who are not so attached.

II. That it has not been sufficiently recognised that Hospitals depend for their existence probably as much upon the gratuitous services of members of the medical profession as upon the monetary gifts of the charitable public, and that all medical practitioners, even those not on the staff of any Hospital, are therefore deeply interested in the administration of Hospitals.

III. That the constitution of the Metropolitan Hospital Sunday Fund fails to provide for any representation, in its Council and in its Committee of Distribution, of medical practitioners, who could best guide it in dealing with the medical requirements of Hospitals, and that the public interest thereby suffers.

IV. That while admitting cordially the beneficent work carried out by the Metropolitan Hospital Sunday Fund in many respects, we are constrained to recognise that this Fund, as almoners of money collected by public subscriptions, has failed to exercise as much influence as might have been expected in removing such serious defects in our Hospital system as are submitted below, viz. :—

(1) That the out-patient departments of London Hospitals, as at present conducted, have a pauperising effect on the patients, through the indiscriminate treatment of applicants whose cases are more suited for reference either to provident dispensaries, or to private practitioners, or to the Poor Law, and that the treatment in out-patient departments of cases that present themselves is frequently ineffective owing to the large numbers of such patients and the absence of that home supervision which many of the cases require.

(2) That the small payments exacted from patients in several Hospitals in London which are subsidised by the Metropolitan Hospital Sunday Fund undoubtedly augment the moral injury to patients by creating a false idea that sufficient payment is being made, and are more unfair to private practitioners and provident dispensaries in the neighbourhood of such Hospitals than absolutely gratuitous attendance. It must be understood, however, that this does not apply to cottage Hospitals where payments for maintenance are made and patients treated by their own medical attendants.

(3) That in our opinion the out-patient departments should only be used for important and selected cases referred for consultation by private practitioners or provident dispensaries, and thus centres of clinical interest would be created to the great advantage of scientific medicine and surgery and the improvement of material for clinical teaching.

(4) That the casualty departments of General Hospitals are especially abused by the admission of trivial cases of accident and sudden illness which might quite well be treated elsewhere, and, while we perfectly recognise the necessity of supplying first-aid without question to really urgent cases, there is, in our opinion, no justification for the very large numbers who obtain gratuitous treatment in the casualty departments of such hospitals.

(5) That while regarding the employment of trained almoners in all departments of Hospitals as indispensable, we are of opinion that subscribers' letters should be abolished, and, so far at least as clinical suitability for Hospital treatment is concerned, medical practitioners should alone recommend.

(6) That the existing efforts to promote forethought, thrift, and independence among the working classes by means of provident dispensaries would, in our opinion, be more successful if the competition of out-patient departments and free dispensaries were removed.

(7) That many of the out-patients of Hospitals belong to the destitute class, who are fit subjects for treatment under the Poor Law, apart from economical considerations, as it is not so much the mere administration of physic as food and other comforts which they require.

(8) That the Hospitals to a great extent compete with and encroach on the field of work and limit the experience of medical practitioners by undertaking cases which are neither clinically nor financially suited for hospital treatment, to the ultimate detriment of public interests.

V. That the co-ordination and co-operation of Hospitals and other medical charities, and of members of the medical profession practising in the Metropolis, are especially necessary in the Metropolitan area for the removal of the abuses which we have noted, and in our opinion an important step towards this would be attained by securing the adequate representation of the medical profession upon the council of the Hospital Sunday Fund as constituted in the proposed charter.

We would, therefore, humbly pray that all the matters set forth in this memorandum may receive favourable consideration, and to this end we crave that His Majesty may be pleased to withhold his sanction to the grant of the proposed Royal Charter of Incorporation to the Metropolitan Hospital Sunday Fund in its present form.

Signed, on behalf of the Metropolitan Counties Branch of the British Medical Association, and by order of the Council of the said branch, by

HUGH R. KER, F.R.C.S. Edin. (President of the Metropolitan Counties Branch, British Medical Association).

J. FORD ANDERSON, M.D. (Chairman of the Medical Charities Committee of the Metropolitan Counties Branch, British Medical Association).

September 29th, 1906.

REVIEWS OF BOOKS.

ORGANOTHERAPY.

THIS voume is apparently the first of a contemplated series of works, intended to uphold the general principles of organotherapy, and to place that method of treatment on a thoroughly scientific basis. Judging from the present book, the authors are determined to spare no pains in making their exposition complete down to the smallest details, and, from their method of writing, are evidently masters, in every sense of the word, of their subject. After a brief historical introduction, the "objects of a rational organotherapy" are discussed at length, and stress is laid upon the importance of only employing the isolated active principles of the various organs concerned, instead of, as till the last few years has been customary, emulsions, infusions, and extracts of the entire organs. That it is now possible to obtain the active substances in a pure form has been demonstrated in the case of adrenalin and spermin at least, and there is considerable hope that similar success will be met with in the case of other glands. The action of these active principles is regarded as a process of katalysis, analogous in almost every way to ordinary ferment action, except that in the case of the two substances mentioned the action is a general one on oxidation, instead of being limited and specific. In the same chapter an account is given of the methods at present in use of estimating the energy of body metabolism. This is principally determined by means of Poehl's urosemiological co-efficient, which is in brief the expression of the ratio between the total nitrogen excreted in the urine and the nitrogen excreted in the form of urea. Great stress is laid upon this co-efficient and on other quantitative urinary determinations, and the value of various remedies is judged largely by the influence exerted by them on this metabolic factor. The entire chapter is written in a rather controversial style, and has

(a) "Rational Organotherapy." By Prof. A. von Poehl, Prof. Prince von Tarchanoff, Dr. Alf. Poehl, and Dr. Wachs. Translated from the Russian. Vol. I. London: J. and A. Churchill. 1906.

probably not gained in clearness in the process of translation. It will certainly appeal more to the physiological chemist than to the practising and practical physician. The remainder of the book, about three-quarters, is devoted solely to a description of and discussion of the value of spermin, and also to the methods of administration and indications for its use. Spermin can now be isolated from many tissues of the body and from the blood, although, of course, its main depository within the body appears to be the sexual glands. When administered hypodermically or by the mouth or rectum, it is claimed to exert an important influence on the oxidative processes of the body, as shown by the great increase of urea nitrogen in proportion to the total urinary nitrogen. Animal experiments also seemed to show that the substance possesses powerful nerve tonic properties, and that it may be capable of increasing the resistance power of the body to bacterial disease. These observations, of course, require ample confirmation before they can be accepted, but, on the whole, we are favourably impressed with the statements made and with the proofs given. Less stress can be laid on the clinical cases quoted, though the authors have certainly been indefatigable in their use and study of the remedy in very numerous morbid conditions. They consider it of special value in neurasthenic and anæmic conditions, both of which are characterised by deficient oxidation.

On the whole, we can recommend the work to those who are specially interested in the subject, but the general practitioner will find little to attract him in its pages. As an example of the present advanced position of Russian medicine, the book possesses a special interest.

THE SHIP-SURGEON'S HANDBOOK. (*a*)

This excellent little manual, concise and compact in form, lucid in style, eminently practical throughout, is written by one who has learned to mark and digest the relations of man and medicine as manifest in deep waters. In supplying such a handbook for sea-going medical officers Mr. Elder has earned lasting thanks. Many a recently-qualified man finds himself at sea, figuratively as well as literally, when he attempts to practise the healing art in marine quarters; but this little volume, with its far-seeing and sometimes humorous hints, its suggestions and directions, and common-sense guidance as to treatment, will save from much discomfiture and will smooth what must at the best of times be a position requiring not only knowledge of medicine but acquaintance with men, tact and sagacity, patience and perseverance, discretion and courage. The volume is full of information on the choice of a ship, selection of outfit, duties on board, details as to practice, and emergency appliances.

There is a very interesting and valuable section on sea-sickness, a perusal of which might benefit all sea-going travellers. In addition to all kinds of details of a most practical character there is a very useful list of steamship lines, giving addresses of head-offices, routes, and particulars as to the surgeon's remuneration. We have no hesitation in very warmly commending this admirable little guide, which we venture to think will become an authoritative handbook for all ship's surgeons.

CATARRHAL FEVERS. (*b*)

Much of this monograph on the philosophy and pathology of "the common cold" is reprinted from the *Lancet* and other medical periodicals, but Dr. Prosser White has such definite views on his subject, and expresses them so attractively, that his little work needs no justification. The questions raised open extensive matters for discussion, and we regret that the author, while ably presenting his own views, should not have more fully dealt with the work and opinions of other investigators who have preceded him along the same path of research. After describing the familiar clinical characteristics of "a common cold," the author passes to a consideration of the bacteriology of the affection, and details his own experiments on animals, which are, however, far from convincing, and we venture to think only have indirect bearing on the apparently similar pathological condition when originating "idiopathically" in man. As far as Dr. White's researches go, they seem to substantiate the conclusions of Dr. Edmund Cantley and Dr. M. H. Gordon, and go to show that the Bacillus coryzos segmentosus is capable of producing what we know clinically as "a cold." In the concluding section of the monograph there are many practical suggestions bearing on the prevention and treatment of "catarrhs" which, whatever views we may hold as to the pathology of the condition, will be fruitful in good works so far as the patient is concerned. The volume is a suggestive contribution to a peculiarly perplexing problem.

APPENDICITIS. (*a*)

Among the many excellent works dealing with the vagaries of the vestigial cœcal appendix, which recent years have brought to us, Mr. Lockwood's monograph is destined to occupy a high place as a contribution of permanent value and lasting interest. The work is of special importance in being mainly a record of personal observation and experience, and no mere repetition of the confusing chorus of irresponsible self-selected investigators. The practical and thoroughly serviceable character of the first edition of this work is too well known to need description here, and in the present edition the general plan and arrangement is retained. New observations and new micro-photographs have been added, and the work now contains clinical records of 112 cases and an interesting tabular summary of 200 cases. The work is one which must appeal to both operative surgeons and general practitioners, and the latter will be particularly interested in the concluding chapter on "The After-Treatment of Appendectomy." The volume is excellently printed, beautifully illustrated, and there is a very helpful index.

FIBROID TUMOURS. (*b*)

This work is dedicated to "Suffering women and their responsible advisers." Its preface gives us to understand that it represents a paper which was refused publication by the "British Medical Journal," and by ourselves. So far as we can understand, the reason alleged for its refusal was that the book stated that the risks of operation for fibro-myoma of the uterus are "on the average more than five hundred times greater than those of non-operation." The first line of the text of the book is as follows:—"For the benefit of the non-medical reader . . . it will be desirous to explain some technical terms." The book closes with a glossary of medical terms, in which such words as abdomen, anus, ovary, are defined.

Dr. Shaw has not only furnished us with abundant reasons for refusing to review his book, on the ground that it is a quasi-medical work written, not for the medical profession, but for the public, but he has also given us cause to ask under what rules of medical ethics he considers himself entitled to publish a work which is calculated to cause him "to obtain practice by unworthy means."

We regret to see on the title page that Dr. Shaw is a Fellow (late vice-president) of the British Gynæcological Society.

MEDICAL NEWS IN BRIEF.

The International Congress for Cancer Research.

THE first International Congress for Cancer Research was, on the 26th inst., formally opened at Heidelberg by the Grand Duke and Duchess of Baden in the presence of numerous medical and municipal representatives from all parts of the world. At the same time a new hospital and laboratory for cancer investigations was opened. The institution has already cost over £40,000, derived partly from public and partly from private sources. The hospital contains fifty beds, sixteen for paying patients, but the laboratories are still incomplete. Papers were afterwards read by Professors von Leyden, on "The Problem of the Curative Treatment of Cancer," Czerny, on "Unexpected Recovery from Cancer," and others. A formal reception in the Town Hall, at which the Grand Duke and Grand Duchess presided, followed by illumination of the Neckar, closed the day's proceedings. Over 400 invitations were sent out to cancer specialists throughout the world by the central committee. Amongst the English representatives present were Dr. Bashford, of the Imperial Cancer Research Fund, Dr. Lazarus-Barlow, of Middlesex Hospital, the entire medical staff of the Cancer Hospital, London, and Dr. Powell White, of Manchester. The Grand Duke and Grand Duchess received all the English representatives most graciously. The Grand Duchess referred to Miss Florence Nightingale and to the indebtedness of Germany to England in nursing and hospital matters.

Opening of the Main Drainage Works in Dublin.

ON the 24th ultimo, the long expected opening of the new main drainage works for the City of Dublin took place in the presence of a large assemblage of prominent Dublin citizens and others. The works, which have occupied more than ten years in their construction, cost over half a million, and will result in an enormous benefit to the entire city. The Chairman of the Committee, to which the task of supervision of the works belonged, in the course of an interesting speech, referred to the method adopted of dealing with the crude sewage. As many of our readers know, the harbour attached to the old Pigeon House Fort which formerly guarded the mouth of the Liffey, but which has now been converted into an electric lighting station, has been altered into a series of precipitation tanks for the reception of the crude sewage. The fluid portion of this sewage is then run off as an almost clear liquid, and, purified by the lime with which it has been treated, is run into the Liffey, while the more solid sludge is carried off through culverts lying below the tanks into a storage chamber from which it is pumped into a sludge steamer specially built for its removal. It is then carried out to sea. As yet it is too soon to appreciate the effect of the new system on the Liffey itself, as there are still several sewers discharging crude sewage into it, and as the low water in the river prevents the bed from receiving a much-needed flushing. With the closage of the last contributory drain, and the advent of a few heavy winter floods, a great change may be expected, and it is hoped that the river will once again return to a normal state.

Metropolitan Hospital Statistics.

STATISTICS showing in some measure the magnitude of the work carried on by the hospital dispensaries, etc., of London have been published by the Distribution Committee of the Hospital Saturday Fund in the fund's September circular, and issued to the collectors in the various contributing workshops and business houses with the October to December collection sheets. The tables have been prepared from the returns received from 152 institutions. They represent the work of these medical charities during 1905. For example, according to the "Summary," the total number of beds at thirty-one general hospitals was 5,748; the average number of beds occupied, 4,795; total number of in-patients, 74,172; total number of separate out-patients; 542,229; total number of separate casualty cases, 584,719; total number of home visits, 55,695; payments made by in-patients, £8,143; payments made by out-patients, £4,941; net income from investments, £143,349; total cost of maintenance, £502,352; total cost of management, £38,063. At the London Hospital, according to the detailed tables, during the past year of the total number of beds—933—at that institution the average number occupied was 741. The total number of in-patients was 13,552; total number of separate out-patients, 86,129; total number of separate casualty cases, 123,143; total number of home visits, 3,944; payments made by in-patients, £116; payments made by out-patients, £1,840; net income from investments, £11,375; total cost of maintenance, £82,801; total cost of management, £3,491. At the Charing Cross Hospital the average number of beds occupied was 169 out of an available total of 238. The total number of in-patients was 2,465; the total number of separate out-patients, 10,167; total number of separate casualty cases, 10,385; total number of home visits, 307. There were no payments by either in or out-patients. The net income from investments was £683; the total cost of maintenance, £18,863; and total cost of management, £2,117.

Prosecution under Dental Acts.

ON a charge of using the title "dentist," implying that he was registered under the Act, George Charles Smith, of 153, High Street, Lewisham, was last week at Greenwich fined 40s. and three guineas costs. The prosecution was at the instance of the British Dental Association.

The defendant said he had been on the dental register since 1878, but through some business regulations he had been struck off the roll. If the summons were adjourned for a month he would comply with the B.D.A.'s requirements.

Mr. Eves, for the prosecution, said that the defendant had been guilty of unprofessional conduct by advertising and employing unqualified persons.

The defendant said it was a case of professional animosity. For twenty-one years he was on the Register, and was the only registered dentist in Lewisham. He had to adopt business methods to compete with other dentists. He asked for an adjournment as he was forming "G. C. Smith, Limited."

Medical Exhibitions.

THE annual Medical Exhibition is being held in London during the whole of the present week, Saturday excepted, at the Royal Horticultural Hall, Westminster. It is arranged and controlled by the proprietors of the *British and Colonial Chemist and Druggist*. Last year's function proved a great success, and as the present is being run on similar lines and is strictly confined to members of the medical profession and all the available space has been taken up, there is every prospect of a successful issue. The exhibition is free to medical men, of whom upwards of 3,000 were present last year. Another venture is contemplated under the title of a "Travel Exhibition." This will open at the Royal Horticultural Hall, Westminster, May 24th to June 8th, 1907, and will graphically illustrate and demonstrate how the public throughout

the world travel, where they travel, the means by which they travel, the thousand-and-one *et ceteras* connected with travel. Manufacturers will be represented by every article required *en route*, whether on a journey of fifty or thousands of miles. The latter exhibition is being organised and arranged by the directors of *Health Resort*.

Delamere Sanatorium New Joint Scheme.

The Manchester Hospital for Consumption and Diseases of the Throat and Chest and the Crossley Sanatorium at Delamere are the subjects of a scheme which has been prepared for their administration, and is under the consideration of the Charity Commissioners under the provisions of the Charitable Trusts Acts, 1853 to 1894. Under the scheme the endowments of the two charities are to be consolidated and managed as one institution under the title of the Manchester Hospital for Consumption and Diseases of the Throat and Chest. The body of trustees for the institution is to consist of sixteen, who shall be entitled to hold office for life. The real estate belonging to the institution includes 8,208 square yards of land at Dunham Massey, with the hospital building on part thereof, 645 square yards of land in Hardman Street, Manchester, with the out-patients' department on it, and seventy-three acres with the sanatorium at Delamere. The personal estate amounts to over £16,000 in respect of the Hospital for Consumption, and over £63,000 in respect of the sanatorium, making together about £80,000,

Transmission by Post of Pathological Specimens.

The Postmaster-General has recently revised the regulations governing the transmission by post of deleterious liquids and substances sent for medical examination or analysis, and on and from the 1st proximo such specimens may be sent by Letter Post, without registration, by qualified medical practitioners and qualified Veterinary surgeons under the following conditions:—

(1) that they are addressed to a laboratory or institute, public or private, or to a medical practitioner or veterinary surgeon within the United Kingdom;

(2) that they are enclosed in a receptacle hermetically sealed, which receptacle must itself be placed in a strong wooden, leather, or metal case in such a way that it cannot shift about, and with a sufficient quantity of some absorbent material (such as sawdust or cotton-wool), so packed about the receptacle as absolutely to prevent any possible leakage from the package in the event of damage to the receptacle;

(3) that they are conspicuously marked "Fragile with Care," and bear the words "Pathological Specimen," and also the signature and address of the medical practitioner or veterinary surgeon who sends them.

The packets must on no account be sent by *Parcel Post*. Any packet of the kind found in the Parcel Post, or found in the Letter Post not packed and marked as directed, will be at once stopped and destroyed with all its wrappings and enclosures.

Any person who sends by post a deleterious liquid or substance for medical examination or analysis otherwise than as provided by these regulations is liable to prosecution.

It is recommended that if receptacles are supplied by a laboratory or institute to medical practitioners or veterinary surgeons, they should be submitted to the General Post Office, in order to ascertain whether they are regarded as complying with the regulations.

Preservatives in Milk.

The Local Government Board, Edinburgh, have issued a circular calling the attention of local authorities to the subject of the addition of preservatives to milk. The Departmental Committee of the Local Government Board for England stated that preservatives were objectionable on the ground of public health, and were also unnecessary for the purpose of the milk trade. The Board accordingly suggest that the local authorities should cause samples of milk to be taken with a view to ascertaining the presence of substances commonly in use as preservatives—*e.g.*, formalin and boric] preservatives. The Board are advised that, as regards formalin and boric preservatives, the presence in milk of formalin to an amount that is ascertained by examination within three days of collecting the sample to exceed 1 part in 40,000 (1 part of formic aldehyde in 100,000) raises a strong presumption that the article has been rendered injurious to health, and that the purchaser has been prejudiced. Similar presumption is raised where boric preservatives are present in milk to an amount exceeding 57 parts of boric acid per 100,000, or 40 grains of boric acid per gallon.

Anthrax in Cheshire.

The following circumstances attending the death of a farm labourer, due to anthrax, have been disclosed at an inquest in Liverpool. About two weeks ago an apparently healthy cow was killed on a farm in Norley, Mid-Cheshire, and after being dressed, was sent to the Manchester Meat Market Traces of anthrax being discovered, several other suspected carcasses and a large number of hides were destroyed. A few days later two farm hands became ill, and were found to be suffering from anthrax. The men were conveyed to the Royal Infirmary at Liverpool, where one rapidly became worse and died. The case of the other is regarded as hopeful.

London Medical Man Robbed.

Edwin John Bell, 22, described as a pianoforte-tuner, of East Finchley, was last week charged at Highgate Police Court, and was sentenced to six months hard labour, for stealing articles, valued at £14 6s. from two surgeries at Muswell Hill. Dr. Lawrenson stated prisoner called two or three times "collecting for lepers," and on the 30th ult. was shown into the surgery. He asked witness to lend him a surgical instrument catalogue, and he took one away with him. Next morning witness missed a case of surgical instruments, value six guineas. Dr. Donald Munro lost a microscope, value £8. Detective Goode arrested prisoner with the case in his pocket. At his lodging he found other surgical instruments. He had been collecting for charities, but had not paid the money over.

PASS LIST.

The Royal University of Ireland.

The following candidates have passed the Second Examination in Medicine:—

Upper Pass.—*Albert V. Craig, *Richard W. G. Hingston, *David Horgan, John C. Houston, *John C. Johnson, Edward G. Kennedy, *Ernest W. Kirwan, *Patrick J. Lydon, *John M. McCloy, *Peter J. Ryan, *William W. D. Thomson, Michael Twohig, *William O. Wilson. Those marked with an asterisk may present themselves for the further examination for honours.

Pass.—Joseph Anderson, William J. Ashby, William Boyd, Francis Bradley, Patrick J. Cullinane, Michael G. Devine, William Dickey, William Doolin, William C. Dunne, B.A., Francis C. Ferran, B.A., William A. Frost, John J. Gilmore, William E. Graham, William Hamilton, James A. Hanrahan, Patrick Hayes, J. Hill, Sarsfield C. Kerrigan, Joshua Keyms, B. A. Bertram C. Letts, Denis Lynch, James McCormick. Samuel K. McKee, William Magner, Thomas C. Magnier, George E. A. Mitchell, Thomas J. S. Moffett, Daniel F. Murnaghan, Harris Newman, Jerome O Flynn, James J. O'Kelly, B.A., James M. O'Reilly, William Paul, David A. Rice, Thomas Scanlan, William Speedy,

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Antistreptococcic Serum as a Prophylactic and Curative Agent.—Fromme (*Münchener Med. Woch.*, 1906, *Nr.* 1) says that laparotomies during which infection may be easily transmitted to the peritoneum, for example in cases of pyosalpinx and carcinoma, make it desirable to render the patient immune to such infection from the very beginning. He has lately made much use of the anti-streptococcic serum for this purpose. He injects 10 to 20 ccm. of Menzer's serum daily with the most favourable results. As regards the use of the serum as a curative agent, it is most important to reserve it for pure streptococcal infections. It must not be used for saprophytic infections. It is very important also that the serum be injected as early as possible. After the formation of a purulent exudate, or when the streptococci have accumulated to an unlimited extent, the serum is contra-indicated. In cases of well-marked pyæmia, advanced septicæmia and advanced peritonitis, the serum may be injurious. Through the destruction of the streptococci, produced by the serum, a large amount of toxic proteins are set free, which may poison the patient. On this account the serum is most useful when dealing with streptococcal endometritis, as the author proved in six cases, because the proteins are discharged from the uterus before they can injure the organism. For the same reason, in order that the serum may be successful in streptococcal peritonitis, incision and drainage are very necessary. G.

Appendicitis and the Puerperium. — A case is described by Duvernay (*Lyon. Med.*, January 1st, 1905) as follows: A woman with slightly contracted pelvis, who had delivered herself spontaneously, developed immediately after her labour a slight rise of temperature. Examination of the genital tract revealed nothing pathological. There was a history of occasional pain in the region of the right kidney, but nothing further. The pulse remained rapid, the lochia normal. The abdomen was neither distended, nor tender to touch. On the eleventh day, the temperature rose to 39·7°. A digital examination was then made of the uterus, and some decidual remains were removed. They showed no signs of decomposition. The uterus was douched and packed. Immediately after this vomiting began, temperature rose to 41·3°, patient became unconscious, and died on the next day. The autopsy revealed pus among the intestines, the genital system in normal puerperal condition, and behind the cæcum, reaching nearly to the kidney, an old abscess in which the appendix was floating. The inner wall of the abscess cavity was perforated. The pressure during parturition, and later the examination and emptying of the uterus, probably produced the perforation, and thus led to the death of the patient. G.

Pemphigus Neonatorum.—Koblanck (*Zeitsch. für Geb. und Gyn.*, Bd. LVII., Hft. 3) describes a case which occurred in a two-para, who had slight vaginal and vesical catarrh during her pregnancy, and in whom there was a remarkably deep position of the fœtal head during the tenth month. The labour, which lasted for sixteen hours, began with rupture of the membranes, with, at the same time, very feeble pains. No internal examination was made. Immediately after its birth, pemphigius blebs the size of hempseeds were discovered on the skin of the body and arms of the child. The palms of the hands and soles of the feet were free. The blebs disappeared in a few days when treated with 70 per cent. alcohol. The child thrived. The mother had a normal puerperium. That it was not syphilitic pemphigus was absolutely certain. The intra-genital origin in this and similar cases is due to the rubbing into the delicate fœtal skin of the staphylococcus aureus during the passage of the child through the vagina. G.

Painless Labour.—Wolff, Berlin (*Archiv. für Gyn.*, Bd. LXXVIII., Hft. 2), describes the progress of a painless labour case which, after lasting for two days, was finished by him with forceps. Neither through the history, nor through examination up to six months post-partum, could any disease of the nervous system be discovered. The woman had no pains whatever; in fact, she would not believe that she was in labour. During the stage of expulsion, bearing-down efforts were absent. The author then describes several examples of this labour from English literature. This partus insensibilis seems to be more frequent than is generally accepted. Even though it has nothing to do with cases of precipitate labour due to an abnormally small amount of resistance, it seems probable that a case of this description is often hidden among the latter. It cannot be denied that painlessness of the labour pains is an early symptom of myelitis or tabes. Still, it may be also possible that the cause must be sought for in a peculiar condition of the genital system, perhaps an especially great dilatability. The absence of bearing-down efforts which is also observed in spinal anæsthesia indicates to us wherein lies the significance of the physiological labour pains, at any rate during the expulsive period. The intimate connection between bearing-down efforts and painful contractions is clearly seen when the labour is painless. Nature requires this intense irritation in order that the bearing-down efforts may be set in motion at the right time, and with all the strength of the woman. G.

Conditions which Contra-indicate and which Render Suckling by the Mother Impossible.—As contra-indications, Bouquet (*Bull. Generale de Therapeutique*, 1906, January 15-30th) mentions all forms of heart disease even when compensated, and albumenuria, but only when the latter is a symptom of Bright's disease, and not of the kidney of pregnancy. Above all, tuberculosis is a contra-indication both for the sake of the mother and child. Again, suckling must be forbidden when the mother suffers from any infectious disease, for example, typhoid, measles, or erysipelas. It is also contra-indicated by the onset of mastitis or the presence of malignant breast tumours. Whether chronic alcoholics should nurse their infants is a very important question. Such nursing can produce disturbances of the intestinal and nervous systems of the child. These disturbances are still more frequent in cases of chronic intoxication from lead, mercury, and arsenic. The author observed a mother who suffered from lead poisoning, and who had nursed her five children herself. They all died at an early age from convulsions. Alterations in the quality of the milk through which it becomes too poor to properly nourish a a child are also found. We cannot at present explain the cause of this with certainty. Suckling can also be impossible on anatomical, physiological, and social grounds. The former are rare; among them are included complete deficiency of the nipples, malformation of the mammæ, and more or less complete failure of secretion. An absolute failure of secretion does not occur. The author describes in conclusion the social grounds which prevent nursing by the mother, their results, and the means by which this evil may be removed.

G.

The Causation of Eclampsia is discussed by Dr. Liepmann (*Münchener Med. Wochensch.*, 1905, No. 51). In his first report he said the toxins are to be sought for in the placenta. In the meantime, further experiments have been made. The results of the intra-peritoneal injection of a solution of the powder prepared from the placenta of an eclamptic were always the same. The placental poison showed the following characteristics:—(1) It is closely incorporated with the albumen molecule; (2) it is very poisonous to rabbits; (3) it is extremely mobile; (4) it may be precipitated by the action of albumen precipitating substances; but (5) it is not yet possible to extract it. The more the poison has advanced into the organism the more convulsions appear, and the less amount of the poison is to be found in the placenta. On the contrary, the fewer the convulsions have been, the more toxic is the placenta. The placenta seems to be the place of formation and of exit of the poison. The latter shows a great affinity for the brain matter which it destroys, but is neutralised by it. Besides this, the poison is very injurious to the kidney parenchyma and to the liver. The injury to the kidney is always secondary to the poisoning. In cases where there is already albumenuria, the amount of the latter may be much increased. Immediate delivery is the best treatment. In connection with it, saline infusion and bleeding are useful. For coma and shallow respirations artificial respiration must be employed. Warm packing has an injurious action. According to Bumm, the profuse sweating concentrates the poison.

Treatment of Eclampsia.—With regard to Liepmann's work and his statistics, Esch (*Münchener Med. Wochensch.*, 1906, No. 15) seeks to show that there is danger of exaggerating the results of immediate delivery. In the Universitäts-Frauenklinik, Berlin, among 36 cases from May 1st, 1905, to January 1st, 1906, immediate delivery gave a mortality of 22.2 per cent., so it may be taken as proved that immediate delivery is not a specific curative agent. One must differentiate between severe and mild cases of eclampsia. When there is little or no coma, free respiration, and a good pulse, the expectant treatment is best. The severity and intensity of the attack is to be judged from its duration, and from its effect on the consciousness, respiration and pulse of the patient. The degree of the attack never changes suddenly. When dealing with multiparæ and primaparæ with dilatable soft parts and a dilating cervix, the membranes may be ruptured. Braxton Hicks' version is generally contra-indicated, because three-fourths of the eclamptics are primaparæ. When the internalos is not at all dilated, the practitioner must make up his mind whether he is in a position to perform rapid delivery, as this may become necessary at any moment. When he is not, he must send the patient to a hospital or call in a specialist. G.

The Causes of Death from Uterine Fibromyomata were found by Pellanda (Lyon, 1905) in 171 cases which ended fatally to be the following:—(1) Cachexia, 9 times (5.2 per cent.), pressure on the abdominal contents, exhaustion from blood loss, constipation, mild infection, phlebitis, heart and kidney changes. (2) Hæmorrhages, 11 times (6.4 per cent.). (3) The most common cause—infection, 85 times (49.5) per cent.). This occurred most frequently in combination with pregnancy, parturition, and premature labour. It is subdivided as follows:—(a) Gangrene, 47 times. Pedunctulated submucous tumours had caused death 9 times, because the drainage from the uterine cavity was not sufficient, and there was absorption; 16 times necrobiosis followed by gangrene and suppuration, which led to septicæmia. Peritonitis arose in 22 cases from rupture of the gangrenous mass into the peritoneum. (b) Rupture of a pyosalpinx, which occurred in 19 cases. (c) Peritonitis, which in some cases was complicated with pyæmia, was caused in 19 cases by degeneration of the tumours themselves or the adnexæ. (4) Compression of the abdominal and pelvic contents in 44 cases (25.8 per cent.), occlusion of the intestine occurring 20 times; pressure on the metra causing albumenuria, pyelonephritis, uræmia, 13 times. Pressure on the uterus vagina or the bladder, 11 times. (5) Thrombosis of the pelvic veins and pulmonary embolism and cardiac degeneration caused death 19 times (11.1 per cent.). (6) Twisting of the pedicle of a subserous fibromyoma. (7) Cases of pregnancy complicated with fibroids and malignant degeneration of the tumours are not included. Regarding the connection between fibromyoma and carcinoma, the greater frequency of carcinoma of the body of the uterus must be specially mentioned. The average age of death in the 171 cases was 47 years and 9 months. In the cases due to infection, death was earlier—42 years and 8 months. In cachexia, later—57 years and 5 months. Most deaths occurred between 36 and 42 and between 46 and 50, a very small number before 30 and after 60. In conclusion, the author says that, since death from fibromyomata is the exception, not the rule, operation is only needed where complications supervene, where the tumours increase in size after the menopause, or where their size makes it impossible for the patient to perform her daily duties. G.

Malignant Uterine Myomata.—Concerning these, Villard (Lyon, 1905) says, among other remarks, that myomata may undergo sarcomatous degeneration, especially at the time of and after the menopause. Rapid growth and the reappearance of uterine hæmorrhage after the menopause are the best clinical signs. Ascites and cachexia are not of so much value. Malignant myomata may be confused with cancer of the body, with pregnancy in a fibroid uterus, solid or cystic tumours of the ovary, and peritoneal cancer. The frequency of malignant degeneration is difficult to estimate. G.

Abdominal Myomectomy.—M. Bonier (Lyon, 1904) says the ideal procedure is to combine the removal of the tumours with the preservation of the uterus, especially when we are dealing with benign tumours. This is nearly always possible, since the tumours are generally circumscribed and without adhesions. In this way menstruation and fertility are preserved, and such unpleasant results as the premature menopause and atrophy of the vagina are prevented. A very profuse development of tumours, and the diffuse form, indicate hysterectomy. The younger the woman the greater must be our efforts to make the operation as conservative as possible. Cases of pregnancy after myomectomy are fairly frequent. Deeply-lying fibromyomata must always be removed, since they may interfere with pregnancy or parturition. Myomectomy is more dangerous and more difficult than hysterectomy, but the later results prove its superiority. Recurrence of the fibroids is very rare. G.

Gonorrhœa and the Puerperium.—Meyer (*Monatssch. f. Geb. und Gyn.*, June, 1906) says puerperal gonorrhœa is a much more dangerous complication than it is usually considered to be. It can produce high fever (40 deg.), and severe general infection, with rigors, giving the clinical picture of a septic condition. How much this general infection is due to toxic poisoning or the invasion of the circulation by gonococci, cannot yet be determined. Remissions and intermissions of the fever, with febrile periods lasting for some days, is not an absolute proof of puerperal gonorrhœa. The generally accepted idea that late fever is characteristic of gonorrhœa must not always be accepted. Whether the gonorrhœal endometrium is unfavourable to the proper formation of the placenta, or whether the growing ovum may be influenced by poisoning from toxins due to the gonococci, cannot yet be decided. G.

Mr. J. S. McArdle will deliver an address introductory to the Medical Session in the Theatre of St. Vincent's] Hospital, Dublin, on the 9th inst., at 4.30 p.m.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

J. L. WATSON.—Although formaldehyde as a preservative undoubtedly exhibits the growth of bacteria, it does not kill tubercle bacilli in milk even in a 1-5,000 solution. There is some evidence that 1-10,000 solution can cause injury to the mucous membrane of the child's intestines.

METHYLENE.—Gonococci may be stained by methylene blue. It is said that even 1-10,000 for 10 seconds will demonstrate them.

READER.—You can still get W. E. Henley's little book "In Hospital." The poems form a record of his experience in the Edinburgh Infirmary in the early seventies. His work, either medical or poetical, was never impaired by his exhausting illness, tuberculous arthritis.

DR. S. (Bath).—You will get comparatively little for your books. Some could be disposed of privately, but a dealer will only give you so much a hundred. Books which have cost 35s. often go for 5s.

MR. J. H. H. (Manchester).—We cannot undertake the experimental enquiry to remove your objections as you suggest. This work has already been done by others, but it has not convinced you, nor would any further facts we could adduce remove your prejudice.

INSTRUCTOR (Edinburgh).—The new work on Anatomy, by Prof. Buchanan, has, we understand, already proved its need by a strong demand. The book is fully referred to in our last issue.

R. H. M.—Nitric oxide combines with hæmoglobin and forms NO-hæmoglobin.

MOLAR.—The draft of the Ordinance for regulating the qualification and providing for the Registration of Dentists in Hong Kong was forwarded to, and considered by, the General Medical Council on Feb. 26th, 1906.

C. T. M.—Yes, gelatine does give a violet blue reaction.

A. H.—The motion to appoint a Dublin surgeon instead of an English or Scotch one at the Apothecaries' Hall, Dublin, was withdrawn by the proposer.

ACTINOMYCOSIS.—You are right in saying that the ray fungus was first found in pus from the human subject.

CANADA.—The virulence of anthrax bacilli are destroyed by putrefaction, but the spores are not affected.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 3rd.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. Eden, Dr. R. D. Maxwell, and Dr. H. R. Andrews. Short Communication:—Dr. Eden and Mr. F. L. Provis: A Case of Intra-ligamentous, Fibro-cystic Tumour of the Uterus, weighing about 30 pounds, Successfully Removed by Enucleation and Sub-total Hysterectomy. Paper:—Mr. E. E. Young: Primary Tuberculosis of the Cervix.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. T. P. Legg: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. G. H. Savage: Lucid Intervals in Cases of Insanity.

THURSDAY, OCTOBER 4th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Diseases of the Eye.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. G. F. Still: Head-nodding and other Curious Movements in Children.

FRIDAY, OCTOBER 5th.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 p.m.: Presidential Address:—Dr. L. Mark: Art and Medicine.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Medical and Surgical Clinics. 2.15 p.m. Diseases of the Throat, Nose, and Ear. 2.30 p.m.: X-Rays. Operations. Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. D. Grant. Clinique. (Ear.)

SATURDAY, OCTOBER 6th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

MONDAY, OCTOBER 8th.

THE MEDICAL SOCIETY OF LONDON.—8.30 p.m: First Ordinary Meeting of the Session 1906-7. Mr. Charles A. Ballance, M.V.O., M.S. (incoming President): Opening Address. Mr. T. H. Kellock: Paper:—"Actinomycosis of the Vermiform Appendix."

Vacancies.

Birmingham Queen's Hospital.—Pathologist. Salary £100 per annum. Applications to the Secretary.

Cheshire County Asylum, Macclesfield.—Junior Assistant Medical Officer. Salary £140 per annum, with apartments, board (no alcohol), and washing. Applications to the Medical Superintendent.

City of Birmingham Asylum, Rubery Hill, near Birmingham.—Male Junior Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, &c. Applications to the Medical Superintendent.

City of Liverpool.—Assistant Medical Officer of Health. Salary £250 per annum. Applications to Edward R. Pickmere, Town Clerk, Town Clerk's Office, Liverpool.

City of Liverpool.—Infectious Diseases Hospital.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, washing, and lodging at the Hospital. Applications to Edward R. Pickmere, Town Clerk, Town Clerk's Office, Liverpool.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Manchester Royal Infirmary and Dispensary. Honorary Assistant Physician. Applications to the Chairman of the Elective Committee, on or before October 31st. (See advt.)

Royal Victoria Eye and Ear Hospital.—House Surgeon. Immediate application to the Registrar, Adelaide Road, Dublin. (See advt.)

Staffordshire County Asylum, Cheddleton, Leek.—Assistant Medical Officer. Salary £150 per annum, with furnished quarters, board, and washing. Applications to the Medical Superintendent.

The Finsbury Dispensary, Brewer Street, Goswell Road, E.C.—Resident Medical Officer. Salary £140 per annum, with furnished residence in the institution, with attendance, coals, and gas. Applications to W. H. Pratt, Secretary.

The Royal Portsmouth Hospital, Portsmouth.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to B. Wagstaff, Secretary.

Wolverhampton and Staffordshire General Hospital.—House Physician. Salary £100 per annum, with board, lodging, and laundry. Applications to J. Stephen Neil, House Governor and Secretary, Wolverhampton.

Appointments.

CASHMAN, JAMES P., M.B., B.S.R.U.I., Resident Medical Superintendent of the Cork District Asylum.

DAWNAY, A. H. PAYAN, M.R.C.S., L.R.C.P.Lond., Honorary Ophthalmic Surgeon to the Hounslow Hospital.

JEPHCOTT, CHARLES, M.B., B.S.Cantab., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Chester Union by the Chester Board of Guardians.

MOSSOP, E. E., M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., House Physician to the Hospital for Sick Children, Great Ormond Street, W.C.

RENDALL, PERCY, M.D., M.R.C.S., Divisional Surgeon to the V Division of the Metropolitan Police at Epsom.

TIVY, CECIL B. F., M.B., B.Ch. R.U.I., House Surgeon to the Cork Eye, Ear, and Throat Hospital.

Births.

BALDERSTON.—On Sept. 30th, at 17 Westbourne Road, Forest Hill London, the wife of Robert Balderston, M.B., of a daughter.

GOUGH.—On Sept. 25th, at Compton Martin, near Bristol, Somerset, the wife of Bernard Bradly Gough, M.R.C.S., L.R.C.P.Lond., of a daughter.

PRITCHARD.—On Sept. 27th, at Roden House, Church Road, St. Leonards-on-Sea, the wife of W. Clowes Pritchard, M.R.C.S., L.R.C.P., of a son.

Marriages.

BURGESS—THOMPSON.—On Sept. 28th, at St. Thomas's Cathedral, Bombay, Captain J. Hay Burgess, M.B.Lond., F.R.C.S.Eng., I.M.S., eldest son of the Rev. William Burgess, of Rome, Italy, to Mary Ethel, daughter of the late Thomas Thompson, of Hull and Beverley, E. Yorks, and Mrs. Thompson, Newhaven, Trinity Road, Bridlington.

DE CASTRO—LYNN.—On Sept. 26th, at St. Anselm's Church, Davies Street, Berkeley Square, George de Castro, M.R.C.S.Eng., L.R.C.P. Lond., of 79 Davies Street, London, to Lucy, youngest daughter of the late Palmer Lynn, of Brighton.

HALE—NORTON.—On Sept. 25th, at Rickinghall, Suffolk, Lancelot Hugh Downman Hale, M.R.C.S., L.R.C.P., D.P.H., of Chillington, S. Devon, son of the late Rev. E. Hale, of Eton College, to Harriet, eldest daughter of the late C. T. Norton, Esq., of Hill House, Rickinghall.

WYLIE—HALSEY.—On Sept. 28th, at St. Phillip's Church, Georgetown, British Guiana, Angus Wylie, M.A., M.B., second son of Dr. G. Hamilton Wylie, of Hampstead, to Kate, youngest daughter of D. N. Halsey, Brighton.

Deaths.

BETENSON.—On Sept. 28th, at Sussex Lodge, Newhaven, Mildred Septima, beloved wife of W. B. Betenson, M.R.C.S., L.R.C.P., aged 41.

MARRIOTT.—On Sept. 27th, Sarah Ann, the beloved wife of Charles W. Marriott, M.D., at Aubrey House, Reading, late of Leamington, aged 67.

SPARKE.—On Sept. 26th, at "Tweedale," Brasted, Kent, Ann, wife of George Whitefield Sparke, M.R.C.S., aged 72.

STOKES.—On Sept. 27th, at Howth, Whitley Bland Stokes, M.D., M.R.C.P., F.R.C.S., of 37 Onslow Square, London, youngest son of the late Henry Stokes, Esq., of Askive, Sneem, co. Kerry, aged 42.

STEWART.—On Sept. 28th, at Angelton, Bridgend, Robert S. Stewart, M.D., D.P.H., Superintendent of the Glamorganshire County Asylum.

THOMASON.—On Sept. 24th, at Drybridge House, Hereford, Richard Thomason, M.R.C.S., L.S.A., J.P., aged 77 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, OCTOBER 10, 1906. No. 15.

NOTES AND COMMENTS.

London Medical Exhibition.

Medical men who missed seeing the London Medical Exhibition last week missed a great event. The Exhibition was twice as large as the first one of its series held last year, and everything that enterprise and forethought could do to make things comfortable and convenient for visitors was done. We publish a special article in another column giving some idea of what was to be seen on the stalls, but the exhibition really was a liberal education in modern medical and surgical methods, and no description could give a sufficiently concrete idea of what was to be seen and learned. The exhibition was got up by the "British and Colonial Druggist," and those who had the opportunity of enjoying their hospitality will be only too glad to accept it again, when it is offered.

"Burkard's Vegetable Compound."

The extraordinary slackness, not only of the public authorities, but of the public themselves, with regard to the danger of patent medicines, was never more strikingly illustrated than by what occurred at an inquest held by Mr. Wynne Baxter at Stepney on October 1st. The subject was a woman, aged 50, who had suffered from indigestion and rheumatism for some time, and who had taken some tablets from a sample packet which had been thrust under the door of the house she worked at. This packet had on the outside an advertisement stating that Burkard's Vegetable Compound would cure pains in the back, tired feeling in the morning, and the usual list of symptoms that one knows so well. There was also the word "poison" on the outside. The advertisement proceeded: "Are you stupid? Are you nervous? Are you losing weight? If so, Burkard's Vegetable Compound will cure you." If one tablet was not enough, two were recommended to be taken. Well, the woman took two tablets, had excessive diarrhœa, and died. The doctor who was called in said that death was due to the result of the tablets, and the Coroner expressed a similar view in more flippant language. "The probability is," said he, "that the tablets finished her off." The jury returned a verdict of "Death from misadventure."

And Public Apathy.

To us as private citizens, apart from our professional knowledge or inclinations, there is something particularly shocking in this tragedy—not only in the fact of death itself, but in the freedom with which "poison" can be put into the homes of the poor, with flamboyant statements as to what it can do for them in their ailments. According to the report we have before us, the case was taken as a kind of farce, the jurymen bandying witticisms and cracking jokes, so that one cannot be altogether surprised that they arrived at the lame and impotent conclusion of "Death by misadventure." Here was a case directly due to the taking of a quack drug, according to both coroner and medical witness, and yet no steps were taken, or seem likely to be taken, to bring home the fact to those who supplied the medicine, in the way that such fact in a properly-governed community should be brought home, and for all we know "Burkard's Vegetable Cure" is still being pushed under the doors of houses where the poor work. There is a very severe punishment for putting strychnine in meat to poison a dog, but the death of human beings from admitted "poison" is regarded as a subject for a joke. Would that Dickens were alive!

"Silly Ass" Novel.

There is a Mr. Domoney, chairman of the Streets Committee of the City of London, who presents such an extreme type of the reactionary that one cannot but rather admire him, as one admires the old-time port-and-Bible country squire who would not hear of letting the railway approach his estate. This Mr. Domoney was much moved to wrath at a recent meeting of the Common Council, at which it was suggested that a communication should be addressed to the Local Government Board relative to the importation and inspection of meat. "What was the matter," he asked, "with the public health?" "What," he proceeded, "was the matter with the ordinary healthy man or healthy woman? All that medical science was doing was to keep a lot of wastrels alive. He was perfectly well now, but did not know whether the meat he ate came from an abattoir or a slaughter-house, and though he ate oysters all through the scare, he never suffered. It was all through some silly ass novel. He hoped the Court would not be led away by doctors or experts of any kind." Mr. Domoney is one of those who are fighting a strong rear-guard action against overwhelming odds. People are beginning to realise that health and happiness for the million are not to be secured by eating and drinking everything retailers like to deposit at the door.

Midwives' Congress.

THE opponents of the registration of midwives have always maintained that their official recognition is certain to create sooner or later an inferior order of medical practitioner. It seems hardly within the probabilities of

human nature that midwives will stop short at midwifery. No such tendency was shown at the recent Congress of Midwives held at Dusseldorf. Associations to the number of 228 and members to the number of 11,501 were represented thereat. The telegraphic reports remark tersely that the speakers did not confine their remarks to obstetrics. Among other subjects they discussed measures for the reduction of infantile mortality, and had much to say on the subject of antiseptics. This extension of professional interest suggests an encroachment upon the medical treatment of infants as part of the midwife's work. The general practitioner has himself to thank for the appearance of the certificated midwife on the scene as one of his many unqualified competitors. Even now by vigorous action he could reduce the midwives to their proper sphere, and at the same time rescue the community from the dangers of further amateur doctoring.

LEADING ARTICLES.

THE TREASURY AND QUACK PROSECUTIONS.

MEDICAL men are perhaps rather too wont to imagine that the only road to the suppression of the bogus medical competition that flourishes on all hands lies through fresh legislation. While it may be true that the evil can never be entirely scotched without a general strengthening of the Medical Acts and of the general powers of the Medical Corporations and the General Medical Council, there is nevertheless a vast amount of machinery in existing laws available for the purpose. An obvious fraud upon the public is punishable as a criminal offence. If a man publishes wilfully false statements in order to procure money he is liable to prosecution for false pretences. If more than one person is involved the offence is treated as a conspiracy to defraud. Now, the published advertisements of many quack medical practitioners, as well as of many quack medicines, claim to cure incurable conditions, and to perform other therapeutic feats that can readily be shown to be impossible. This says nothing of the fact that these pretenders are assuming the ability to perform acts which appertain to competent medical practitioners, whose education and qualifications Parliament has directed and controlled in the most stringent manner possible. The Government of the United Kingdom have neither conferred upon the medical profession the ability to defend itself against the gross competition of unqualified practice, nor, on the other hand, have they taken steps to protect the public against the frauds in question. To a certain extent the general accusation of laxity in protection of the public against gross and notorious frauds may be brought against the Treasury. The Public Prosecutor is a picturesque figure, whose activities are intermittent, unequal, and apparently irresponsible. He prosecutes or does not prosecute offenders against the common welfare in a wayward fashion that robs his office of the confidence it would enjoy if its duties were carried out systematically and on certain clearly-defined principles. So far as the medical profession is concerned, the Public Prosecutor might as well be non-existent; although at the present moment there is far more absolute fraud carried on under medical and semi-medical guises than would occupy the whole time and energies of a second Public Prosecutor. Almost any large journal or magazine taken at random would furnish material for half a dozen prosecutions. Take, for instance, a leather strap, "stuffed with fragrant Eastern herbs," which is warranted to remove wrinkles. Yet the advertisement of such a strap has appeared for years past in the columns of a weekly journal whose special boast is the exposure of frauds upon the public. In spite of their general deplorable laxity, however, of late the Treasury has shown commendable signs of an awakening sense of responsibility in the matter of quack prosecutions. Several notorious electrical and other quacks have been convicted in various parts of the kingdom, and are at the present moment paying the penalty of their misdeeds. We are glad to note that lately, at Brighton, an alleged offence of the kind was brought before the police-court. Two men named Hawkins were charged "that they did unlawfully conspire, combine, confederate, and agree together, by divers false pretences and subtle and fraudulent means and devices, to obtain money and valuable securities from such of His Majesty's liege subjects as should thereafter purchase from them certain powders, and to cheat and defraud them of such monies and valuable securities on January 1st, 1906, and divers subsequent days."

The indictment, reduced to a sentence, charged the men with obtaining money on false pretences. The evidence was to the effect that a world-wide trade was carried on in England, India, Africa, Australia, America, and "various other places." The accused were stated to have traded at several addresses and to have used a number of aliases, among them "Dr. Hawkins, M.D., U.S.A.," "Rev. John Wilson," and "Rev. Thomas Stone." They claimed to cure different diseases by means of powders, and applicants were advised by letter—in some cases, as given in evidence, on the strength of a form for recording the correspondent's symptoms. On analysis certain of the powders sold by accused were said to be composed mainly of bromide of potassium, bicarbonate of soda, and a little quinine. It is obvious that powders of that composition could not have a great monetary value. One of Hamiltons' circulars, however, was said by counsel for the prosecution to have stated that a chemist would charge 28s. for making up these powders, but "our charge is 18s. 9d., which is really cost price." At the time of writing the result of the prosecution has not been announced, and we are therefore unable to do more than sketch briefly the ground of action. Whatever the result may be in this particular case, the fact that the Treasury is at length undertaking such prosecutions should be a matter of congratulation not only to the medical profession, but to all concerned in protecting the public from a serious source of physical and moral degeneracy.

MRS. ALICE ESSERY, wife of a chemist, was last week committed for trial at Plymouth on eight charges of performing illegal operations since last Christmas. Four young women, of whom one was married, gave evidence that they had been to the defendant's house and were there operated upon. Bail was refused.

NOTES ON CURRENT TOPICS.

The Release of Mr. Edalji.

It is officially announced that Mr. George Edalji, who was sentenced three years ago to seven years' penal servitude for cattle maiming, will be released in a few days' time. Readers of the Medical Press and Circular will remember that we presented a memorial to the then Home Secretary, Mr. Akers Douglas, pointing out that if a solicitor did actually commit so brutal and purposeless a crime, it must have necessarily been the outcome of insanity, in which case he should have been sent to Broadmoor instead of Parkhurst. That petition was signed by some of the most eminent lunacy experts in the United Kingdom. An independent petition was also presented appealing for his immediate release on the score of innocence. The present Home Secretary, Mr. Herbert Gladstone, in releasing Mr. Edalji, appears to have endorsed the theory of innocence, which we are glad to approve as the only logical alternative to insanity. The whole occurrence, however, offers a scathing exposure of the weakness of our criminal law, which offers no chance of judicial appeal to a prisoner. In this particular case the evidence from the first was obviously of an untrustworthy nature, and a man has since been convicted of similar offences in the same locality. Mr. Edalji, in any event, will have to pay a terrible price for the defects of our criminal law. He has spent three of the best years of his life among the horrors of penal servitude. He returns to social life a marked man, and deprived of his qualification as a solicitor. He has been released, but his innocence has not been proclaimed. If he had been deemed guilty Mr. Herbert Gladstone would hardly have reduced his sentence by more than half. We congratulate those who signed our petition upon this result. At the same time it is much to be regretted that official reticence permits no public explanation of the weight attached to our arguments. As Mr. Edalji is restored to freedom, and has not gone to Broadmoor, the only possible inference appears to be that he has received the benefit of a tardy recognition of his innocence.

Dr. McAlister on the General Medical Council

Among the many interesting and valuable addresses that have marked the opening of the present winter session, perhaps no single one is more important than that delivered at Manchester University by the President of the General Medical Council. Of that address we publish a full abstract elsewhere in our columns. As might be expected, the discourse was able, eloquent, and learned, but upon the ardent reformer its doctrine must fall with the shock and unpleasantness of a sudden cold douche. When Professor McAlister recently assumed the presidency of the Council it was hoped in many medical quarters that a new era of progress and reform had begun. Judging from his Manchester address, however, he appears to have already fallen deep into the rut of official pessimism. His defence of the Council is based on its constitution, by which its work is defined as the maintenance and regulation of a *Register* of qualified men and the control of medical education. It is the defective constitution that is the main object of unfavourable criticism in the profession. Professor McAlister tells us in one breath that the Councils work is limited, and in the next he hints at its influence with the Privy Council and boasts of how it has acted *ultra vires* in instituting a student *Register*, and in other ways. He fails to inform us, however, why the Council has refused to increase the number of direct representatives, a step whereby that body would be rendered the mouthpiece of medical practitioners instead of medical corporations. Every one knows that the Council has no direct powers to prosecute quacks, but its very being, as shown plainly enough by the President himself, sprang from the desire of government to protect the public. Surely, if it be necessary to "hall-mark" duly qualified medical practitioners in the interests of the community it is no less imperative to punish unqualified pretenders, who are deadly parasites on Society. The latter function, we maintain, is an inevitable corollary of the former. It is not a little discouraging to find the learned President of the Council making so emphatic a declaration of the impotence and disabilities of that body in forwarding the interests of the general practitioner, who, after all, forms the backbone of the profession, and is likely to survive the wreck of selfish corporations and of pessimistic officialism.

Brighton Bumbledom.

If the question were put to a body of medical men, acquainted with the demands of the scientific treatment of disease, whether a town with 150,000 inhabitants required a resident medical officer at its workhouse with 1,400 inmates, there could be no hesitation about the answer. A visiting medical officer, be he never so efficient, is obviously unable to do all that should be done for the proper diagnosis and treatment of the diseases of so large a number of people, together with the proper training and supervision of the nurses, especially when he is engaged in private practice. Not that a visiting medical officer is unnecessary, but it is clear that a staff of two medical men, one resident and one visiting, is the minimum that such an institution needs. A long and heated debate on the proposition that a resident medical officer should be appointed at the Brighton Workhouse took place at the Guardians' meeting last week, and in the result bumbledom won, and the inmates and the nursing are to go on as before. Although some bitter things were said by certain extreme individuals, the Board as a whole were thoroughly satisfied with their present medical officer, who is both diligent and capable, and the question practically resolved itself into whether he should have the assistance he obviously needs. Moreover, it seems that the infirmary cannot become a complete nursing school without a resident officer, and that, therefore, the probationers are placed at a disadvantage. This argument was quite without effect on some of the guardians, who seemed to regard the training of nurses as a kind of new-fashioned luxury strongly to be opposed by enlightened reaction-

aries. The question was not one merely of expense, for the salary of a medical officer could have been saved out of the lower wages acceptable by probationers who wish for full training, but new and modern accommodation would have been a necessity. In a town of the wealth of Brighton this economising in the comfort of the sick and the efficiency of their institutions is not particularly creditable; indeed, it would be easy within the bounds of courtesy to use a stronger, and perhaps truer, adjective.

Educational Grants in Ireland.

From two prominent institutions in Ireland come complaints of the parsimony of the Government in educational matters. Professor Hamilton (President of the Queen's College, Belfast), in his recent report, has again to express regret at the inadequacy of the Treasury grant to the College Equipment Fund. The President, however, adds to his report a list of the various buildings which are in process of construction, and it certainly does not appear from them that the equipment fund has in any way suffered from Government parsimony. This is, however, entirely due to private munificence. The governors of the Royal Veterinary College of Ireland have, we think, deeper grounds for complaint, inasmuch as although the State has provided them with certain buildings and an endowment, it has given them no means of completing the buildings or equipping them properly. At the annual meeting of the College, which took place last week, the President of the Board of Governors—Sir Christopher Nixon—called attention to the present most unsatisfactory state of affairs. There is no question that additional funds must be provided if the work with which the College is charged is to be properly carried out, but we fear that at present the outlook towards Government aid is not hopeful. The fact of the matter is that enormous sums of money are required for educational purposes in Ireland, but too many of those who undoubtedly have educational matters deeply at heart are asking not alone for what is necessary, but also for what must be regarded as luxuries. Proper university education is a necessity—a university in which each man will find his own religion and politics rampant is a luxury. Improved scientific education is a crying need—the learning of Irish is a valuable literary pastime. At present, however, luxuries are so magnified into necessities that any Government must be excused which fails to distinguish between them, and which, being unable to help both, ends by neglecting the more essential.

A Noted Quack.

During the past few years there has been greater attention given than heretofore to the study of the history of medicine, and, naturally, ancillary to it is the study of quackery. The series of sketches of famous quacks at present appearing in the pages of the "Practitioner" is therefore opportune. The current number recalls the career of that prince of mountebanks, John St. John Long. Like many adventurers of his time, he was by birth an Irishman, and being of humble origin, he was dependent on his wits for his living. During early manhood he worked as a painter and drawing-master, first in Louisville, and afterwards in London, where he was employed in a menial capacity in the studio of Sir Thomas Lawrence. His first relation to the art of surgery seems to have been when he was engaged to colour drawings for the teacher of anatomy at one of the London schools. This suggested to him to start in practice as a healer, and having pretended to discover a liniment of great potency, he was not long in attracting enormous numbers of patients. He must have been a man not only of insatiable ambition, but of very marked gifts, since, depending entirely on them, he soon became one of the most petted figures in London society. Among his other inventions was a gigantic inhaler, round which he grouped his patients, each inhaling through a separate tube. This apparatus, indeed, seems to have been strikingly like one introduced during our own time for the treatment of consumption. From the moment of his starting practice in 1827 up to 1831, Long is said to have received over ten thousand a year in fees. In that year a patient died as the result of his too patent liniment, and he was tried for manslaughter and found guilty. The judge fined him £250! Again, within a few months, he was tried for manslaughter, but acquitted. In 1834 he died of consumption, at the age of thirty-six, having retained his extensive practice and his influential friends to the last.

Employment of Women.

Mr. Chamberlain, in the early days of the Tariff Reform movement, used to argue that British trade was so much cut into by that of foreigners that if this country wished to retain any commerce she would, unless his policy were adopted, be forced to cheapen production by abandoning the Factory Acts. Without staying to argue whether that contention is sound or not, it is pertinent to observe that the Factory Acts, which naturally impose a certain burden on the cost of production, are no handicap to trade if all countries have similar labour laws. The duty, then, lies on statesmen so far to come to terms with the representatives of foreign countries as that the conditions of labour shall be the same in all countries. If that be secured each country will be able fairly to exploit its own products to the greatest advantage. This international regulation of factories is, fortunately, what is already happening. An important conference, attended by representatives from the civilised Powers has just been held at Berne, and at it international regulations for the employment of women were laid down. It was agreed that, except under extraordinary conditions, no woman should be allowed to be employed between the hours of 10 p.m. and 5 a.m. in workshops or factories employing more than ten workers. Another agreement was come to among some of the States—namely, Denmark, France, Germany, Holland, Switzerland, Italy, and Luxembourg—that white phosphorus should not be imported, used, or sold, for the manufacture of matches. It is regrettable that Great Britain

did not see its way to join in this benevolent regulation.

A Flutter in the Dove-Cote.

There is an institution, called the Nurse's Hostel, situated in Francis Street, London, W.C., which is theoretically admirable, but whose practical organisation seems far from effective. This hostel was built to provide independent nurses with a refuge whilst waiting for patients, a kind of glorified boarding-house, quite different from the ordinary nursing home. Now it is clear that not only is it more profitable for a competent nurse to work on her own account, but also that the public is likely to be better served when a nurse's engagements depend on her private reputation than when she is merely exploited by the proprietor of a nursing home as a means for earning commission. The chief *raison d'être* for the nursing home is that a medical practitioner knows that he can rely upon getting a nurse in an emergency, whereas if he sends to a nurse in practice for herself he may find her already engaged. But the nursing home which pays its nurses a salary and lives on their earnings clearly does not give the nurse that proportionate share of the profits of her labour to which she is justly entitled. The hotel or common lodging-house system in which nurses live together and pay for what they receive is a far more satisfactory and equitable arrangement. But it is necessary that it should be run on businesslike principles, and the Nurses' Hostel in Francis Street seems to have started inauspiciously. The superintendent gave little satisfaction to the nurses, and the vital department of the telephone seems from accounts to have been seriously at fault. The essence of a nurse's life is that she should be available at a moment's notice, and that correct information as to her whereabouts should be forthcoming when wanted. The nurses naturally rebelled, and we see it stated the managing directoress thought there was a "lack of discipline" in the institution. From what we can gather the nurses would have been exceedingly foolish to have disciplined themselves to the point of putting up with such management, and we trust that an institution with so many admirable points will be sufficiently reorganised to afford all the facilities that its patrons look for.

Medical Morality.

The correspondence on the "Scarcity of Doctors," on which we commented last week, has attracted a good deal of notice, and various causes have been given for the alleged scarcity. Incidentally another and even more important subject has been opened up in connection with this scarcity question—namely, public opinion with regard to medical morality. "M.R.C.S.," writing in the *Standard* of October 2nd, says that a few of the shady things he has been asked to do in practice have been to:

1. Put a false age on a death certificate, so that the friends might get insurance money.
2. Say that a man was sober at the time of an accident, when he had good reason to think he was intoxicated.
3. Sign for total disablement when a man was doing some of his work.
4. Postpone vaccination indefinitely on account of illness when the child was well.
5. Give a certificate of good health for the insurance of a man with chronic disease, liable to terminate fatally at any time.

Is the experience of "M.R.C.S." exceptional? We fear not. There are temptations in every walk of life, of course, and the practice of medicine in dishonourable hands could soon become a quagmire of immorality. On the other hand it is comforting to reflect not only on the high standard of medical morality, but also on the extent to which that standard is recognised by public bodies. Municipalities and offices know that a doctor's certificate is not to be bought for half a guinea or a guinea, and the person who tries to tempt his doctor to lie generally goes away with a flea in his ear.

PERSONAL.

Mr. J. F. Craig, M.B., of Birmingham, has been elected President of the United Kingdom Police Surgeon's Association for 1906-7.

Mr. C. H. Ballance will open the proceedings of the Medical Society of London for 1906-7 on Monday next with a presidential address.

The official announcement has been made of Dr. Diarmid Noel Paton's appointment to the chair of Physiology in the University of Glasgow, in the place of Professor McKendrick, who has resigned.

Mrs. Stephen Ralli has increased the memorial fund to the memory of her late husband, which she devoted to the endowment of a Pathological Laboratory in the Sussex County Hospital, to £20,000, and it is announced that an assistant pathologist will shortly be appointed in that institution.

The opening lecture of the Christmas Session of the London Medical Graduates' College and Polyclinic was delivered by Sir Henry D. Littlejohn, M.D., LL.D., Professor of Medical Jurisprudence in the University of Edinburgh, on Monday, October 1st, 1906, at 5.15 p.m.

Sir William Broadbent will deliver the annual oration of the Brighton and Sussex Medico-Chirurgical Society, at the Royal Pavilion, on Friday the 26th inst., at 3 p.m. The subject of the address is "The Combat with Disease."

The Royal Sanitary Institute.

A Provincial Sessional Meeting of the Institute will be held at the Royal Pavilion, Brighton, on Saturday, October 27th, at 11 a.m., when a discussion will take place on "Co-ordination of Measures against Tuberculosis." The discussion will be opened by Sir William H. Broadbent, Bart., K.C.V.O.., LL.D., M.D., F.R.C.P., to be followed by G. A. Heron, M.D., D.P.H., F.R.C.P., Louis C. Parkes, M.D., D.P.H., M.O.H, Chelsea, John Robertson, M.D., B.Sc., M.O.H., Birmingham, E. C. Seaton, M.D., F.R.C.S., M.O.H., Surrey, C.C., F. R. Walters, M.D., F.R.C.S., W. G. Willoughby, M.D., D.P.H., M.O.H., Eastbourne, and general discussion is invited. Dr. Newsholme will give a short account of local arrangements for the notification of phthisis, and the sanatorium training and treatment of patients.

A CLINICAL LECTURE
ON
THE OPERATIVE TREATMENT OF INTERNAL PILES.

By SIR CHARLES BALL, M.Ch., F.R.C.S.

Hon. Surgeon to His Majesty the King, Regius Professor of Surgery, University of Dublin, Surgeon to Sir Patrick Dun's Hospital.

IN order to satisfactorily operate for the cure of internal piles, and to avoid the unpleasant after-effects we sometimes see, it is necessary to have a clear understanding of the relations and functions of the structures which surround the outlet from the rectum. As pointed out by Ranney and Symington, the anus is not a mere aperture, but, in a condition of rest, is a definite canal about one inch in length, the lower three-quarters of which are covered by thin cuticle, while the upper quarter is covered by mucous membrane; between these is found the muco-cutaneous junction, which is usually somewhat irregular from the presence of the anal valves, and is known as the pectinate line or, formerly, Hilton's white line. The cuticular portion of the anal canal is arranged in vertical folds to permit of the necessary distention, and when the anus is examined with the margin slightly separated, these folds appear as the well-known radiating ridges. Similarly the

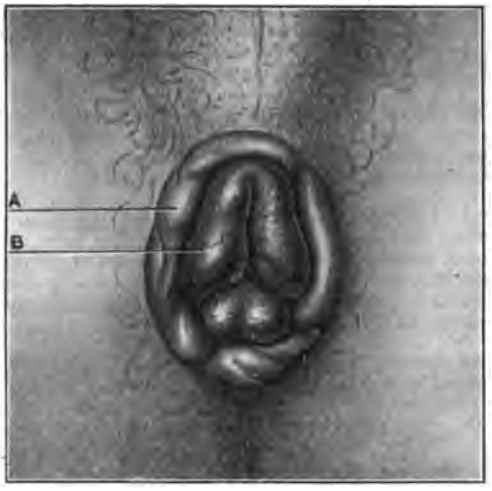

FIG. I.

Prolapsed internal piles. A, Revoluted Cuticular portion of Anal Canal. B, Prolapsed internal piles covered with Mucous Membrane.

mucous portion, likewise for the purpose of permitting distention, is arranged in vertical folds, the columns of Morgagni. In the passage of a motion the first act is the dilation of the anal canal and the obliteration of all these folds; the cuticular portion then becomes revolute so as to expose the pectinate line, or even some of the mucous membrane. When the anal canal closes after the motion has passed, the cutaneous portion involutes and the folds reappear. If piles are present in the mucous portion of the anal canal (the invariable site of internal hæmorrhoids), they protrude during defæcation; the highly vascular and delicate mucous covering is easily abraded, and bleeding takes place. If the piles are small they can be reduced again into the rectum by the combined action of the levator ani and sphincter muscles, but when of considerable size this is impossible, and they have to be pushed up with the fingers within the grasp of the sphincteric apparatus; when still more extensive they prolapse independently of the act of defæcation, and give rise to a great deal of annoyance. If a typical case of prolapsed piles is examined (Fig. 1), we see one or more protuberant masses in the centre covered with bright red, finely granular mucous membrane which bleeds upon but slight provocation, while round the circumference is seen an elevated ridge covered by thin cuticle, and between these the irregularities of the pectinate line are observable; this ridge is really the revoluted cuticular portion of the anal canal, usually somewhat hypertrophied. That this is the true explanation of the outer ring can be readily demonstrated by reducing the internal piles, when the

B, Internal pile covered by mucous membrane.
Between A and B the Muco-cutaneous junction with the Anal valves and pouches is well seen.

surrounding ridge can be seen to involute and the anus resumes its normal appearance. Certain variations from the above type are frequently met with. Internal piles which have been subjected to frequent prolapse, possibly for many years, undergo structural changes; they become less vascular, more fibrous, and the mucous covering becomes paler in colour and more like cuticle, while bleeding may have entirely ceased; the circumferential ring also undergoes changes from the formation of thrombotic external piles, and the growth of irregular tags of cuticle.

Choice of Operation.—It is only in the most trivial cases that any plan of treatment short of complete removal is worthy of serious consideration; chemical caustics, electrolysis, and such methods are only applicable to slight vascular excrescences of the mucous membrane where but little new tissue has been formed. If piles of any considerable size are present, some method by which they will be completely removed should be recommended. For this purpose many methods have been employed, excision, ligature, crushing, cautery, &c., while of each of these there are several sub-varieties. Good results have been obtained with all of these, while, on the other hand, the unpleasant sequelæ, hæmorrhage, stricture, incontinence, exposed mucous membrane, and quick recurrence of the disease, may occasionally be observed owing to faulty application of any of the above methods.

The conditions essential to satisfactory operation and prevention of these sequelæ are (1) complete removal of implicated mucous membrane with subjacent pile structure; (2) accurate hæmostasis; (3) avoidance of injury to the muscular coat of the rectum or external sphincter muscle; (4) while removal of redundancy is necessary, great care must be taken to preserve as nearly as possible a normal amount of the cuticular covering of the anal canal. I am satisfied that these conditions can best be fulfilled by the removal of each pile separately by an operation which combines some of the details of excision, crushing and ligature in the one operation. For the past seven years I have adopted this combination almost exclusively.

Method of Operating.—The patient having been anæsthetised to full relaxation of voluntary muscles, is placed in the lithotomy position, and the anus thoroughly dilated by the introduction of the two index fingers or thumbs, by means of which a strain is kept up upon the sphincters until complete relaxation has taken place; this should be done carefully so as to avoid extensive laceration. The piles now become prolapsed and generally more tumid, owing to extravasation of blood into the submucosa, the result of the stretching. An exact estimate is now to be made of the amount of tissue necessary to remove, and a hæmostatic catch forceps applied to each pile or piece of spongy mucous membrane requiring removal; four or five pairs of forceps are thus usually applied, and allowed to hang down in a cluster; in this way there is no danger when afterwards the parts become obscured by blood, of any of the smaller piles being overlooked or forgotten. Taking up one of the catch forceps now, by gentle traction the whole of the enclosed pile is made prominent, and its lateral attachments to the anal canal separated by nipping through with a scissors. Much of the success of the operation depends upon how this dissection is carried out, as already pointed out, prolapsed internal piles are surrounded by a ring formed by revolution of the lower zone of the anal canal, and between this and the piles proper there is found an irregular line which corresponds to the pectinate line or muco-cutaneous junction. If the dissection of the lateral connections of the piles is commenced at the pectinate line, as is commonly recommended, following the original description of Mr. Salmon, it will be found that although the revolution of the lower anal canal can be reduced, at the completion of the operation, it is apt to recur the first time the bowels move and become permanent in the shape of cutaneous tags (external piles), which give a good deal of annoyance and sometimes require a further operation for their removal. If, on the contrary, the dissection is commenced at the outer edge of this cutaneous ring, too much tissue will be removed and possibly an anal stricture will result, or, when healing has taken place, it will be found that a portion of mucous membrane has become permanently everted, which is a great discomfort to the patient from the moist mucous secretion which constantly soils the parts. It is obvious, therefore, that the proper position to commence the dissection is between these two lines, the best results are to be obtained by making a curved incision corresponding to the base of the pile being dealt with, taking care that the greatest convexity of the curve does not involve more than one-third of the cutaneous ring (Fig. 2), while the ends of the curved incision terminate in the mucous membrane at each side of the pile. By blunt dissection the pile is now separated from the external sphincter muscle, which is usually clearly visible, and must on no account be injured. The dissection is carried up the anal canal until the pile remains attached above only by healthy mucous membrane with the vessels coming down into it; this mucous membrane is now to be crushed in a powerful clamp. I prefer one with parallel closing blades; the line of incision is now to be carefully searched, and if any arteries are seen to be bleeding they can be twisted. A curved needle armed with strong silk is now passed through the sub-cutaneous tissue at a point corresponding to the greatest convexity of the incision (Fig. III.), and is next passed

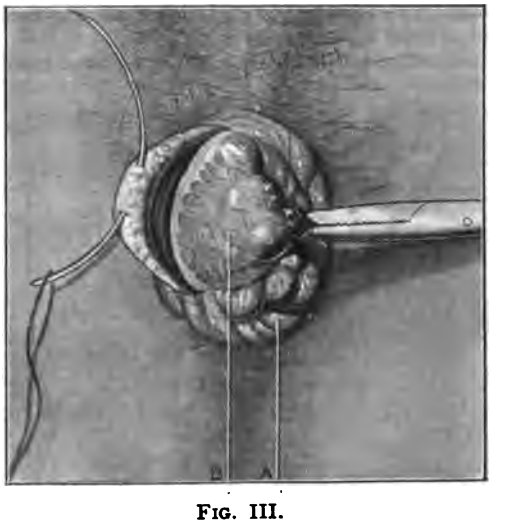

Fig. III.

The way to pass the needle through the subcutaneous tissue at the edge of the flap. The Sphincter muscle is seen deep in the wound, A and B, as before.

through the centre of the crushed mucous membrane forming the pedicle of the pile (Fig. IV.); this ligature is tied first on one side very tightly, thus strangulating one half of the already crushed pedicle, and the ends are then passed round and tied also very tightly on the other side, constricting the entire pedicle and including the half already tied (Fig. V.). The effect of this ligature

is to control the larger blood-vessels going into the pile, while at the same time, owing to its having a sub-cutaneous hold on the revoluted skin of the anal canal, it returns this into place and maintains it in position until union has taken place (Fig. VI.). The use of the crushing clamp is of importance in allowing more accurate application of the ligature and more certain hæmostasis. The pile is now

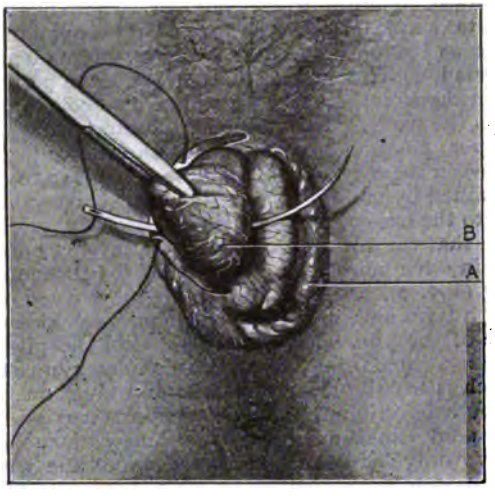

FIG. IV.

Passing the needle through the middle of the crushed pile, A and B, as before.

to be cut away in front of the ligature, but not close enough to endanger slipping, and the remaining piles to which catch forceps were attached at the commencement of the operation treated in the way above described. In the illustrations of this method, for the sake of clearness, the treatment of only a single pile is indicated, but it is to be understood that all are to be treated in like manner.

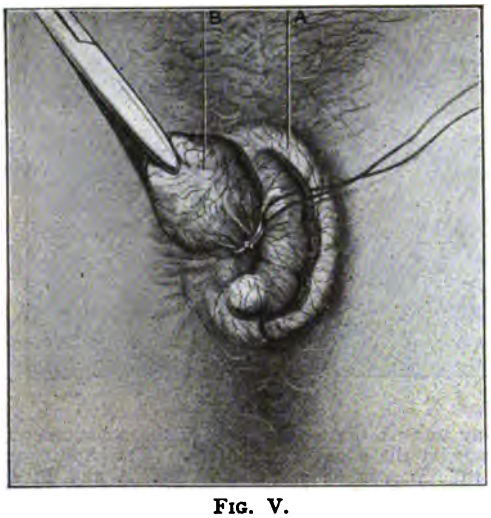

FIG. V.

The ligature completed, A and B, as before.

After-Treatment is usually simple ; the pressure of a gauze pad retained by a T-bandage in position appears to lessen painful spasm of the sphincters. The after-pain is variable. Occasionally trivial, it is frequently severe, requiring morphia for the first day or two. The bowels should be kept confined if possible, until the fourth day, when an aperient should be given. After the bowels have moved, the anus should be washed with weak lysol or other antiseptic, and if the ligature stumps are prolapsed, they should be gently returned within the sphincters. The ligatures should separate during the second week, and in about another week healing is complete. There is usually some inflammatory œdema, which generally subsides without trouble. If the same care is taken to preserve asepsis here as in other parts of the body, abscess or more severe

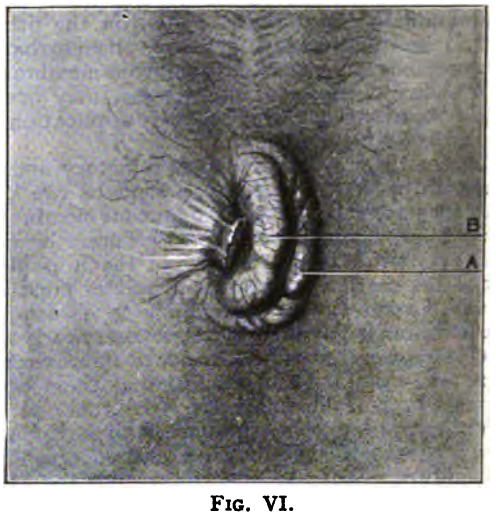

FIG. VI.

Showing stump left after ligatured pile has been cut away, and the way in which the flap of Cutaneous Anal Canal returns to its normal position.

septic complications are extremely rare, notwithstanding the necessary soiling of the wound. If just the right amount of skin has been removed the anus recovers completely its normal appearance and function. There may be a little bleeding the first few times the bowels move, and it is well to warn the patient not to be alarmed about it. Severe bleeding should not arise if the operation has been properly done, but if it should occur, possibly by the slipping of a ligature, it is better at once to give an anæsthetic, dilate the anus, and secure the bleeding point, and not waste time or give unnecessary pain to the patient by plugging or other such means.

NOTE.—*A Clinicol Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by Francis J. Steward, M.B., M.S.Lond., F.R.C.S.Eng., Assistant Surgeon to and Surgeon in Charge of the Throat Department, Guy's Hospital; Assistant Surgeon Hospital for Sick Children, &c., on "The Surgical Aspects of Tubercular Peritonitis." Lecture delivered at Guy's Hospital, May 25th, 1906.*

AT a luncheon given by the Lord Mayor of Liverpool on Monday last to Professor Ronald Ross, Professor Boyce, and Dr. J. L. Todd, in recognition of the decoration conferred on them by the King of the Belgians for their services in tropical research, Sir Alfred Jones read a letter from King Leopold stating that he had placed the sum of £1,000 at the disposal of the Liverpool School of Tropical Medicine, and holding out the promise of further pecuniary assistance.

ORIGINAL PAPERS.

ABSTRACT OF ADDRESS ON
THE GENERAL MEDICAL COUNCIL: ITS POWERS AND ITS WORK. (a)

By DONALD MacALISTER, M.A., M.D., Cantab., etc.

Linacre Lecturer of Physic, University of Cambridge; President of the General Medical Council of the United Kingdom.

Gentlemen,—To-day I propose to speak, informally but as I trust not loosely, on various matters concerning our common profession and its government with which it behoves us all to be acquainted, and about which many mistakes are made—for want of knowledge.

The General Medical Council has points of interest for students, practitioners, and laymen alike: and my only fear is that I may fail to make them as interesting as they really are. My chief difficulty lies in the misconceptions that exist regarding the Council's powers and its work. I seldom take up either a professional or a non-professional paper that touches upon medical matters without finding evidence of these misconceptions. Sins of commission, more often sins of omission, are freely laid to the Council's account, of which from its very nature and constitution it cannot be otherwise than guiltless. It is scolded for doing what the law says it shall do. It is bitterly reproached for leaving undone what the law gives it neither power nor means to do. It is spoken of at one time as the Parliament of the profession. Yet it has no authority to legislate for anybody, and it cannot make even a by-law for any but its own proceedings. At another time it is scornfully described as a "doctors' trade union." Yet it cannot legally levy an annual subscription, or say a word on the matter of rates of pay, or hours of work, or disputes with employers; it offers no pecuniary benefits or strike pay; and it *can* be sued in the courts like any other corporation. I venture to think that such a "union" would hardly be thought to deserve the name by the energetic organisers of Lancashire and Cheshire trades.

The Council is in fact neither a Parliament for making professional laws nor a Union for protecting professional interests. When the Council was created, nearly 50 years ago, the declared purpose of the Legislature was not to promote the welfare of professional men or professional corporations, it was not to "put down quackery" or even to advance medical science. The object in view was simply the interest of the public. The preamble of the Act of 1858 consists of two lines only: "*Whereas it is expedient that Persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners: Be it therefore enacted . . .*" The preamble, as you see, recognises two kinds of practioners, the "qualified" and the "unqualified." Up to that time no easily-understood line was drawn between the two, and when the public desired to make a choice, they were frequently at a loss. The Act set up machinery for, as it were, "hall-marking" the qualified practitioner, so that he might easily be recognised when his services were required. But the public were left free then, as they are free now, to seek "medical aid" from the unqualified practitioner if they liked. And the unqualified practitioner was left free then, as he is free now, to practise for gain among those who chose to employ and pay him. He was forbidden under penalties to pretend that he was qualified, by taking a title he did not possess; he might not use the courts for the recovery of his charges; he could not give a valid certificate of death: but except for these and a few other not very inconvenient disabilities he was untouched by the new law.

On the other hand, the "qualified" men, as a set-off to their new legal status and official recognition, were subjected to a new central control, educational and disciplinary. They obtained no monopoly of practice among the public in general. They were afforded no special "protection" against the competition, not always scrupulous or insignificant, of the uncontrolled unqualified practitioner. Indeed, for a time, those of them who were educated and licensed by medical schools and corporations were in a sense exposed to greater competition than before. For at the outset, all who claimed to have practised before a certain date in 1815, whether they had been educated or not, were enrolled among the qualified. In this way a number of elderly practitioners, who had no licence or diploma whatever, were accorded the same legal status as the rest, and practised side by side with them. These, of course, have now disappeared; but their existence must not be forgotten when we are considering the so-called "privileges" of the profession which were conferred in 1858.

The qualified practitioners might fairly have claimed that it would be good for the public, as well as for themselves, if monopoly of practice and protection against the competition of the untrained *had* been conferred upon them. In other countries, and in other parts of the King's Dominions, the restriction of practice to the qualified is with general consent and approval enforced by law. Any unqualified person who habitually and for gain practises or holds himself out as practising any branch of medicine is liable to severe penalties. But in these days of "Christian Science," and "Nature Cures," and "Bile Beans," it requires a good deal of optimism, and some resolute ignoring of the signs of the times, to believe that in this free (and easy) country legislation to that effect is either probable or possible in the near future.

The result, foreseen or unforeseen, of Acts passed since 1858 has been rather the other way. An unqualified *person* can be restrained from using a title, such as "physician" or "dental surgeon," which implies qualification and is reserved by law for qualified men. But if he takes to himself six other persons, as unqualified as himself, and registers the compound individual as a joint-stock company, it is held that, in England at least, he can call himself what he likes. He is no longer a "person," but a corporation—with the usual and highly convenient negation of soul or body. Thus the distinction set up by the Medical Act is blurred by the operation of the Companies Act. The public may well be excused if they think they are dealing with qualified practitioners when they seek advice at the establishments, legally incorporated, of "Dr. Galen Æsculapius Jones, Limited," or "Professor Smith and Co., Consumption Specialists," or "Tooths, Cash Dentists." Strenuous efforts have been made, within and without Parliament, to get this remedied; but so far without much success. The Legislature is in fact very tender towards unqualified practitioners of every kind—so long as they do not presume to practise *law*. The lawyers have seen to it that *that* profession at least is sacred.

I have mentioned that in 1858, when medical men were first officially registered, everyone who claimed to have been in practice some 40 years before was enrolled, even though he held no diploma or other certificate of competency. The vested right even of the unqualified was thus carefully respected. A similar thing happened 20 years later when dentists were enrolled, and to-day the *Dentists' Register* is made up, to the extent of nearly one-half, of men with no other qualification than "in practice before July 22nd, 1878." Four years ago, as the outcome of a bitter cry for the better regulation of midwives, whose want of skill and cleanliness brought suffering and death to countless mothers and infants, the Midwives Act was passed. Again all women went on the roll who applied, and had been in practice for a year—trained and untrained together. Those who did not choose to go on the roll were allowed two or three years more during which they could use the title of midwife, though unenrolled or uncontrolled. And not until 1910 will it be illegal for a woman, who is not enrolled and has no certificate

(a) Delivered at the Victoria University of Manchester on October 2nd, 1906.

of training, to practise for gain that perilous office—perilous I mean to those who place their lives in her hands.

All this care for the unqualified can, I have no doubt, be excused on political and legal grounds. That I am not concerned to deny. I mention it to illustrate the general temper of our lawgivers—and of their constituents also. We all of us in our hearts incline to distrust the rule of the expert, and we rather admire the amateur. Most of us flatter ourselves that in one way or another we are something of amateurs ourselves. It is more than a half-truth to say that England would rather be free, free even to let itself be injured or befooled, than under compulsion to be sober, or healthy, or secure. And so long as this mood prevails I do not see much chance for the Bill that is to "put down quackery" with a strong hand. Parliament may go so far as to "distinguish" the trained from the untrained practitioner: it will then leave you free to make your choice—at your own risk.

The instrument which Parliament set up for the purpose of marking the distinction is called the *Medical Register*. And the making and keeping of this Register is entrusted to the *Medical Council*. On the Register are placed the names of those who have passed certain tests of professional fitness. These are called *Registered Practitioners*, and these alone the law declares to be duly or legally qualified. The Council has to see that the tests of professional fitness actually applied by the Examining Bodies to aspirants for registration are "sufficient." They must ensure that those who pass them possess "the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery." The Council has also to see that no registered person who by crime or misconduct has become unworthy of the legal status which registration confers shall remain on the Register. In other words the two great functions which the Council in the public interest discharges are—first to prevent the unfit from gaining access to the Register, and, secondly, to remove the unworthy from it. Except as to a few subsidiary matters such as the preparation of the *Pharmacopœia*, the control of Diplomas in Public Health, the scrutiny of the Midwives' Rules, and the like, all its powers and all its work, in relation to the medical and dental professions, have reference to these two functions. It is a Council of *Education* and a Board of *Registration*.

It is a Council of Education; but it neither teaches nor examines. It cannot lay down a code or curriculum compulsory on all medical students. It cannot inspect a single medical school. Its statutory powers are strictly limited. It can order the visitation and inspection of the various examinations held by Universities and Corporations in the United Kingdom, for the purpose of testing candidates for their respective medical degrees or diplomas. And it can require from these bodies information concerning the course of study, and the age of candidates, which they prescribe. If from the inspection of the examinations, or the information supplied as to the curricula, the Council comes to the conclusion that either are "insufficient," it has no power to disallow them, or to order that they shall be amended. It forwards its report to the body concerned, takes note of any observations the body may make thereon, and if it is still convinced that the training or the test is "insufficient," it brings the question before the Privy Council.

In this and in other matters the Council is in close administrative relation with the Privy Council. If in anything the Medical Council neglects its duty, the Privy Council may formally direct that the duty *shall* be performed, and may in default itself perform it. In the case before us the Privy Council has power to supplement as well as to supersede. It can do what the Medical Council is unable to do. If it sees fit, it can declare that an "insufficient" diploma shall be no longer recognised as legally registrable; and, if circumstances alter, it can rehabilitate the diploma, and make it valid again.

The Medical Council is also a Board of Registration. In fulfilment of this function, partly by the force of necessity, and partly in virtue of the interpretation of the law by the Judges, it has become a Professional Court of Justice, a domestic forum for the trial and determination of grave charges brought against registered practitioners in their professional capacity. By successive judicial decisions it has been laid down that in its procedure the Council, sitting as a tribunal, must as nearly as possible follow the forms and rules customary in other courts. But it has no authority to compel the attendance of witnesses, to administer oaths, or to call for the production of documents. It has only one judgment to give when a charge is proved to its satisfaction—namely, "guilty of infamous conduct in a professional respect"; and only one sentence when judgment is given—namely, "erasure from the Register." From this sentence and judgment, given after proper inquiry and without malice, the High Court of Justice has pronounced that there is no appeal.

All the Act says is: "If any registered medical practitioner shall be convicted in England or Ireland of any Felony or Misdemeanour, or in Scotland of any Crime or Offence, or shall after due Inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such medical practitioner from the Register." In 1863 the Lord Chief Justice and his colleagues of the Queen's Bench laid it down that this clause "makes the Medical Council sole judges of whether a medical practitioner has been guilty of infamous conduct in a professional respect; and this Court has no more power to review their decision than they would have . . . of determining whether the facts had justified a conviction for felony or misdemeanour under the first branch of the section . . . The Council is the tribunal to whom the Legislature has left the decision, as being the best judges in the matter, and this Court cannot interfere."

In another appeal Lord Justice Bowen declared that, provided "due inquiry" had been made by the Council, "the jurisdiction of the domestic tribunal which has been clothed by the Legislature with the duty of discipline in respect of a great profession, must be left untouched by Courts of Law."

Referring to the language of the Statute, Lord Justice Fry added: "'Inquiry,' and 'judgment,' and 'guilt' are all words which express and which are relevant to a proper form of judicial proceedings, and therefore, although this body proceeds by different rules of evidence from those on which Courts of Law proceed, I cannot for a moment doubt that the Council were proceeding judicially; nor can I help adding that the manner in which the Council has proceeded on this inquiry, as on all other inquiries, shows that the Council are fully aware that they are performing judicial duties, and endeavour evidently to perform them in a very admirable manner."

These and like judgments settled the jurisdiction and the procedure of the Council sitting as a tribunal. The meaning and scope of the statutory verdict of the Council, "guilty of infamous conduct in a professional respect," were given by the definition of the Court of Appeal in 1892: "If it is shown that a medical man, in the pursuit of his profession, has done something with regard to it which would be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency, then it is open to the Council to say that he has been guilty of 'infamous conduct in a professional respect.'"

I have given these important decisions at length for two reasons. They show, in the first place, the position assigned by the law to the Council's judicial inquiries and the range of its jurisdiction. In the second they illustrate the process of legal development by which these words in the Act of 1858—"inquiry," "judged," and "guilty"—have inevitably led the Council to become a court of professional discipline, with duties and powers which were certainly not explicitly set forth in the Statute, if indeed they were implicit in the intentions of the Legislature.

More recently the practice of issuing objectionable advertisements or of employing or sanctioning the employment of canvassers with the object of procuring patients

was brought before the Council in connexion with particular flagrant cases. Each case had to be dealt with on its own merits or demerits. The character of the objectionable advertisements varied; in some cases the canvassing or touting was direct, in others it was carried on through the agency of a club or association or dispensary. Sometimes the case was strenuously fought, in others the accused practitioner preferred to discontinue the practice complained of and submitted himself to the clemency of the Council. Once more when the time was ripe, and the various forms assumed by the mischief were fully apprehended, a "warning notice" was issued as before. This pointed out the public detriment and professional discredit attaching to unworthy methods of attracting practice, and gave notice that practitioners who employed them, or sanctioned their employment, were liable to the penalty of erasure from the Register. A similar notice had already been issued to dentists, as the result of a series of cases duly heard and determined. In this instance the Council had the support of the Court of Appeal, given in a series of important judgments relating to an advertising dentist of some notoriety.

These examples, and I could add to their number, illustrate my statement that even with its apparently limited powers as a Court, and notwithstanding the apparent inadequacy of the Statutes which govern it, the Council does in fact formulate, and by formulation makes explicit, fresh applications of the law to the growing complexity of modern conditions. And, what is more important, in doing so it carries with it the consensus and approval of "professional men of good repute and competency." The average conscience is quickened, and what was once tolerated is in the end repudiated and discountenanced.

The experience of the Council on the judicial side of its work has been singularly paralleled on the educational side. There, too, positive *powers* that are seemingly meagre and inadequate have not prevented it from developing an *influence* which is real and potent.

Its powers only enable it to visit and inspect examinations, and to call for information as to courses of study: it is not authorised to prescribe or to amend either. It cannot itself disallow an "insufficient" curriculum or an "insufficient" test: it can only report its opinion to the Privy Council. These are the limits imposed on its educational action by the terms of the Medical Acts, and at first sight they are narrow enough. But in practice they have proved to be more efficient than they seem in theory; and the "long result of time" has gone far to make them adequate for the purpose. This result has been reached, as in the other case, by a gradual process of evolution, and by the exercise of moral pressure. It is dependent in great measure on three factors—one the constitution of the Council itself, another the loyalty and conscientiousness of the teaching and examining bodies, and the third the publicity of the Council's minutes and proceedings.

Let me say a little, first, about the constitution of the Council. As you all know, the testing of students in medicine, and the granting, to those who pass the test, of medical diplomas and degrees, have been entrusted by the State to Universities and to certain professional Colleges and Societies within the three kingdoms. Some of the Universities are of great antiquity and repute, like Oxford and Cambridge; others are modern and filled with high ambition, like Victoria and Birmingham. The professional Colleges of Physicians and Surgeons are all of considerable age, with traditions of service to the cause of medicine that extend over centuries. Altogether there are now 24 bodies that are legally entitled to test candidates and to confer diplomas. In England, and also in Ireland, two of the bodies, and in Scotland three, have combined for examination purposes to form three Conjoint Boards, one in each division of the Kingdom. But for all other purposes the bodies preserve their autonomy, and make their own regulations. To the fifteen Universities it is probable that a sixteenth, namely the University of Wales, will shortly be added.

Each of the 24 Licensing Bodies, as they are called, appoints a member of the Medical Council. Five members are appointed directly by the Crown, on the advice of the Privy Council, and five members more are appointed by direct election, under a universal suffrage, by the registered practitioners resident within the Kingdom. The total number of members is thus at present 34. Of these, 14 only are required by law to be medical practitioners themselves. The Crown and the Universities may appoint laymen if they like. They have not chosen to do so; but the freedom reserved to them illustrates what I have already remarked on—namely, that Parliament in creating the Council had in mind the safeguarding of general public interests, not of professional or scientific interests. In my own University of Cambridge, the member is elected by the Senate, *more burgensium*, that is, as the members of Parliament are elected. The Senate numbers over 7,000 graduates in all the faculties, and each has his voice and vote. When I was first returned to the Council I had, like better men, to pass through the ordeal of an election contest. The five members directly elected by the practitioners of the three countries were added in 1886. In 1882 a Royal Commission had reported as follows: "While we insist that the reason of the existence of the Medical Council is in the interest of the public, we cannot but recognise the vital interest of the whole Medical Profession in the constitution of that Body. It seems to us highly important that the Profession should have full and complete confidence in the Council, and seeing that the governing Bodies of the Medical Corporations, which now elect members of the Council [and which alone, be it remembered, are required to elect medical men] can hardly be said to represent the great majority of practitioners, we think it advisable to give the general practitioner an effective voice in the Body which will be the principal authority of the Medical Profession. We see no reason to suppose that the members elected by direct representation will be less eminent than those nominated either by the Crown or the [proposed] Divisional Boards" [of the three parts of the Kingdom]. The Commission accordingly recommended that four members should be directly elected, two for England and one each for Scotland and Ireland. The Act, when it came, was framed on a somewhat different basis, and gave three members to England instead of two.

Please observe the main reason alleged for the introduction of the directly elected members: it was "highly important that the Profession should have full and complete confidence in the Council." Exactly the same reason may be assigned for the arrangement, also sanctioned in 1886, by which each one of the Licensing Bodies was granted an effective voice in the counsels of the principal authority. For in their case also it was important that they should have such "full and complete confidence in the Council" as would make them ready to co-operate with it in matters of medical education. The new Act conferred no new coercive powers on the Council. Its numbers were increased, the extent of the qualifying examinations was enlarged and better defined, the scope and method of the inspection to which they were subject were more fully expressed. But the Council, as before, could only in the last resort report to the Privy Council any deficiencies it discoverer. The law, in fact, contemplated that reasonable uniformity and stringency in the existing tests were to be brought about, not by autocratic compulsion, but by common action for a common end. To use the language of a recent Bill, "peaceable persuasion in a reasonable manner" was to be the main motive force entrusted to the Council, so far as Medical Education was concerned. Ardent reformers cried then, and have often cried since, for speedier and more drastic powers. But, after all, is not the method adopted by Parliament characteristically British? "Government with the consent of the governed": "freedom limited only by necessary checks on the abuses which would destroy the freedom and efficiency of others." These are general maxims of our statecraft in regard to other departments of our corporate life. And the State thought well to apply them to the regulation of our profession also.

By its new constitution, then, in which (1) the State

on behalf of the people; (2) the profession itself; and (3) the several bodies which educate, test, and maintain the repute of the profession, possess each of them an effective voice, the Council became better adapted than before for its purpose of regulating the training of medical men. It became in fact a better *Council* of Medical Education. The duty and responsibility of appointing not obedient *delegates* but good *members* were imposed on each of its constituent bodies and sections. Their credit rather than their narrower interest was involved in the selection they made. For the influence wielded by any member of the Council within its walls ultimately depends on his character and capacity as a man among his brethren, and not on the dignity or power of the body which sends him. That influence is instantly weakened and discounted if he comes burdened with a mandate, or hampered by a pledge. He must be a voice, and not merely an echo.

I have said above that the *Constitution* of the Council was a factor in the development of its educational influence. I have given you a sketch of what the Constitution *is*. Let me next consider briefly how it reacts upon the Council's work.

As regards education, the principle sanctioned by the Legislature is that laid down by the Royal Commission of 1882. "It would be a mistake to introduce absolute uniformity into medical education. One great merit of the present system, so far as teaching is concerned, lies in the elasticity which is produced by the variety and number of educational Bodies. Being anxious not in any way to diminish the interest which the teaching Bodies now take in medical education, or to lessen their responsibility in that respect, we desire to leave to them as much initiative as possible. In certain matters of general importance, such as the duration of study, and the age at which a student should be permitted to practise, common regulations ought, we think, to be laid down; but we wish to record our opinion that nothing should be done to weaken the individuality of the Universities and Corporations, or to check emulation between the teaching institutions of the country." In other words, competition between a multiciplicity of teaching Bodies, as such, tends to the advancement of education. The institution which, *cæteris paribus*, affords the most efficient teaching will have the best reputation and be the most resorted to. The interest involved in the competition is the interest of improvement.

In so far, however, as the *primary* tendency of competing examinations might be regarded as downwards, rather than upwards, the State has established a check. It has affirmed the principles (1) that a certain minimum of stringency shall be required; (2) that the minimum shall always be such as to secure efficiency in the practice of the essential branches, and lastly (3) that, to admit of the gradual rise of the minimum with advancing needs and advancing knowledge, the practical definition of it from time to time shall be left to the General Medical Council with the concurrence of the Privy Council.

From the point of view of the Council as a corporate entity, it is also of inestimable advantage that each of its constituent bodies is represented upon it. Its members, in one aspect of their functions, are so many envoys from the Universities and Corporations. Each is in immediate touch with his governing body; he is by hypothesis in good standing and influence there, or he would not have been chosen. While he is an envoy *of* the body, he becomes in turn an envoy of the Council *to* the body. From his own knowledge of the course of the discussion, the arguments used, the examples proposed for imitation, he is in a position to explain and commend the Council's decision to his colleagues at home. He can make clear the scope and bearing of resolutions that are not always, I regret to say, self-explanatory.

The third factor I propose to mention to-day is the publicity of the Council's minutes and reports. About twenty years ago, in a notorious case, an attempt was made to restrain the Council from publishing its proceedings in relation to a penal inquiry. The attempt failed utterly. The "privilege" of the report in question was amply sustained. The Lords Justices of Appeal said: "The report is a report of proceedings which actually took place: proceedings within the jurisdiction of the Council: a report of proceedings where the facts had been ascertained: a *bond-fide* true report without any sinister motive: a report of a matter of public nature: a report of proceedings in which the public are interested, and in respect of which they are entitled to information." "We have come to the conclusion that the publication of these proceedings, being true, accurate, and *bond-fide*, is privileged."

Now if it is for the public advantage that proceedings relating to the character of a particular person should be published, it may well be held that it is still more for the public advantage that reports and proceedings relating to the action of a responsible corporation in the exercise of its public functions should have the like publication. Thus when one of the examinations has been inspected, the Inspector's report, with the remarks of the body concerned, and the remarks of the Examination Committee on both, are presented to the Council, and when duly received, are printed in its public minutes. The report is full and detailed, the strong points and the weak points of the examination are described and commented on, ample materials are furnished whereon to base the judgment of the Inspector, the Committee, and the Council, as to its sufficiency or insufficiency. The whole is discussed in the presence of the public and of the reporters of the various journals, and the decision can thus be criticised with knowledge of its grounds. The net result is certainly beneficial. If a body is commended for some new and valuable feature in its methods, for an examination-experiment which has proved successful, the commendation is public, and the credit of the body is enhanced. The other bodies have the opportunity of learning from the success of the pioneer body, and of adopting the improvements themselves. In this way a virtue is not only praised, it is propagated. It is twice blessed: it blesses the bodies that (thanks to their free initiative) were wise enough to discover or invent it: it blesses also the bodies that offer it the sincere flattery of imitation.

Time fails me to tell you in detail by what curious stages, through what disputes and controversies, along what educational bye-paths, the present arrangement has been reached. It is still transitional, there are still difficulties in the way, it is not yet perfect. But on the whole it is making for progress, for the uplifting of the educational status, and thereby the social status of the profession. And its improvement is fortunately the concern not of the Council only, but of medical men themselves. It is entirely to their credit that so many of them should be eager for a more rapid advance than the Council finds to be practicable. It has to carry a large number of bodies with it; the pace of the march has to take account of the slower as well as of the faster of these; and, as you know now, it has no real power to drive; it can only lead.

Let me make a last confession in closing. The Medical Council as an instrument of professional government is not ideally perfect. But it may be said for it that it did not start *de novo*, full-armed and potent like Minerva from the brow of Jove. Like every British institution it was built on old foundations of tradition and vested right and sacred privilege. It was not a creation but an adaptation. That it had within it, however, the seed of life, the germ of growth and expansion, my informal sketch of some phases in its half-century of history has, I hope, convinced you. Whether its future be one of continual evolution, or of sudden and complete revolution, it has not wholly failed in the task committed to it. The work it has succeeded in accomplishing has not been measured by the scanty powers it originally received.

CASES of fever continue to come into the hospitals of the Metropolitan Asylums Board with increasing rapidity. During Sunday and Saturday 160 fresh patients were removed from their homes, and the latest returns show 4,655 cases under treatment, 3,621 scarlet fever, 877 diphtheria, and 157 enteric fever.

PREDISPOSITION TO DISEASE, OR "MORBID IMMINENCE."

By P. LONDE, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY ABSTRACTED AND TRANSLATED FOR "THE MEDICAL PRESS AND CIRCULAR."]

Diseases, even of sudden onset, do not "break out" without a period of preparation, so to speak, of days, weeks, months, or, it may be, years. This preparatory period may be very protracted in chronic diseases, but it exists also for acute diseases, though it is then of shorter duration. In passing from health to disease we go through a whole series of præ-morbid stages, and a moment arrives when we find ourselves in a state of morbid imminence—the predestined victim of the first accidental cause that may present itself. During this preparatory process there is no disease, properly so called; localisation, at any rate, is still undetermined, and even its nature may remain uncertain. The change in health may not be manifested by any objective, or even subjective, sign, and if there be any prodromata, they are usually very vague.

We must, however, make a distinction between specific and non-specific diseases. For instance, from the moment when the incubation of measles commences, the nature of the disease is established; it will run a definite course, although its form is subject to variations. The evolution of certain other specific diseases, it is true, cannot be forecast with the same precision as in measles; nevertheless, the nature of the disease cannot change the moment the particular microbe has taken possession of the organism. Each microbe has its own peculiar mode of preparing the soil on which it will multiply if left undisturbed by any preventive treatment. The period of morbid imminence or predisposition, however, dates back anterior to infection. Even the receptivity of the subject may vary according to the state of the digestive organs and of the nervous system Disease always surprises the individual under cover of some nervous depression or digestive disturbance—indeed, these two factors are inseparable. The object of this article is, indeed, to demonstrate this fact in respect of non-specific diseases

That disease gains a footing under cover of these nervous and digestive factors is a statement that can hardly be questioned, whatever be the particular form that it assumes—bronchitis, pulmonary congestion, pleurisy, pneumonia, broncho-pneumonia, enteritis, appendicitis, rheumatism, gout, cerebral hæmorrhage, and so on. Diseases such as erysipelas, tuberculosis, and typhoid fever, though markedly less specific than the eruptive fevers, are due to exhaustion of an overworked organism quite as much as to the virulence of the specific microbe. The intrinsic cause dominates here, whereas in the truly specific maladies it cannot be said to exist.

The community of origin of so many very different diseases explains how it is that the physician prescribes repose and diet under so many and apparently opposite conditions. It enables us to understand the morbid equivalents that follow each other in the same subject, apart from diathesis, and it facilitates the treatment of the class of patients, so common in urban practice, who, though they do not conform to any particular pathological state, suffer from functional disturbances, respiratory, vascular, digestive, or nervous, premonitory troubles of a morbid state which will ultimately become defined and localised if rest and diet do not intervene in time.

It follows that the state of morbid imminence is not always latent. It may be manifested by a series of premonitory symptoms which only become prodromal when they group themselves in a characteristic manner. Headache, giddiness, noises in the ears, sleeplessness, diarrhœa, cough, epistaxis, etc., form a prodromal syndrome suggestive of incipient typhoid fever; yet any one of these symptoms separately is commonplace, and may be associated with any sort of affection—infection, auto-intoxication, etc.

There are two categories of symptoms of morbid imminence; some are common to a great many patients, others are peculiar to certain subjects previously suffering from a lesion or a functional disturbance of some standing. We will first of all discuss the common symptoms.

Nervous manifestations are perhaps the earliest of the precursory signs of a morbid state, especially in nervous subjects whose organic consciousness is comparatively highly developed. Side by side with the nervous subjects, by way of contrast, we must place those whose internal sensations are blurred, as in the aged and in alcoholics. It is in the latter especially that the state of morbid imminence remains latent. All forms of pain furnish a valuable indication, the significance of which is in proportion to its previous absence. Pain is a warning; it tells us that the normal equilibrium is disturbed—in short, it is a useful if troublesome symptom. The subject who suffers is better able to defend himself. This is a general law, applicable just as well to a whitlow as to pneumonia, enteritis or what not. Headache constrains us to rest the whole organism, particularly the abdomen, because it impels us to diet ourselves, and although it is often the sign of intoxication or general auto-intoxication, it is not unfrequently the outcome of some sympathetic abdominal trouble. Pain in the head, when unilateral, is often on the same side as the abdominal lesion. Right supra-orbital neuralgia may be associated with hepatic affections (biliary lithiasis), while on the left aide it is associated with disturbance of the stomach or sigmoid flexure.

Among the various kinds of backache, lumbar pain is the most important. We get it under many conditions—spinal meningitis, nephritis, lumbago, enteritis, Addison's disease, fevers, etc. Moreover, like headache, apart from any special indication, it signifies general fatigue, morbid imminence. The same may be said of undue sensitiveness to cold.

In addition to these early sensory troubles, there is a motor trouble that attacks patients long before the outbreak of actual disease—viz., asthenia with associated fatigue. In the psychical domain, somnolence and insomnia, irritability or depression, and especially anxiety, are not less characteristic signs of approaching illness. Some subjects on the eve of an attack of pneumonia, typhoid fever, or other affection, have a sort of presentiment that they are going to be ill. Others are seized with restless activity that makes them try and do several things at a time, as if they knew that this activity was about to be cut short, at any rate for the time being.

Alteration of the facies is a sign that may be associated with asthenia. The eyes become "hollow," and the features are drawn. The "seedy look" is but a rough sketch of the abdominal or influenzal facies. Internal suffering, even if unperceived, is reflected in the face, and even in the look. At the same time the complexion changes, becoming pale or yellow.

After all, these nervous disturbances are but the counterpart of what is going on in the digestive tract. There is arrest or vitiation of the digestive functions, and of the glands in connection therewith. Often the arrest is preceded by pre-morbid activity. Boulimia, for instance, may be met with on the eve of an attack of disease (influenza, articular rheumatism, enteritis, hepatic colic, etc), especially in the new-born. In the same way an exaggerated flow of bile may precede acholia or temporary hypocholia. This stage is followed by anorexia, with furred tongue, constipation, and abdominal distension. These symptoms are defensive acts, just as is the vomiting that may follow. In order to check this pre-morbid auto-intoxication, the organism suspends nutrition and arrests digestion. This is a sort of providential inhibition, because, as disassimilation is not being carried out normally for want of the necessary vital energy, assimilation is inhibited by mechanical control. It is then that the virulence of chance microbes comes into play, taking advantage of the diminished organic resistance. These phenomena are evident at the apertures of entrance to the respiratory and digestive passages for coryza,

sore throat, and stomatitis are due to infections of internal origin.

These are doubtless morbid manifestations that may remain isolated, but very often they merely herald some more deeply-seated affection, the localisation and nature whereof may not stand in any direct relationship to the initial infections. Thus the cough of broncho-tracheitis may prelude enteritis, pericarditis, or nephritis, just as much as a broncho-pneumonia; similarly a sore throat may proclaim the imminence of an outburst of rheumatism, just as much as of influenza or typhoid fever; or digestive disturbances may precede pleurisy, or catarrhal jaundice, or an attack of gout.

Consequent upon the digestive and nervous troubles, the general health suffers, and we get constitutional signs—plethora or anæmia, gain or loss of weight, pallor or congestion. Arterial pressure is modified in the sense that the standard of pressure is seen not to be the same under identical or analogous conditions in a series of subjects—in the subjects of arterio-sclerosis, for instance. In the latter a rise of pressure is essentially a sign of morbid imminence heralding an attack of cardiac hypertension (angina pectoris) or pulmonary (pulmonary œdema) or nasal or cerebral hæmorrhage. Arterial hypertension, like most of these precursory signs, is a defensive reaction, and the same may be said of hyperthermia, which is only an exaggeration of a natural process—in fact, it is in a certain measure a nervous reaction of which the intensity varies quite as much in relation to the individual as to the cause. In acute diseases, cardiac and renal determinations are usually secondary, and it will be sufficient if we point out the early signs that may present themselves—disturbances of cardiac rhythm and modifications in the urine. Tachycardia, brady-cardia, and arhythmia are in some instances premonitory or concomitant symptoms of distant accidents in the digestive area, the kidneys, or the brain.

The urine is the secretion that has been studied most closely in the evolution of disease. Now, in the majority of acute diseases, the results are approximately the same. During the terminal crisis the total excretion is increased, a phenomenon which is a natural corollary of the retention of waste during the attack. The important point to bear in mind in this connection is that the accumulation of waste matter precedes the disease proper, and that the auto-intoxication that results therefrom is the real cause of the disease. In this way we sometimes see a prefebrile discharge of urea, an effort on the part of the organism to avert the threatened infection. Many ill-defined temporary indispositions, characterised by complete inhibition of the digestive functions, accompanied by the asthenia which is its consequence, and the anxiety that is caused by suspension of organic life in any department, are manifested by an increased excretion of urea. What is true of nitrogenous waste holds good in respect of chlorides, and if, in pneumonia or influenza for example, the urine is comparatively poor in chlorides, this is due to the supplementary discharge in the expectoration, which is often rich in saline constituents. It may fairly be assumed that the phenomena which characterise the transition of disease into convalescence are the converse of those which prepare the way for the morbid process. Considered as the ultimate result of a pre-existing auto-intoxication, the disease tends to create a supplementary emunctory or to provoke a phase of extra activity on the part of a normal emunctory.

This view is confirmed by the study of the peculiar symptoms which certain subjects, already the victims of some taint, present during the period of morbid imminence. Persons, for instance, who have a periodical or permanent discharge, remark a modification in this discharge which warns them of the danger. Thenceforth the symptoms will vary according to circumstances, such symptoms being peculiar to this or that category of patients. These special symptoms consist in the exaggeration, suppression, or diminution of an abnormal emunctory already existing, called into existence by a previous malady. Bronchial catarrh, for instance, dries up at the approach of an attack of pneumonia; eczema retrocedes under the influence of asthma; anal fistula ceases to discharge in presence of tuberculosis of the lungs or pleura. In the same way we see the fœtidity of the expectoration or the urine increase on the eve of a fresh outburst of bronchitis or pyelitis, while, on the other hand, a hæmorrhoidal, nasal, uterine, or intestinal hæmorrhage may conjure the morbid evolution at its onset or prevent its appearance altogether.

In this way impending attacks of uræmia or cerebral hæmorrhage, typhoid fever, gout, or hepatic colic may be averted or deferred or arrested. By way of illustration we may mention the case of a young girl with angioma of the upper lip who was never ill, although pale and delicate, simply because she had periodical epistaxis. Preventive recourse to spring-bleeding or the use of setons is understandable, indeed recommendable, because it is unquestionable that a supplementary emunctory by hæmorrhage or suppuration turns aside the morbid proclivity from the deeply-seated organs and dispenses with the necessity for a disease, the object of the latter being precisely the establishment of a supplementary emunctory. This theory is especially applicable to rheumatism. In this case it is the serous membranes of the joints that receive the discharge of the poisons which the organism is endeavouring to get rid of. Salicylate of soda, owing to its action on the liver, checks the formation of these poisons, which, in respect of acute articular rheumatism, appear to be elaborated in the stomach. Disease, then, calls into being an additional eliminatory function intended to get rid of accumulated toxic products accumulated during the stage of morbid imminence.

Just as there are lesions and functional disturbances which ward off other accidents, so also there are diseases which create a state peculiarly favourable to the development of other maladies, thus constituting a series of morbid stages. The chronic enteritis of the new-born is the first stage of rickets; scarlatina places the kidney in a state of morbid imminence, just as acute rheumatism makes us apprehensive of the heart. A child who has suffered from bronchitis will be specially prone to an attack of broncho-pneumonia in the course of an attack of measles or whooping-cough. The gravity of a previous infection, as in cholelithiasis, will be increased in presence of any intercurrent infection. It would be easy to multiply such instances, but this is unnecessary except for the purpose of pointing out that repose and diet are always the necessary conditions of the preventive treatment of complications of diseases. The same means that enable us to avert diseases enable us to prevent their getting worse.

TRANSACTIONS OF SOCIETIES.

CENTRAL MIDWIVES BOARD.

MEETING HELD OCTOBER 4TH, 1906.

Dr. CHAMPNEYS, President, in the Chair.

AT the beginning of this, the Autumn Session, the chief matter brought before the Board was the answer to the Privy Council regarding suggestions made *re* amendments to the Rules as revised by the Board.

With respect to Poor-law Institutions, the answer was returned that the Board did not see its way towards recognising these as training centres.

Dr. CHAMPNEYS thought a certain number of cases essential. The resolutions referring to the number of cases were framed for their own guidance, and were of a tentative nature only. The Board did not wish them stereotyped, and hardly considered they were "Rules" requiring formal approval by the Privy Council.

Dr. Parker Young considered the Poor-law Institutions should be utilized, and less than six cases required.

Miss Paget remarked there was certainly no reason for not using the Institutions save that very frequently there was only one pupil for the teacher.

To the next suggestion—whether midwives should be compelled to notify births within forty-eight hours the Board returned answer that in their opinion the matter was one for legislation and not for a Rule of the Board. Also in answer to a letter from the Secretary of the Royal Commission on the Poor-law and Relief of Distress asking for a witness to give evidence as to the attitude of the Board in recognising such institutions, it was stated that the time was inopportune while the Rules were under revision.

Dr. Hope, M.O.H., Liverpool, wrote concerning the right of a midwife to advertize herself as an herbalist but at the Standing Committee it had been decided the Board possessed no power to interfere.

It was also agreed at the Committee to approve of the Government Maternity Hospital, Madras, as a training centre.

Mr. J. Cromie, L.R.C.P.&S., and Capt. A. E. Weld, R.A.M.C., were approved of as teachers under Rule C. 1 (3). On the Secretary notifying that among other refusals the name of Mr. Arthur Thompson, M.R.C.S., L.R.C.P., figured.

Dr. Parker Young rose to protest, saying Mr. Thompson was Medical Officer to the Newbury Workhouse, and attended all cases. The midwives there were very anxious for a teacher. When the application came up there were only two members present. He felt a great injustice had been done to the midwives in requiring them to come twenty times for lectures over sixteen miles at a 3s. fare. The Board was created to help the women to become competent. He wished, therefore, to move an amendment.

The President, in agreement with an argument often used by Sir William Sinclair, said it was not desirable to multiply teachers and lower standards; that it was understood at the time of decision that the nearest centre was near enough, and they could not establish centres within ten minutes of everyone.

Dr. Parker Young's amendment had no seconder, and therefore was lost.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Tachycardia. Blood-pressure.

By Leonard Williams, M.D., M.R.C.P.

This young man, æt. 24, first came to the Hospital during my absence. I find on his paper that he was then suffering from tachycardia, and that his pulse tension was high. It may be worth while to consider for a moment what we mean by tachycardia, and what we mean by pulse tension, taking the latter first.

Pulse tension, arterial tension, and blood-pressure are all used as synonymous terms. It is a pity that this should be so, but as it is so, we may accept the fact and use them indiscriminately. Now the person who made this note regarding the pulse tension of this patient probably meant his blood-pressure. One would like to know how he arrived at the conclusion which he records that this blood-pressure was high. If he had used an instrument, we may assume that he would have noted the exact measurement of the blood-pressure so recorded. If he did not use an instrument, then his opinion as to the state of the blood-pressure is practically valueless. There are people who, after feeling the pulse with one hand, will make a very definite and confident statement as to the state of the blood-pressure. I have heard a physician chide a student for doing this, and he proceeded to demonstrate to the student the proper way of ascertaining the arterial tension. This was by compressing the pulse with the finger of one hand, while the index finger of the other hand felt for the disappearance of the pulsation. Such a method, I may point out, is valuable in ascertaining the compressibility of the pulse, but you must remember that the compressibility of the pulse is in many cases no gauge whatever of the state of the arterial tension or blood-pressure. Only two days ago I found in a gentleman who came to consult me as compressible a pulse as I have ever felt, and yet his blood-pressure as registered by the Hæmomanometer reached no less than 200 mm. of mercury. Do not assume, therefore, that a compressible pulse necessarily indicates a low blood-pressure. Moreover, when we speak of blood-pressure we ought to distinguish between systolic and diastolic pressure: for, as you know, there is one condition, namely, uncomplicated aortic regurgitation, in which the systolic pressure is high and the diastolic pressure is low. A note, such as we find on this paper, then, to the effect that the pulse tension is high, is absolutely valueless. If you want to study blood-pressure you must use an instrument, for, as Professor Clifford Allbutt has pointed out, it is as futile to talk about blood-pressure without the aid of an instrument, as it is absurd to discuss temperature in the absence of a thermometer.

Now as to the other matter. What is tachycardia? Tachycardia indicates a quick pulse, but, surely, if we sound the pulse of a man who has been running a mile race, and find it beating at the rate of 150 or 160, we should not be justified in describing that person as suffering from tachycardia. To merit such a term the condition of rapid pulsation must be sustained, at least relatively, under varying circumstances. Now this young man, as he stands, has a pulse of 150, but if we lay him down and make some slight pressure upon his abdomen so as to empty his splanchnic vessels, we find that in the course of a few minutes his pulse rate falls to 90. Now that is not a condition which is justifiably described as tachycardia. Real tachycardia you will find exhibited in Graves' Disease. You will find it in commencing loss of compensation in valvular disease of the heart and in many other cardio-vascular conditions. You will find it—and this is a point upon which I should like to insist—you will find it as an early symptom in pulmonary tuberculosis. That is what is known as a "tip," and it is a valuable one. The real tachycardia, that is to say, the increased pulse rate which is not produced by exercise, by posture, or by other conditions known to influence the pulse rate, is very often due to commencing tuberculosis.

Now, if this young man is not suffering from tachycardia, what is the meaning of his increased pulse rate in the upright posture? You may satisfy yourself that his heart is in a perfectly normal condition. It is not enlarged, the sounds are normal in intensity and in rhythm, and there are no murmurs. In the recumbent posture the heart is, as it were, well within its stride. As soon as we get the patient up and walk him about, it seems to labour. Why should it do this? The reason is obvious if you will consider for a moment the factors which commonly influence the pulse rate. The greater the resistance to the blood flow, the more slowly and more powerfully does the heart beat. If you lessen that resistance the number of the beats increases. Now, given the fact that the heart is sound, we must look to the arteries for an explanation of this instability of the pulse rate. If the arteries are tightly contracted, the heart will beat slowly, in most cases at any rate. If, on the other hand, the arteries are dilated, the peripheral resistance to the blood flow is lessened, and a quickened rate is the result. The blood stagnates in the dependent portions of the body, and an insufficient amount of fluid reaches the heart. This I believe to be the state of matters here, and I feel confident that if we give this young man drugs such as strychnine and ergot, which are known to increase the contractility of the peripheral arteries, we shall relieve him of his so-called tachycardia and of the many unpleasant subjective symptoms of which he complains.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

EXPLORATION EIGHT WEEKS AFTER OPERATION FOR APPENDIX ABSCESS.—Mr. EDRED M. CORNER operated on a boy, æt. 10. Whilst the child was being anæsthetised, Mr. Corner made the following remarks:—He said that the case was a very unusual one. Eight weeks ago, the boy was operated upon for an appendix abscess on about the tenth day of the illness. An incision was then made, the right rectus abdominis split, and the peritoneal cavity opened. A tumour at once became obvious, with the intestines pushed to the left. The peritoneal cavity and pelvis could be easily examined, as there were no adhesions. In fact, the tumour was really behind the peritoneum, such as was taught to be common in former years and now is known to be rare. Almost every appendix abscess was, he remarked, primarily intraperitoneal. The peritoneal cavity was carefully packed off with gauze and the abscess drained. Previous to operation, the boy had presented in a marked degree a symptom uncommon in dealing with appendix abscesses. He had a constant and profuse discharge of mucus from a patulous anus! In a small degree, Mr. Corner pointed out, this symptom can be noticed when the abscess is in Douglas' Pouch, and is pointing in the rectum. But in the boy's case the abscess was by the brim of the pelvis and was not pointing. What, then, would have caused the discharge and the patulence of the anus. He believed it could only have been one thing—thrombosis of the superior hæmorrhoidal or rectal vein or veins, as they lie in the mesentery of the lower part of the pelvic colon. This, however, was a very unusual condition. He added that the mucus was sometimes blood-tinged. Suffice it, he said, that the boy was much relieved by the operation. and the mucous discharge diminished, but it did not cease, and neither did the temperature come down. Ten days later, an extra-peritoneal incision was made in the left iliac fossa into a cellulitic mass of subperitoneal tissue. No definite pus was seen. This incision gradually brought the temperature down and stopped the discharge of mucus from the rectum. But the convalescence had been very slow; a Widal reaction was negative. The boy had a septic rash and sore throat resembling scarlet fever, and pains, with a little fluid in his joints. These got well spontaneously. Within the last few days his temperature reached normal, and after being there two days rose to 104°, and he had abdominal pain and diarrhœa, the stools containing blood and pus, not unlike the maroon-coloured pus of a liver abscess. The temperature has now declined, and Mr. Corner was going to examine him under an anæsthetic to ascertain if the source of the pus per rectum could be found. There was no doubt that an abscess cavity had discharged into the bowel, but whether it was a secondary liver abscess, a cæcal abscess, or one due to some necrosis of the bowel associated with the thrombosis, could not be said.

The examination, which was at present carried out under the anæsthetic, revealed nothing, and Mr. Corner said that it only remained to watch the case and to attack whatever might turn up. He thought that this was a most unusual and interesting case of appendicitis associated with an extraperitoneal abscess, pelvic cellulitis, thrombosis of the lower part of the inferior mesenteric vein or veins, surgical scarlet fever, multiple arthritis, and a secondary abscess of unknown situation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 7th, 1906.

TREATMENT OF CHRONIC CONSTIPATION.

HABITUAL chronic constipation without any organic lesion is a very common affection, and for that reason, says Prof. Hirtz, is frequently passed in silence. If numbers of persons do not suffer from it, others no less numerous are exposed to all kinds of malaise and troubles, consisting of headache, vertigo, sleeplessness, anorexia, furred tongue, dyspepsia, slight colics, scybalæ (coprostasis).

Generally the patient himself draws the attention of the attendant to the condition of his intestine, whereby diagnosis is rendered easy and the treatment clearly indicated But often enough in general practice the troubles due to coprostasis are found to be somewhat more complicated than those already mentioned, and, if not recognised, might lead to error in the diagnosis.

Besides, constipation does not alone provoke purely functional or mechanical signs, but also general symptoms under the influence of auto-intoxication resulting from the absorption of the noxious products due to fermentation of the intestinal contents.

To these phenomena of constipation are added consequently symptoms of stercoræmia, the patients are poisoned, and this auto-intoxication can be pushed so far as to give rise to most fantastic diagnoses.

Coprostasis is accompanied by abdominal *pain*, variable as to its seat and intensity. All the abdomen may be painful, spontaneously or to palpation, but frequently it is localised in the large intestine. Predominating over the cæcum, it simulates appendicitis, and frequently that diagnosis has been made and an operation discussed. Localised in the right hypochondrium, at the angle of the ascending and the transverse colon it has been mistaken for cholecystitis. Seated in the epigastrium, the pain may be thought due to gastric ulcer or other painful affection of the stomach.

None the less interesting are the *radiating* pains which are felt over the thorax, in the loins and down the limbs, leading one to suppose the existence of intercostal neuralgia, renal affections, or sciatica. When patients complain at the same time of a sensation of fatigue and relative difficulty in walking, the consulting physician should be on the look-out for constipation.

A symptom to which M. Hirtz attaches great importance in coprostasis is the condition of the tongue. The tongue is large, thick, and dirty, covered with a yellowish fur and accompanied with very foul breath, especially in the morning. The patient who suffers from this fœtid breath suffers also from anorexia, accompanied by nausea and sometimes by vomiting, with distension of the stomach after eating.

The fœtid odour is a source of great annoyance, but can be removed by scraping the coating off the tongue twice a day with a hard tooth-brush and using a wash of diluted oxygen water.

Besides these symptoms more directly in relation to the digestive tract, there are others, although indirect, none the less a consequence of chronic constipation, as acne and urticaria.

Psychic phenomena are almost constant in this affection. Sometimes the character becomes irritable, the patients get angry for the slightest cause, everything annoys them, and their society is not agreeable. More frequently they are depressed, taciturn; they are unequal to all work and efforts at distraction. They lose pleasure in living, yet they are in constant fear of dying, or, on the contrary, they entertain ideas of suicide.

The most striking symptom of auto-intoxication is *emaciation*. Frequently a doctor is consulted by persons who have lost all their strength, have become

anæmic and grown thin in very notable proportions—15, 20, 30 pounds, or more. At first sight these persons would seem to be suffering from some cancerous affection or latent pulmonary tuberculosis, whereas they only require intelligent treatment of their chronic constipation to regain their usual health and vigour. A last symptom of coprostasis is *fever*, which is generally intermittent, and varies between 100° and 102°.

In the treatment of chronic constipation, M. Hirtz excludes all drastic purgatives, which are dangerous, and prescribes oils, castor oil or olive oil, with large enemas (one or two quarts) with luke-warm boiled water.

Attention should be paid to the alimentary régime. Meat, eggs, milk, cabbage, should be forbidden for a time and replaced by farinaceous foods, mashed potatoes, and a few green vegetables. When the health of the patients admits it, they might have recourse to the warm douche, and if their social condition afforded it, they might complete their cure by a visit to Chatel-Guyon.

GERMANY.

Berlin, Oct. 7th, 1906.

The *Deutsche Med. Zeitung*, No. 76, contains a reference to an article by Dr. L. von Aldou on

The Digestion of Fat in the Stomach.

The investigations were carried out by a careful analysis of a portion of the contents of the stomach taken an hour after the ingestion of an Ewald-Boas test breakfast. The whole acidity, free hydrochloric acid, the quantity of pepsin and the units of ferments were accurately calculated. These investigations show that the fat-splitting properties of human gastric juice was really still to be determined. The degrees of fat-splitting showed essential differences, whilst at the same time, no explanation of the reason for the difference could be ascertained.

The author felt justified on the basis of his experiments only in a simple statement of facts that smaller or larger quantities of emulsion are obtained; but these examinations do not justify any further conclusions. It is very unlikely—if a fat-splitting ferment really exists in the stomach—that this takes place quite independently of the other factors. The fat-splitting brought about by the author and his assistant was really not the work of a ferment, but a result of bacterial activity was not proved, but considering the great difference observed and want of any explanation of them, this possibility must be kept in reserve.

The justification of this standpoint was shown clinically by annual experiments carried out in Kunkel's Würzburg Institute. The fat-splitting of kittens fed freely with fat was so small when killed after a certain time that the whole process could be said to be free of both free acid and bacteria. At present we are not justified in speaking of any digestion of fat taking place in the stomach as being of a fermentative nature.

Prof. Umber and Dr. Th. Brugsch, of the City Hospital, Altona, discussed.

The Digestion of Fat in the Intestinal Canal with Special Reference to Fat-Splitting,

in the *Arch. f. Experim. Pathol.*, 55, 2 and 4.

The fermentative fat-splitting in the alimentary canal is by no means all cared for by the pancreas. Besides the fat-splitting ferment of the stomach (unquestioned by these authors) and the insignificant bacterial splitting which in the absence of intestinal juice in the bowel, in consequence of isolated pancreatic disease, cannot prevent the normal splitting up of fats, there is still another series of organs (liver, spleen, intestines, bile and blood) that are so important that they can almost equal the fat-splitting power of the pancreas. All these juices stand in many-sided and interchanging relation to each other, sometimes accelerating sometimes retarding, varying according to the kind and stage of digestion.

In this way it is explicable how in isolated pancreatic disease the fat-splitting may go on to a completely normal extent. Where, however, a portion of the intestinal tract becomes implicated in the disease of the pancreas (to any considerable extent) the fat-splitting powers of the intestinal canal must suffer.

Peritoneal Absorption.

A great deal has been written on this subject, and it has again been brought to notice by experiments made by Dr. K. Freytag, of the Royal Chir. Univ. Klinik, Bonn, the results of which have been published in the *Arch. f. Pathol. v. Pharm.*, 55, 4 and 5. The results were the following:—The resorption or the excretion of a solution of milk sugar did not run parallel to one of potassium iodide, the first being all excreted in at least twelve hours, whilst in the case of the iodide a positive reaction was obtained even at the end of twenty-four hours.

In severe and moderately severe cases of peritonitis resorption is slowed from the first or second hour.

In mild cases the absorption was accelerated during the first two hours.

Adrenaline retarded the absorption of a solution of milk sugar. In inflammation running a chronic course as well as in the case of abscess cavities, the absorption is slowed, but only slightly so.

A similar subject is discussed in the *Zeitsch. f. Chir.*, 82, 3 and 4, by Dr. P. Glimm, of Greifswald. His conclusions after investigation are as follows:—The absorption of substances soluble in water and probably also corpuscular elements, is accelerated by bacterial infection.

The view that absorption in advanced peritonitis that leads to death is impeded is not correct.

Olive and other oils check in a high degree absorption in peritonitis caused by bacterium coli, and the oils are well borne by the peritoneum.

The checking and slowing of absorption of bacterial fluid acts favourably on the course of the disease.

The origination of a peritonitis is not favoured by a check to absorption of fluid, but by an acceleration of it.

The investigator was well aware that a purulent peritonitis such as is met with in the human subject, could not be set up in animals for experimental purposes, but it is only through experiment that we can learn to understand the changes that take place during an attack of peritonitis. He is of opinion that the injection of olive oil would have an effect on the human subject, and in a desperate case after other remedies have failed, he would not hesitate to inject 130 ccm. of 1 per cent. oily solution of camphor. Chronic abscesses from which bacterial absorption takes place for weeks together might be treated in a similar way. No harm can be done, but, on the contrary, possibly much good. The writer, in the present state of our knowledge, would not dream of prophylactic oil injection. He also suggests the possibility of the injection of oil also being useful in joint suppuration and collection of pus.

AUSTRIA.

Vienna, Oct. 7th, 1906.

Aortic Valvular Disease and Syphilis.

Ryba, at the Prague meeting, related his experience in the exhaustive examination of 65 cases of aortic insufficiency. The ages of these varied from 30 to 40 years of age, but the most singular combination was the history of syphilis in every case, and the constant absence of rheumatism, chorea, angina, &c. Eight of these cases were examined in the *post-mortem* room, and were pathologically found to be chronic aortitis associated with what we recognise as gummatous deposits. The first changes appeared to be dilatation of the ascending aorta, and consequently to insufficiency of the valve; in very few cases were the valves sclerotic themselves. The first symptoms appeared about fifteen to seventeen years after infection with the syphilitic virus. It might also be added that

18 of these cases suffered from oculo pupillary symptoms; 6 from tabes, and the others from other severe psychical phenomena.

Thomayer remarked that his experience in these cases was that they were first attacked with angina pectoris, and later with the symptoms of aortic insufficiency. The cause of the early appearance of the angina was probably due to the structural changes in the aorta followed by sclerosis and degenerative changes in the vagus.

Sambesger thought the practical result of this investigation should lead us to treat such cases with anti-syphilitic remedies in the hope of modifying a chronic intermitting virus.

ATROPHIA SYMPTOMATICA.

Peta reported two cases of symptomatic atrophy arising from intestinal catarrh. The first was a child æt. 9 months, and weighing 5½ kilos, or 12.1 lbs.; the second, æt. 5, weighed 7½ kilos, or 16 lbs. By a perfect change of diet and careful nursing both of these children were restored to health. The first step was to abandon milk at once and adopt one of the many foods on the market at the present time as a substitute. Along with this, Rejtarek's Malto bath is an invaluable adjunct in the treatment.

EXTIRPATION OF THE BLADDER.

Pitha recorded his experience in a woman, æt. 70, who suffered from incontinence owing to cancer in the viscus. She suffered great pain, associated with hæmoptysis, which induced him to operate. He removed the bladder and attached both ureters to the wall of the vagina; but no urine came from either of the ureters in their new position, and the patient died next day.

At the *post-mortem*, the right kidney was found to be entirely destroyed by tubercle, and the left greatly enlarged, which pressed on the ureter below and caused a damming back of the urine in the pelvis of the kidney with dilatation and uronephrosis. The papillæ were flattened, but no abscess was found, while the urine was so decomposed and thick that it would not pass along the ureter. It is interesting to note that no trace of tubercle could be found in the left kidney.

MYXŒDEMA.

Sieber related the history of a case of myxœdema he treated with the thyroid extract with a little improvement. The œdema began in the eyelids and extended over the face. Next the hands and fingers began to swell, perspiration cease, hair to fall out, hearing grow dull, and the mind to become weak. The tongue at the present time is thick and the speech indistinct. The thyroid gland is very small, skin dry, while the hands and feet are greatly swollen; temperature 36° Cent., and pulse 72.

CHOLELITHIASIS.

Peigerova next discussed the ætiology of gall-stones, and quoted two series of cases he prepared in his investigations. His first comprised 14 cases of females, where the disease affec ed different phases of life, but particularly during the gravid period.

The second series, 24 cases, were all associated with the excess of saccharine matter in the dietary, which he considered the incontrovertible foundation of cholelithiasis.

ITALY.

Levantine Riviera, October 7th, 1906.

WHILE the names of health and pleasure resorts on the French Riviera are, to most people, as familiar as "household words," and even places on the Italian portion of the seaboard, which extends from Ventimiglia to Genoa, are fairly well known, yet, strange to say, though many hundreds of English travellers pass every year along the eastern Italian Riviera on their way to or from central Italy, this picturesque coast, with its interesting inhabitants, remained until lately very much as a sealed book to the majority. Correctly, this Riviera is considered to extend from Genoa, southwards to Leghorn, but that portion from Genoa to Spezia concerns us mostly. Here there are various resorts well worthy of attention, all easy of access, some already much frequented by travellers and invalids, who have discovered the beauty of this coast, who are attracted rather than otherwise by its quieter social atmosphere, and who, if they find some of the resorts a little more primitive than those on the French Riviera, find also the advantage that they are less expensive. Besides this, there are climatic differences which to many people are definitely advantageous.

Of all the stations on this sea front, fifty-six miles in extent, those at either end are the most important. Genoa is, of course, well known to every traveller, but it is not a favourite with invalids, apt as it is to be cold and draughty. Spezia, on the other hand, has for many years been something of a health resort, much frequented by English travellers who have been in the habit of making a short stay there *en route* for Florence or Rome, or of remaining for a longer time.

The other places immediately situated between Genoa and Spezia were, until recently, very imperfectly known, and are still so, though Rapallo, which has increased somewhat rapidly, is an exception, the number of its English visitors now being considerable. Taken in order from Genoa southwards, the chief resorts between that "city of palaces" and Spezia are Nervi, Rapallo, St. Margherita, Portofino, Sestri Levante and Levanto. The purpose of this article is not so much to specify the relative advantages of these places individually but collectively in their climatic conditions, and these, broadly speaking, do not differ greatly from the other and better-known resorts on the western Riviera. Both Rivieras are characterised by the proximity of mountains and sea, with a narrow band of land intervening, but extending inland here and there where the mountains are encroached upon by valleys which terminate seawards in small but picturesque bays, and where for the most part are the small towns which are developing into health resorts.

The mountains facing towards the mid-day sun form a barrier against the colder winds, and absorb much heat from the sun's rays, which heat they throw off again during the night, so that the atmosphere, warmed also by radiations from the surface of the sea becomes of an average temperature about ten degrees higher than in England. At the same time there are many more sunny days and fewer cloudy ones; while associated with this condition is the fact that there are constant alternating currents of air, between sea and mountains, resulting in a mild but fairly bracing climate, causing a slight stimulation and increase of bodily vigour.

Along the east coast there is undoubtedly more rain than westwards. Nevertheless, the relative humidity is said not to be high, and against the fact of a greater rainfall may be reckoned a more luxurious vegetation, less dust on the roads, and a softer atmosphere, which is fully appreciated by people who cannot sleep in too dry and exciting an air, also by invalids with bronchitic and asthmatic troubles; such people also rejoice in the absence of the cutting mistral, which is not experienced on this coast.

It should be remembered that here, as on many parts of the Mediterranean shore, the contrast between sunshine and shade is great, and the cooling of the air at sunset necessitates continual watchfulness, so that invalids should never be without easy access to warm wraps; and those who pass the winter in the Riviera should take with them warm clothing, since if a north wind blow—even though its force be broken by the Apennines—and snow fall upon the mountain sides, the temperature even on the seashore will be considerably lowered.

It is scarcely necessary to indicate the complaints which are likely to receive benefit from a stay on this coast, and from climatic conditions such as those which have been described. It is evident that all those requiring a mild tonic treatment, with a combination of mountain and sea air, the proximity of pine woods, a temperate climate, and non-irritating atmosphere, will probably grow stronger and better during their

sojourn in the eastern Riviera, but pulmonary tuberculosis is better combated at a greater altitude; moreover, your Italian hotel proprietor, as a rule, looks askance at sufferers of this type, and gives them but a poor welcome.

It should be mentioned that the season extends from October or November till June, the best months being April and May.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

The Health of the City, and the Medical Officer of Health.—As reported in this column last week, the much discussed appointment of a Medical Officer of Health for the city was made on October 1st, Dr. Bailie being the successful candidate. This appointment was first suggested as probable in this column nearly a year ago, when Dr. Bailie retired from the Corporation, with, as we then suggested, the object of qualifying for the post by the necessary six months' absence from that body. It was generally recognised that a job was contemplated, and strenuous opposition was raised by the Citizens' Association and other public bodies. Dr. Bailie was the nominee of the so-called "old gang" in the Corporation, a party in which jerry-builders and property owners and their hangers-on are prominent. The chairman of the Public Health Committee must be held largely accountable. He is an elderly medical man of private means, who finds his amusement in the duties of this office, but unfortunately the city has to pay dearly for his entertainment, the death-rate being among the highest in the United Kingdom. If he had taken a strong line in opposition to this appointment it could never have been made, but he allowed himself to be used by the "old gang" to promote their own private ends.

The matter is by no means done with, however. A strongly worded manifesto has been published by the Citizens' Association, and efforts are to be made to procure a Royal Commission to inquire into the health of the city, and questions connected with it. Though it is doubtful if the Local Government Board has any power to veto the appointment when their regulations have been complied with, a strong protest has been lodged with them against it. The manifesto gives again the names and full qualifications of the six candidates for the post put on the short list, all of whom appeared before the Corporation on October 1st. It then goes on to say: "Of these the final vote was cast in favour of Dr. Bailie, and the following facts are especially to be noted:—(1) That of the six candidates, five had previous expert experience as public medical officers of health. (2) That the same five had medical degrees of more or less distinction from the universities. (3) That the sixth and elected candidate, had no previous experience as a medical officer of health, and that he had no medical degrees from a university." The voting is then analysed, and the thirty-two men who supported Dr. Bailie are named, with a note as to those who retire from the Council next January. There is no doubt that the names will be remembered when the elections come on.

The Typhoid Outbreak.—Some fifty-five cases of typhoid have now been notified in the Windsor district of the city, and several deaths have occurred. The district is one of the best in the city, and many of the cases are in isolated houses standing in their own grounds. The sanitary authorities have stated that the outbreak is not due to defective sanitation, but to other causes. Concerning these other causes, however, they maintain a discreet silence. It is commonly reported that they are due to contaminated milk from one dairy, and if this turns out to be the case it will greatly strengthen the hands of those who have for years advocated the proper inspection of the dairies supplying the city with milk.

Supposed beri-beri in Belfast.—A Norwegian barque arrived in Belfast last week from Bangkok, with a cargo of teak-wood. It is reported that two of the crew developed beri-beri on the voyage, and were landed at one of the Cape Verde Islands. Another case of sickness developed later and was removed to hospital in Belfast, but considerable reticence is maintained concerning it.

SCOTLAND.

OPENING OF THE NEW BANGOUR VILLAGE ASYLUM.

This Asylum, which has been erected by the Edinburgh Lunacy Board at a cost of nearly £300,000, was formally opened by Lord Rosebery on October 3rd. During the eight years it has been in process of formation the asylum has received a great deal of criticism chiefly with respect to cost of construction. When, in 1897, the city of Edinburgh was formed into a lunacy district, it had to face the problem of accommodating nearly 1,000 lunatics who had hitherto been maintained in various asylums, particularly Morningside. Chiefly on the recommendation of the late Sir John Sibbald, the District Board resolved to adopt the village system for their new asylum, and, having purchased the Bangour estate of 900 acres, they invited competitive plans, of which those of Mr. Hippolyte Blanc, R.S.A., were ultimately adopted. In the village system the institution is composed of a series of detached buildings distributed over the ground without formality, everything suggestive of restraint being avoided. After the plans had been adopted they were severely criticised on the ground that they involved an unduly lavish expenditure on ornamentation, and finally the architect had to strip his elevations of practically all decorative adornment, and to rely for architectural effect on variations in the form of the buildings and variety in the external treatment of roofs and walls. Much thought has been expended on ensuring that the ordinary fittings of the houses are so constructed that the patients cannot employ them to do themselves harm. The windows, for instance, are opened and closed by a hidden mechanism, out of reach of the inmates. The main divisions of the village are the medical section at the east end of the estate, and the industrial section, at the west. Placed centrally are the laundry, kitchen, stores, bakery, engines, electric plant, and wood and iron workshops. In the medical section there is an administrative block, with admission wards in which the patients are kept for some days on entering the asylum before being finally allotted to some particular department. In this section, too, are a hospital for bedridden patients, and buildings for acute cases, as well as a nurses' home. In the western section are the industrial homes, with a recreation hall; these are at present designed for 750 patients, while the administration is on such a scale that the full number of 1,000 can readily be catered for when necessary. At the extreme west of the estate there is a farm with a completely-equipped steading, worked by the male patients. The village asylum is thus quite self-contained, having its own reservoir and water supply, a complete system of drainage in duplicate with terminal septic tanks, an electric light and telephone installation, fire hydrants, and a branch line of railway of its own. At present there are about 400 patients at Bangour, and they are coming on at the rate of about thirty a week from the other institutions in which they have hithero been boarded.

Lord Rosebery was received at the entrance to the administrative block by Bailie Richard Clark, the chairman of the board, and having formally opened the building, made a tour of inspection, accompanied by the medical superintendent, matron, and other officials. After the ceremony the company gathered for luncheon, and the toast of the Bangour village was proposed by Lord Rosebery. His lordship in no way belied the reputation he deservedly possesses as a graceful orator, yet many who heard him would fain have noted a

less pessimistic vein in his words. There was little prospect, he said, that his wish to see Bangour village more deserted than Goldsmith's hamlet would ever be consummated in the face of lunacy statistics of the past half century, which showed an increase of certifiable lunatics amounting to 231 per cent., while the general population had increased only at the rate of 75 per cent. In Ireland the contrast is even greater, because while there is an enormous emigration of able-bodied people from Ireland, there is an increase at the same time of lunacy, which seems to point to the fact so poignant to us that the best men are leaving the country, and only a large percentage of the weaklings, the helpless, and the insane remain behind. Again, speaking of the expenditure on lunacy, he found that the capital invested in asylums in the United Kingdom amounted to 24½ millions, and the annual expenditure on lunatics to 3½ millions. This money is paid by the nation, not for those from whom it can have any hope in the future, but for those who represent sheer waste and sheer decay. It is for this we build these sepulchres of living humanity, these tombs of the intellectually dead. As to a suggested remedy, it is no use thinking of suppressing marriage among these hereditarily tainted, nor had he much hope from the checking of alcoholism. He believed we could only do much by teaching a higher and better system of life, by showing people that their homes are better worth cultivating and inhabiting than any stray place they may care to visit; thus would there be a great reduction of the strain on the nerves which must inevitably be a cause of insanity. It is to be feared that Lord Rosebery has somewhat overlooked the aspect of an asylum which is most prominent to the medical mind—that it is primarily a place of cure. In his judgment the modern asylum seems solely to be a place of detention—humane and bereft so far as may be of the fetters and barred doors of the prison—but a prison none the less, a "sepulchre of humanity, a tomb." This conception doubtless it was which led him in the opening passage of his speech to express the hope that if any new asylum for the treatment of incipient insanity were proposed it would be carried out on a limited tentative scale, so as not to add to the enormous lunacy expenditure which presses on the country. Lord Rosebery's speech evoked a protest from Dr. Clouston in the form of a letter to the *Scotsman* a day or two later, in which the curative side of the modern asylum was emphasised.

LETTERS TO THE EDITOR.

THE AWAKENING OF THE GENERAL PRACTITIONER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If the general practitioner is to find professional salvation, he must find it for himself; and it is certain that he can if he will. It is possible that if he rouse himself he may get help from the minority in the profession who at present show almost complete indifference to his condition. It is possible that the successful consultants and specialists, and the men who are engaged in purely scientific work, and also those holding appointments, civil and military, under Government, may join hands with those who start a movement to promote medical law reform; but the movement evidently can be vigorously started and carried on by those only whose interests are most involved. Medical practitioners are the most highly educated and the best equipped for their work among professions. The State exacts this high standard, and in return confers no privilege whatever. In restricting its public appointments to qualified men, it merely safeguards its own interests. It can be demonstrated that protection of the profession by preventing practice by unqualified fraudulent pretenders would confer vastly greater benefits upon the people than upon medical men, and it can be as easily shown that a like effect would be produced by putting a check upon the traffic in quack medicines. The question is, How can the case be properly proved? Hardly, I think, by any other means than that suggested in your columns, namely, a Royal Commission. The lay press, including journals ostensibly devoted to exposure of humbug and fraud, are, as you have shown, against us. They are biassed by the fact that at least a million sterling is annually disbursed among them for quack advertisements. The British Medical Association, with its 20,000 members, forms, as I have before pointed out, merely a co-operative society for the publication of a cheap medical paper. It has done nothing, and seems indisposed to do anything, to improve the lot of the bulk of its subscribers. If these—the general practitioners—unanimously made the demand, it is possible that the forces and resources of the Association might be diverted into the desired direction. Nothing can be done there or elsewhere until the practitioners have united and prepared to make their voices heard with no uncertain sound. THE MEDICAL PRESS AND CIRCULAR is giving them the opportunity to do these things. Let us hope they will avail themselves of it.

I am, Sir, yours truly,

AN AWAKENED "G.P."

October 4th, 1906. Croydon.

THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Clement Sers repeats statements, but does not carry this question much further. He mistakes the British Isles for the British Empire, in which there is room for our surplus population for the next five hundred years. The whole empire contains at present only 55,000,000 of people of European blood. Germany has 62,000,000 in the Fatherland alone. She or some other equally virile race will have our oversea possessions in time if we do not people them ourselves. A few decades of the present decline in the birth-rate will place us in the position of France. Mr. Clement Sers would do well to read what leading French writers think of the position of their race—physically, morally, and materially—and of the causation of the decadence. If we are to be saved from a similar fate, the conscience of the people will need speedily rousing. By the term "well bred," I of course implied the scientific, not the social meaning of the term We can by known methods ensure the good breeding of the great bulk of our increase, and by proper organisation find place for them among their kith and kin beyond the seas, if there be not enough room for them at home.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

October 4th, 1906.

THE GENERAL MEDICAL COUNCIL ELECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The time is rapidly approaching when the registered practitioners of England and Wales will again be called upon to exercise the privileges of electing three of their number to represent them in the General Medical Council. I shall esteem it a favour if you will permit me to state through your columns that it is my intention to again offer myself as a candidate for re-election. During the ten years I have had the honour of a seat in the Council Chamber as a Direct Representative I have done my utmost to promote the cause of medical reform, and to advance the best interests of the profession as a whole. I am led to believe that I have discharged the duties to the satisfaction of the profession generally from the fact that in addition to receiving during the last few months numerous renewed promises of support from medical men in all parts of the country, I have received official intimation that resolutions in favour of my candidature have been passed by the following among other important organisations, namely: the Society of Members of the Royal College of Surgeons of England, the Association of Physicians and Surgeons of the Society of Apothecaries of London, the Midland General Practitioners' Union, and the Incorporated Medical Practitioners' Association. In conclusion, permit me to express my best thanks to those who have assisted me by their

support at former elections, and to say that if re-elected, I shall, as hitherto, endeavour to improve the conditions of medical practice, and to uphold the honour and dignity of the profession, giving special attention to furthering the interests of those engaged in general practice. Thanking you for your courtesy in permitting me to address your readers through your valuable columns,

I remain, Sir, yours truly,

GEORGE BROWN.

Mount Lodge, Callington, Cornwall,
October 6th, 1906.

MOTOR-CARS AND DUST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with considerable interest the correspondence on this subject; interest I mean of a personal kind, as early in the present year I contemplated joining the throng, by giving up my carriage and starting a motor-car. Your correspondent, Dr. Gilchrist, who strongly champions the modern method of locomotion, admits that the dust evil can scarcely be exaggerated, but he adduces as a strong point in favour of the motor-car, "its rapid adoption as a substitute for the omnibus drawn by horses in the streets of London will, it is hoped, discourage the development of the tramway." If your correspondent lived in London instead of at Nice, I fancy he would hold a very different view on this subject. We in London, and doubtless the same view is held in other large cities, consider the motor omnibus as one of the greatest curses of modern civilisation. Its stench, its deafening rattle, and its constant liability to a breakdown—apart from the terrible death-roll with which it has been ushered in—have rendered our main thoroughfares well-nigh intolerable. To quote from one of our highest-class newspapers of Wednesday last:—"It is no good beating about the bush—the motor-bus is a monstrous plague. Life is a torture on any of the main 'bus routes. The noise, the smell, the ugliness, the danger to life and limb—these are reducing many a noble thoroughfare to an Inferno."

Then to remedy the dust evil which motor-cars have created, Dr. Gilchrist suggests the making of special highways, or the widening of existing ones to accommodate followers of the new craze. Thus the already overburdened ratepayers are asked to pull down houses and make new thoroughfares for the few who have suddenly discovered that they cannot travel fast enough in horsed vehicles, regardless of the cost entailed thereby on the public and the ruin of property *en route*. I can only congratulate myself that I did not give way to my first impulse; my horse is still fast enough to take me to my patients' houses, and I have it not on my conscience that the public are being made to pay for my gratification.

I am, Sir, yours truly,

A LONDON PHYSICIAN.

OBITUARY.

THE RIGHT REV. MONSIGNOR MOLLOY, VICE-CHANCELLOR OF THE ROYAL UNIVERSITY OF IRELAND.

ALTHOUGH the late Rector of the Catholic University of Ireland was not a member of the medical profession, his connection with the knowledge of sciences closely allied to medicine were such that we feel we cannot allow his unexpected death to pass unnoticed. As our readers know, Monsignor Molloy passed away whilst staying at Aberdeen, on the occasion of the recent University celebrations. His life was a many-sided one, as, in addition to his theological work, he was deeply interested in science, and was well known to the Dublin public by virtue of the many and lucid lectures which he has delivered from time to time on scientific subjects Indeed, his grasp of the latter was such that he was able to make the most abstruse of them clear to a non-scientific audience. In 1874, Monsignor Molloy was appointed Professor of Natural Philosophy to the Catholic University, and this position he held until 1887. In 1882 he became Rector of the Catholic University. He was a member of the Council of the Royal Dublin Society, and in the lecture rooms of that famous body he delivered many of his lectures. In 1903 he was appointed Vice-Chancellor of the Royal University of Ireland, and at the time of his death he was representing that institution at the Aberdeen celebrations. Monsignor Molloy enjoyed a wide popularity both for his scientific attainments and also for his social gifts, not only amongst those who belonged to the same school and religion, but amongst those who differed widely from him. In the latter connection his loss will be deeply felt throughout the entire of Ireland, for he constituted a link between men of different views at a time when other men in similar positions are striving to create discord. Whether anyone can be found capable of taking his place time will show. Should he be found, there is a wide field for his labours, and never was he more urgently required.

WILLIAM CRAWFORD PALMER, L.R.C.P.&S.Ir., L.M.

WE regret to announce the death of Mr. W. C. Palmer, who died suddenly at Birkenhead on September 28th, where he was taking charge of the workhouse infirmary. According to evidence given by Nurse Amy Braithwaite, the deceased on Friday morning went to the surgery at the workhouse hospital. He appeared in good health, and it was while he was writing out a prescription that witness heard him exclaim, "Oh, sister!" He fell back in his chair and became unconscious. Dr. Stansfield arrived at the institution shortly afterwards, but found that Mr. Palmer was then dead. In his opinion the contributory cause was angina pectoris.

SPECIAL ARTICLE.

THE LONDON MEDICAL EXHIBITION.

The London Medical Exhibition, held last week at the Royal Horticultural Hall, Westminster, was a great triumph for our enterprising contemporary, the "British and Colonial Druggist." The exhibition was only the second that that journal has organised, but in variety and interest of exhibits, in excellence of organisation, and in amount of patronage secured it is difficult to conceive of anything more successful. Indeed, medical men generally—or, rather, those who paid a visit to the Exhibition—are under a debt of gratitude to the organisers for their care and foresight, and for giving them the opportunity of seeing many things which they had heard or read of, but never seen. We only hope that they suffered no financial loss, for their hospitality and courtesy deserved more than a mere *succès d'estime*. Every arrangement that could be made for the comfort and convenience of visitors had been carefully thought out and arranged, and we fancy that Mr. Norman Flach, the secretary, to whom "complaints" had to be made, must, whatever his other duties entailed, have had an easy time on that score. The spacious Horticultural Hall was got up in attractive style, and excellent orchestras played with scarcely an interval during the whole time—11 a.m. to 6 p.m.—the exhibition was open each day. There were cloak-rooms provided for both sexes, a reception-room where visitors were kindly entertained by the "British and Colonial Druggist" staff, and capital refreshment rooms. If there were a criticism to offer, it would be that six o'clock was rather early for the closing time, as many practitioners who were busy in the daytime would have been glad to go in the evening. At any rate, a large and satisfactory audience was secured, and no one who went, we are sure, considered the time ill-spent. As to the

exhibitors themselves, they equally must have been satisfied with the opportunity afforded them of introducing their goods to the notice of so large a number of practitioners.

To give a detailed account of the wealth of exhibits would carry us far beyond the limits of our space, and we can here but note some of the inventions and products that struck us particularly; but when we have said all we have to say, we shall be constrained to say with the Queen of Sheba, "the half hath not been told." A hundred and two firms had taken stands, to say nothing of those who sent photographs and plans of sanatoria, nursing-homes, and so on, so that to have got a complete knowledge of all that was on view would have entailed a visit every day for the seven hours the exhibition was open.

Opposite the main entrance was Armour's, a firm who have safely weathered the storm of abuse that swept over Chicago and all its packing firms. The Americans are nothing if not hysterical, and the British, thanks to the American methods of journalism that have established themselves over here, are apt to follow the Transatlantic lead. Now, however, that people are coming to their senses, they are beginning to find out slowly that the "Jungle" exposures were in a measure the result of a carefully laid campaign by a journalist in search of copy. That the Chicago packing-yards were above reproach cannot be maintained in these days, when people demand, and rightly demand, a high standard of hygienic excellence in the preparation of their foods; but at any rate, Armour's medical products are prepared in special workshops, under "laboratory" conditions, and no sort of reflected odium could attach to them. Their newest preparations, the "Elixir of Enzymes," a fluid containing the active principles of all the digestive ferments, and "Eucapron Solution," a preparation containing Beta-eucaine Lactal and Suprarenalin, are very attractive. The advantage possessed by the latter that it can be sterilised by boiling without damage renders it a useful addition to local anæsthetic solutions. Southall Bros. and Barclay, Ltd., had many improvements in sanitary towels to show, foremost amongst which must be mentioned their compressed towels. These are ordinary towels subjected to such pressure that they are reduced to the size of about a large pill-box, and this advantage in all probability will commend itself to all women. Their accouchement sets, infants' "Knapkinettes," and dressings of all kinds exhibit the elegance which have made them famous; and special mention must be made of an ideal india-rubber hot-water bottle, the "Celerio," which gives no trouble in filling, and cannot leak. One of the smartest things that Messrs. Southall had on show was "Lofatol," an aërated cod-liver oil in syphon. The oil being charged with carbonic acid has a consistence which ordinary cod-liver oil cannot attain, and the "sting" produced in the mouth by the bubbles of gas disguises to a great extent the ordinary objectionable taste of this valuable drug. The "Idris" Company were showing a number of their well-known waters, and we learned for the first time that they can supply an artificial Vichy water in syphons. Moreover, they can supply a new radio-active water, "Igmandi," which is likely to be much sought after. A particular feature of their syphon is the spout, which is cleverly designed so that by no possibility can the contents of the bottle come into contact with the metal. "Perrier" was on view and on draught, and medical men who have not tasted this water will be glad to find how pleasant and refreshing it is. Mr. Zeal had a stall for his thermometers, and his two chief varieties, the Aseptic Clinical and Repello, are as useful as they are ingenious. The former can be kept always aseptic, as the thermometer itself is carried in a glass tube, which can be filled with antiseptic fluid, and the Repello, which is set without shaking, is a thing of beauty.

The Aylesbury Dairy Company had on show an infant food, "Pollyta," which they have recently brought out, and for which they claim a specially high percentage of fat; and besides these were specimens of their Humanised Milk, Humanoid, Peptonised Milk, Sterilised Milk and Cream, and Whey, all obtainable in bottles. Everybody knows, or should know, Messrs. Zimmerman's products—Chotropine, Chloralamide, and Piperazine are household words. Sublamin is newer, and was on view. It is a non-toxic, non-corrosive sulphate of mercury, and, if it acts as powerfully as is claimed, should seriously challenge the supremacy of perchcloride of that metal as a routine antiseptic. Many new organic products also were shown, and their stand alone was a lesson in materia medica and pharmacy. The same may be said of Mr. W. Martindale's. First, there was the new 12th Edition of the Extra-Pharmacopœia, the breviary of the progressive practitioner, and side by side with it the elegant preparations which it explains. "Sterules" are highly convenient glass capsules containing just enough of a preparation for one dose, and glass and gelatine capsules of various kinds make drug-taking and drug-giving a luxury. "Rodagen" is an interesting preparation, being the dried milk of thyroidectomised goats, which may have a field of usefulness in hypertrophic conditions of the thyroid; whilst the Oleogen series promise to be of great value in prescribing inunctions. The Jeyes' Sanitary Compounds Co., Ltd., had their Cyllin products on view. It is almost superfluous to say anything about these, so much are they appreciated for their high bactericidal properties; but it may not be generally known that the company now make surgical dressings impregated with Cyllin, and put up a dusting-powder, an inhalant, and a syrup—the latter for internal use.

(*To be concluded.*)

REVIEWS OF BOOKS.

LUNACY REPORT FOR IRELAND. (*a*)

THE Inspectors begin this report by reference to a former document of the same nature. In 1894, the conclusions arrived at were that the apparent increase in the number of the insane was "mainly due to accumulation," and was partly owing to a mere transfer from the unregistered to the registered "as shown in the reduction in the number of lunatics and idiots at large," but that yet "the annual increase, in face of a shrinking population, of the number of First Admissions, including such a large proportion of First Attacks of insanity, almost irresistibly pointed to some increase of occurring insanity in particular districts."

We do not know that the conclusions of the present report, to be presently referred to, are much more definite, but we learn enough from them to be pretty confident that the sensational statements so often made are exaggerated and that there is really no great cause for alarm.

There is, of course, no question that the number of registered insane has increased greatly of late years—from 9,980 in 1851 to 25,050 in 1901.

With regard to the special proportionate increase which is supposed to have occurred in Ireland in comparison with other countries, the Inspectors point out that this is, at least in part, a necessary consequence of emigration, "as it is clear that, although emigration reduces the general population, it does not reduce the number of the insane, as the number of those who leave the country when actually insane may be regarded as negligible."

That mere redistribution of the population may have much to do with the apparent increase is shown by a fact stated early and prominently in the report before us: "The return of the insane in Ireland, according to the last census, shows a diminution under all heads except in the numbers located in asylums." That the transfer of patients from one class to another does not indicate a change in the incidence of insanity is true, but persons sent to asylums are carefully registered and live longer than when wandering with-

(*a*) "Supplement to the fifty-fourth Report of the Inspectors of Lunatics in Ireland, being a Special Report on the Alleged Increase of Insanity."

out care or subject to the organised neglect of a workhouse. Besides, an increased number of admissions to asylum probably connotes not merely a transfer from one class to another of the registered insane, but the introduction into the register of a great number of persons whose insanity was previously altogether unregistered.

A very remarkable fact is pointed out by the Inspectors with reference to the age classification of the total insane: "The population under twenty years of age has very largely decreased during the thirty years from 1871 to 1901," while "the insane under that age have decreased at almost as great a rate." "The population between the ages of 20 and 55 showed decrease, while the insane of a similar age period increased by 64 per cent.; and the population over 55 also decreased, while the insane of that period showed an increase amounting to 185 per cent." These deductions are made from returns obtained from the Registrar-General, and it is very curious that they are supported by certain figures arrived at in quite a different way by one of the asylum physicians, whose reports are appended to that of the Inspector's. That gentleman has pointed out that in his district the proportion of persons admitted to the district asylum between the ages of 15 and 30 has not increased, but rather diminished (from 32.6 per cent. of the total admissions in 1886 to 28.1 per cent. in 1902). In a similar period the proportion of admissions over 50 years had risen from 15.2 to 23.6 per cent. The observations, of course, are not of identical value, but they tend to corroborate each other. We may gather that the "hereditary insanity of adolescence" (Clouston), the solid nucleus of that wonderful nebula "dementia præcox" (Kräpelin), which most modern authorities regard as the most hereditary and the most constitutional form of insanity, is not that which is increasing in Ireland. If the generally accepted views are correct there is hope in this fact, as it seems to show that the question is not one of race degeneration.

It is pointed out that, imperfect as asylum statistics must necessarily be, the best attainable criterion as to increase of insanity is the number of freshly occurring cases, and that this is best ascertained from the first admissions to asylums that have been not more than twelve months ill, when admitted. The proportion of cases of first attack not existing more than a year on admission to the total of admissions has not varied much in the decade which the Inspectors specially review, but their proportion to the population shows an increase from 3.94 per 10,000 of the population in 1894 to 5.07 per 10,000 in 1903. "It must be borne in mind, however, that there is nothing to show that the cases of first attack were taken from the young and vigorous members of the community. As we have shown elsewhere, a large proportion of them were cases of dotage or senile decay, who had never previously been insane." We venture to think indeed, that there is much to indicate that this is the principal explanation of the apparent increase in this instance. Everywhere, and notably in London County, there is the same complaint, that of late years a great proportion of the cases admitted are senile dements—of course, incurable, but often enough intractable, and almost always requiring a great deal of care. The cause for the increased admission of this class of late years is obscure. The greater longevity of the population contributes, and probably also changes in the habits of the people, who find it harder to manage a doting relative in their homes. Decreasing toleration of the insane and feeble, diminishing sense of responsibility for those whom the State is supposed to care for, together, perhaps, with greater confidence in asylums, may be further contributory agencies.

The increased longevity of asylum patients accounts for a considerable accumulation in those institutions. The death-rate in the Irish asylums has been steadily falling for many years. In 1883, it was 9.4 per cent. on the daily average number resident, while in 1903 it had fallen to 7.8 per cent. It is noted that in one of the largest asylums the death-rate has fallen by one-half within the last twenty years. The Irish death-rate is considerably lower than the English (10.4 per cent. for the whole of the County and Borough Asylums in the year 1903). This is no doubt chiefly due, as the Inspectors pointed out, to the greater mortality in the latter country from general paralysis (some five or six times greater than in Ireland).

Contrary to what the *a priori* reasoner would expect, the Irish Inspectors find, like their Scotch colleagues, that the proportion of the insane to the population is greatest in the most remote rural districts and least in the large centres of population.

On the causation of insanity the Inspectors wisely abstain from dogmatising. We have not noticed anything about the marriage of near kin (probably less prevalent in Ireland than anywhere else in the world) which we used to hear about, and we are glad to find that what we have always supposed to be a private "fad" of Mr. John Morley's, namely, that the curative operation of asylums increases the hereditary predisposition to insanity of the general population, has been given the go-by. There never seems to have been a shred of evidence to support this purely doctrinaire notion.

The influence of emigration has received much attention. The sane go; the insane remain. Emigration is to England or America; the homing instinct of the Irish often brings the yearning invalid back to his native land, where the process of decay, perhaps started abroad, develops into complete ruin.

The Inspectors draw attention to the number of the Irish who become insane in America, as shown by the statistics of American asylums. It is out of fashion to assign "moral" causes for mental disease. We venture to think, nevertheless, that such conditions as nostalgia are very genuine and are probably not of bacterial origin. We are of opinion that the simple peasant from a hillside in Mayo or Galway, a man with the narrowest outlook of any man in Europe, perhaps, is apt to lose his moral bearings when thrown into the whirl of life in an English or American manufacturing town, and that this happens far less from racial peculiarities than from educational and environmental surroundings.

In summing up, the Inspectors tell us virtually that it is impossible to state positively whether an increase of occurring insanity has taken place; that a numerical increase among the registered insane which has undoubtedly taken place is mainly among the rate-supported insane; that the increase of asylum patients is due to accumulation; to absorption of the unregistered insane; to a widening in the application of the term insane; to greater public confidence in asylums; to an increase and greater accessibility of asylums; to greater longevity both of the general population and also of the asylum population; to the return of broken-down emigrants; and, finally, "to the fact that the Celtic race, notwithstanding their undoubted intellectual gifts, are peculiarly prone to mental disease." This last conclusion the Inspectors offer with some suggestion of doubt. We are inclined to think it is very far from definitely proven.

A New Journal.

"L. G. O." is the name of a new journal, if one may apply that description to the incorporated descendant of two previously existing publications. The two parties to this coalition were the "Local Government Officer" and our old and valued friend the "Public Health Engineer." "L. G. O." appears with the announcement that it is the official organ of the local government officers. We wish it a long lease of life, and feel that we may do so with entire confidence, knowing the past traditions of thoroughness and business-like enterprise that governed the "Public Health Engineer." With the other party to the embodiment we are not so well acquainted, but its reputation is excellent. The copies of the new journal with which we have been favoured are excellent in form and substance.

MEDICAL NEWS IN BRIEF.

Bath's Prosperity.

While in so many cities and towns throughout the country to-day residents are lamenting the increase of local rates, it is a remarkable fact that in a city possessing the residential advantages of Bath, the Municipality have been able to make a reduction in the rates of the city to the extent of 6d. in the £. Thus for the current year the demand will only be 5s. 10d. in the £ as compared with 6s. 4d. for the year ended March, 1906. This gratifying intelligence for the residents of Bath was announced at a meeting of the Town Council held on Tuesday, and will no doubt cause envious eyes to be turned in the direction of Bath as a place of residence. Important factors in this large decrease of local taxation have been the increasing value of Corporate property in recent years (an increase which will naturally continue as old leases fall in), and the prosperity of the famous bathing establishments, which are attracting visitors in increasing numbers annually. One great advantage which Bath possesses over the other principal resorts for the water "cure" is that its mild and equable winter climate has made it an all-the-year-round resort, and it may, therefore, be visited when many of the continental resorts are closed. Those of the travelled community who have visited the stately city of Bath will know that there are few more charming spots in Europe, and the knowledge that its civic finance shows so healthy a state should do much to further increase its popularity as a residential centre.

Research at Khartum.—The Wellcome Laboratories.

THE second report of the Wellcome Research Laboratories at Khartum has just been issued in a handsome quarto volume of 255 pages, enriched by several excellent plates, coloured and uncoloured, in addition to numerous photographs and maps. These laboratories were established three years ago at the Gordon Memorial College, Khartum, by Mr. Henry S. Wellcome, as a free gift to the Sudan Government, and are intended, among other objects, to promote the study of tropical disorders, especially the infective diseases of both man and beast; to study the toxic agents employed by the natives; to carry out such chemical and bacteriological tests in connection with water, food stuffs, health, and sanitary matters as may be found desirable, and to undertake the testing and assaying of agricultural, mineral, and other substances of practical interest in the industrial development of the Sudan. The director, Dr. Andrew Balfour, has been so successful in his pioneer work that his staff has been strengthened by the addition of a chemist (Dr. William Beam) and a travelling pathologist and naturalist (Dr. Sheffield Neave). A valuable adjunct in the shape of a floating laboratory will likewise be placed at his disposal before long. He has enlisted, moreover, the sympathies of several officers, both medical and veterinary, employed by the Sudan Government, and is getting much assistance from them as collectors and inquirers. The "mosquito brigade" has been doing good work, not only in Khartum, but in the Anglo-Egyptian Sudan generally, and the report gives statistics on the subject. There are valuable papers on other biting insects besides the mosquito, including the deadly tsetse fly. There is one on vegetal pests by Mr. F. V. Theobald, and one by Dr. Balfour on trypanosomiasis in cattle and mules. An institution of this comprehensive character must needs prove of incalculable benefit to the country with which it is more immediately concerned, while it cannot fail to act as a useful auxiliary to home schools of tropical medicine.

Death Under Chloroform at North Shields.

MR. RUTHERFORD, deputy-coroner, last week held an inquest in the Town Hall Buildings, North Shields, concerning the death of Harris Hamilton, 42, donkeyman, in the Tynemouth Victoria Jubilee Infirmary. Harriet Hamilton, widow of the deceased, said that, on the 18th ult., her husband returned from South America. During the voyage he and several members of the crew were attacked with yellow fever, and he was still suffering from the effects when he came home. He was also bitten on the left hand by an insect while in the engine-room of his vessel, and after he returned home the wound became inflamed. He consulted Dr. Baker on Wednesday, and on the following day went to the Infirmary, where he died.—Dr. Baker stated that the deceased consulted him on Wednesday about a growth on the back of his left hand. It was a "warty" growth, the size of a florin, and might have been caused by the bite of an insect. The deceased and his wife were both anxious that something should be done, and witness told him to go to the Infirmary next morning to undergo an operation. Witness went to the Infirmary at 10.50 a.m. on Thursday, and administered chloroform to the deceased in the presence of a nurse. After he had done so, witness was joined by the house surgeon, who performed the operation of cutting away the growth. This lasted only a few moments, and it was practically finished when witness noticed that the man was breathing badly. The deceased was a strong, healthy-looking man. Before administering the anæsthetic witness took all the necessary precautions. After the patient's collapse artificial respiration was kept up for over two hours, and several other means of restoration were tried without avail. It was likely that the attack of yellow fever, of which witness had not been told previously, had weakened the man's system.—The jury found that the deceased met his death while undergoing an operation under chloroform, which was properly administered.

Medical Sickness and Accident Society.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held on the 28th ult. There were present Dr. de Havilland-Hall, in the chair; Dr. J. Prickett, Mr. William Morris (Birmingham), Dr. St. Clair B. Shadwell, Dr. M. G. Biggs, Mr. H. P. Symonds (Oxford), Dr. F. S. Palmer, Dr. J. Brindley James, Dr. J. W. Hunt, Mr. Edward Bartlett, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The records of the Society for the summer months is exceptionally good, and has already balanced the heavy disbursement for sick claims which, as usual, was experienced in the early spring. The number of new entrants is above the average, but less than in last year, when the record number of new members was obtained. The committee are pleased to find an increased proportion of dental surgeons among the new entrants. All the benefits of the business can be obtained by members of this branch of the profession, and it is hoped that their numbers in the Society will rapidly grow. Prospectuses and all further particulars on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C

Girl's Death under Chloroform.

At the Keighley Victoria Hospital, Leeds, last week, when a girl of 14 was about to be operated upon by Dr. Moffat for deformity of the legs, Mr. J. N. Dobie administered chloroform after finding that the patient's heart appeared to be sound. Twenty minutes later she suddenly expired. The case has been reported to the district coroner.

A Novel Inkstand.

We have an inkstand before us of which the director of the "Association for the Supply of Pure Vaccine Lymph" is the inventor. Let it be remarked that this gentleman assumes no connection between ink and vaccine, but as a practical man of business he has put on the market this "Sapphire" inkstand, which strikes us as an ingenious attempt to supply an inkpot in which the level of the ink never falls. This is attained by providing an acid-proof india-rubber reservoir of the very best quality which is sufficiently compressed as required by turning round the top of the inkstand. A little glass cup like a minim measure passes into the reservoir, and into this cup the pen is dipped. The Sapphire will help to ease the minds of writers with bad memories or forgetful servants.

North-East London Clinical Society.

The opening address of the Session will be delivered at the Tottenham Hospital to-morrow (Thursday), October 11th, at 4.30 p.m., by Sir John Halliday Croom, who will take as his subject "Exophthalmic Goitre in its Obstetrical and Gynæcological Aspects." All medical practitioners are cordially invited.

The Annual Dinner of the Society will be held on the same evening at 7 for 7.30, at the Great Eastern Hotel, Liverpool Street, when the President, Dr. Arthur Giles, will occupy the chair. Members of the Society are reminded that ladies are invited to the dinner, and that tickets, price 7s. 6d., exclusive of wine, can be obtained from the honorary secretaries, Dr. G. P. Chappel, Lansdowne House, Tottenham, and Mr. C. E. Hutt, 626, High Road, Tottenham, N.

Hop-Pickers and Small-pox.

At a meeting of the Alton Rural District Council last week, the medical officer reported that a hop-picker who had been living in the hoppers' barracks at Froyle had developed small-pox at Andover the day after he left Alton. The premises used by the pickers have been thoroughly disinfected, and the utmost precautions have been taken to prevent the spread. No further cases are suspected.

PASS LIST.

Royal College of Physicians and Royal College of Surgeons in Ireland.

Preliminary Examination.—Candidates have passed this Examination as undernoted.—U. L. Bourke, J. J. B. Breakey, D. Burns, C. H. Christal, H. Cochrane (with Honours), A. N. Cole, A. H. Crely, T. Dowser (with Honours), R. M. Erskine, F. C. Fisher, J. Fitzgerald, M. Golding, A. F. C. Hogg, C. W. Joynt, H. R. L'Estrange, F. J. Meenan, S. H. Moss, C. E. Murch, R. J. McArdle, P. H. McDough, A. J. Neilan, J. L. Nunn, H. V. Odlum, L. O'Donovan, R. H. Orr, K. L. O'Sullivan, J. C. Sproule, V. J. White, and W. Williams.

First Professional Examination.—H. E. Clarke, H. D. Gasteen, J. Germley, J. J. Glynn, J. D. Hamilton, E. E. Holden, R. H. Hodges, W. V. Johnston, A. P. Kennedy, A. M. A. Lanphier, L. A. Moran, W. H. Murray, H. McAdee, J. McMullen, T. B. Newman, M. A. O'Callaghan, B. O'Donnell, J. H. O'Neill, J. Purcell, A. Wiley.

The Royal University of Ireland.

The following candidates have passed the Third Examination in Medicine, Autumn, 1906:—

Upper Pass.—*David S. Clarke, B.A., *William Faith, James Ferguson, B.A., *Michael P. Fitzgerald. William P. MacArthur, John J. McGrath, Kenneth F. Mulligan, *John A. Sinton, Verner Wiley. Candidates whose names are marked thus (*) may present themselves for the further examination for Honours.

Pass.—Robert J. Clarke, Alexander W. Connolly, Hugh J. Grant, Patrick Keelan, Peter J. Keogh, Alan Kidd, John C. Macaulay, Samuel W. McComb, William C. McCullough, Robert A. McLaverty, Hamilton Mathewson, Ulick J. G. Mulligan, Patrick J. O'Brien, B.A., Michael O'Connell, David O'Sullivan, Michael Shipsey, Bruce A. West, John N. Williams.

University of Durham—Faculty of Medicine.

The following candidates have passed the first examination for the degree of Bachelor in Medicine:—

1.—*Elementary, Anatomy and Biology, Chemistry and Physics.*—Eva Lumb.

2. *Chemistry and Physics.*—Isaac Bainbridge, John Akilade Caulcrick, Helen Grace Clark, Robert Vickers Clayton, John Hare, John Parkinson Higham, Howard Tomlin Hunter, George Eric Warner Lacey, Samuel Littlewood, Eric Hemingway Shaw, Stanley Worthington, James Carruthers Young.

3. *Elementary Anatomy and Biology.*—Eliot Watson Balke, Elliot Jessie Ramsbotham, Madeline Rosa Shearburn, Olivia Nyna Walker.

The following candidates have passed the Third Examination for the Degree of Bachelor in Medicine:—*Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.*—Honours—Second Class.—Charles F. M. Saint, Elizabeth Patteson, David Ranken. *Pass List.*—Kenneth Bruce Allan, Herbert Ridley Crisp, Henry Glendinning Davison, Harold Ferens, Charles Westland Greene, Isaiah Hodgkinson, Frank Widowfield Melvin, Charlotte Purnell, Francis AidanRobinson, Edward Davison Smith, Basil Taylor, John Henry Tripe, M.R.C.S., L.R.C.P., Lionel Langford Westrope, Frank Whitby.

St. Mary's Hospital Medical School, Paddington.

The following awards have been made as the result of the Entrance Scholarship Examinations held on September 24th, 25th, and 26th:—

Open Scholarships in Natural Science.—£145 and £78 15s. G. Roche Lynch, St. Paul's School, and R. G. Sparkes, Felsted School, equal. The sum of the two scholarships equally divided. £52 10s., A. Murray Stuart, Cheltenham College; £52 10s., P. Withers Green, Epsom College.

University Scholarships.—60 guineas, W. D. Hopkins, B.A., Trinity Hall, Cambridge; 60 guineas, F. G. Caley, B.A., Pembroke College, Cambridge, G. H. Drew, B.A., Christ's College, Cambridge, equal.

The *Epsom College Scholarship* (value £145) has been awarded to T. W. W. Powell, a student of the College, on the nomination of the Headmaster.

Charing Cross Hospital Medical School.

The following Entrance Scholarships have been awarded:—The Epsom Scholarship (115 guineas), to Mr. B. F. Eminson. The Livingstone Scholarship (100 guineas) to Mr. N. C. Lake. The Huxley Scholarship (55 guineas) to Mr. H. Smith. Entrance Scholarships have also been awarded to Mr. R. F. Eminson (60 guineas) to Mr. A. E. Huxtable (40 guineas), to Mr. M. Barker (30 guineas). Universities Exhibitions of 36 guineas each have been awarded to Mr. F. C. Davies, Cambridge University, and Mr. E. A. Ramsden, Oxford University.

Guy's Hospital Medical School.

The following Entrance Scholarships and Certificates have been awarded:—

Senior Science Scholarship for University Students.—£50, A. H. Crook, B.A., Christ's College, Cambridge. Certificate, C. C. Holman, B.A., Caius College, Cambridge.

Junior Science Scholarships.—£150, F. Cook, Preliminary Scientific (M.B.) Class, Guy's Hospital. £60, E. G. Schlesinger, Scientific (M.B.) Class, Guy's Hospital. Certificate, G. T. Smith, Alleyn's School, Dulwich.

Entrance Scholarships in Arts.—£100, W. A. Young, Colfe Grammar School, Lewisham. £50, H. Webb Rossall School. Certificate, N. E. Farr, St. Paul's School.

Entrance Scholarship in Dental Mechanics.—Mr E. A. Tomes.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Post-Typhoid Periostitis and the Typhoid Spine.—Wilson (*The Med. Chronicle*, August, 1906) discusses these two conditions and the relations between them. Post-typhoid periostitis occurs in about 1 per cent. of typhoid cases, but in comparison with the other acute specific fevers the complication is common. The typhoid spine is much less common, and only some forty cases have yet been described. The condition appears to be more common in men than in women. The onset is usually gradual, the patient complaining of weakness and pain in the back when first allowed to sit up after his fever. In some cases the pain does not set in till several weeks or months after the fever. In nearly all the cases the preliminary aching has been followed by very severe pain, which may continue for as long as four months. Remissions and exacerbations are common, and the recovery is slow and gradual, some pain and weakness persisting for a year or more. In about half the recorded cases there was an irregular pyrexia, the temperature ranging between 100° and 103° F. All the recorded cases with one possible exception recovered. Some spinal deformity resulted in eleven of the cases. Gibney, who first described the condition, considers that it was the result of an inflammation of the periosteum and of the fibrous structures binding the spinal segments together. This explanation has been generally adopted by other writers, but some, including Osler, describe the condition as a neurosis similar to that known as "irritable spine." The great difficulty in the way of accepting a periostitis as the explanation is that in no case has there been any sign of suppuration, though suppuration is the usual result of post-typhoid periostitis in other parts of the body. Those who would explain the condition as a neurosis attribute the spinal deformity that sometimes occurs as due to an associated tuberculous lesion. The presence of a very pronounced Widal's reaction with the blood during the attack suggests strongly that the organism was the typhoid and not the tubercle bacillus. K.

Massive Doses of the Salicylates in Rheumatic Fever—Clarke (*American Journ. Med. Scien.*, September, 1906) deals with the value of large doses of salicylate of sodium in the diagnosis and treatment of acute rheumatic fever. The tendency of late years at the Lakeside Hospital has been to increase the dose, and the seventy-four cases treated during the last six years are analysed with a view of estimating the value of this treatment. An administration of 240 grains or more in the 24 hours is considered a large dose. The routine treatment is to give the drug in doses of from 15 to 20 grains every hour while the patient is awake until toxic symptoms are evident. When the first sign of toxic symptoms is evident the administration is stopped; when these symptoms have disappeared the drug is given every two hours. The effect on the fever is very marked, and a composite chart of the seventy-four cases shows that in 36 hours the temperature became normal, and did not afterwards rise above 99° F. As a rule, the pain and swelling are completely gone by the fourth day, and in only four patients did any joint become involved after the treatment was begun. In only 13 per cent. of the cases was there any endocardial complication, and in one case pericarditis. There was one fatal case, a patient who took 580 grains at the rate of 20 grains an hour before any toxic symptoms developed; for two days he did well, then suddenly became wildly delirious, and died on the tenth day. The *post-mortem* examination showed œdema of the brain, and vegetative endocarditis. It is doubtful whether death was due to salicylic poisoning or to rheumatic meningitis. It was found that on an average the true rheumatic patient could tolerate from 150 to 300 grains of the drug before showing any toxic symptoms, while persons suffering from other forms of arthritis became toxic on much smaller doses, the gonococcic cases, for instance, averaging 131 grains. Further, any patient having fever and pain after 48 hours' treatment is looked on as a doubtful rheumatic, and careful search instituted for the underlying cause of the arthritis. K.

Digestion in Pancreatic and Gall-Bladder Disease—Buysch has investigated (*Zeitschr. für Klin. Med.*, Bd. 58, S. 518) the digestive and absorptive processes in a series of patients who were suffering from pancreatic diseases. He finds that, when the outflow of pancreatic juice is more or less diminished, the fat absorption is most interfered with, and that from 50 to 60 per cent. of the ingested fat apears in the fæces. On the other hand, the splitting of the fat molecule into free fatty acid and glycerine is not inhibited, and considerable quantities of soap are found in the bowel. The loss of proteid in the fæces averages 20 per cent. When, in addition to the absence of pancreatic juice, the bile is also cut off from the intestine, from 80 to 90 per cent. of the fat is lost, and about 33 per cent. of the proteid. The carbo-hydrate is under both circumstances well absorbed. Intestinal catarrh and increased peristalsis have the same effect as pancreatic disease in increasing the amount of material lost in the excreta. While in icterus alone the dried fæces can contain up to 80 per cent. of fat, in pancreatic disease not more than 60 per cent. is present. This is explained by the fact that in the latter case proteids also figure largely in the fæces, and shows that one can draw no definite conclusions concerning fat absorption from mere percentage analyses. In all cases, in fact, the total quantities excreted, as compared with the total quantities ingested, must be determined. Buysch has also shown that emulsified fat is no better absorbed than ordinary fat in pancreatic disease, and he has proved that in cases of diabetic acidosis the diminished alkalinity of the intestinal secretions may lead to a diminution in the digestion and absorption of fat. In such cases as these last mentioned one cannot, therefore, from the presence of much fat in the fæces diagnose the existence of pancreatic trouble. M.

Cardiac Massage.—Investigations carried out on the hearts of men who had just died has shown (*Wiener Klin. Rundschau*, 1905, No. 50-52) that that organ retains its power of contraction under the influence of certain stimuli for about an hour after somatic death. Among the stimuli employed is the procedure advocated by v. Prus—*i.e.*, resection of a couple of ribs, opening the pericardium, and rhythmical compression of the heart by the hand. Whilst in men, in whom this procedure had been carried out for the relief of chloroform syncope, no revival took place, the contrary was found in animals, which could be easily revived after deep choloroform narcosis. The difference, according to Müller, the author of the paper, lies in the fact that in the animals the heart is sound, while in men who die under chloroform the heart is always diseased. Along with massage, one may endeavour to bring about a direct flow through the heart. This is done by introducing a canula into a large vein in the arm, and transfusing under high pressure warm saline solution. Along with this the direct manual compression should be practised, but it is enough to introduce two figures into the pericardial sac for that purpose. The author thinks that the procedure is worth trying, not only in chloroform narcosis, but also in death from coal-gas and the like, provided that

no post-mortem rigidity has made its appearance. The injections especially act as powerful cardiac stimulants, and should be repeated if necessary. The paper is based on experiments on five animals, four of which were revived by the method described. M.

Typhoid Nodular Colitis.—Whipple gives a detailed account (*Johns Hopkins Hosp. Bulletin*, August, 1906) of the pathological findings in the colon of a case of colo-typhoid. The patient was a man aged 37, who was admitted to hospital for cardiac failure, and who died there without presenting any signs pointing to abdominal trouble. At the post-mortem, mitral stenosis and associated passive congestion of the liver and other organs were found, but, in addition, typhoid lesions were found in the large intestine. The stomach and small intestine were normal, and there was not the slightest swelling of the agminated or solitary follicles. The mucous surface of the cæcum and colon was thickly covered over with small sessile nodules from 2-10 m.m. in diameter, and which projected about 4 m.m. from the surface. The larger nodules were ulcerated on the surface, the ulcers being clean-cut and in places extending down as far as the muscularis mucosæ. The rectum showed intense congestion, but no nodules. Microscopically it was found that the solitary follicles of both large and small intestine were perfectly normal, and even those that were within or in the neighbourhood of the nodules were hardly altered. The nodules themselves were made up of an œdematous stroma, the predominating cells being large, oval, epithelioid cells with eccentric nuclei and few granules. Some lymphoid and neutrophile cells were also present, and there were small scattered areas of necrosis. The writer lays great stress on the distinction between these structures and hyperplastic lymphoid follicles, and maintains that the term nodular enteritis should be limited to the former condition. Actual lymphatic hyperplasia is chiefly found in children dying from acute infections, and the nodules found in such cases are much more evenly distributed over the colon. It is also pointed out that typhoid intestinal lesions limited to the colon are very rare, this being the first case encountered out of 217 autopsies in typhoid patients. Very few cases also are reported in the literature, and only three undoubted examples could be discovered. On the other hand, some involvement of the colon, along with the iliac lesions is usually met with. M.

Auto-Prognosis.—Landolfi (*Gaset. d'Ospedali*, Milan, 1906) is convinced of the great value of Gilbert's method of auto-sero-diagnosis, which consists in reinjecting, subcutaneously, serum or effusion taken from the patient's own pleura or peritoneum. A febrile reaction follows when there is tuberculous infection, but not if no tuberculosis is present. Landolfi has been studying the reaction obtained, and he states that it is able to afford important information, not only as to the tuberculous nature of the lesion, but also as to its seriousness and the ultimate outcome. For these points the particulars of the reaction must be recorded for several days after the injection, the curve then showing details which differentiate the affection and announce the outlook. The prognosis is graver the less the amount of effusion required to obtain the febrile reaction. The less the reaction and the tardier its appearance the milder the affection. In the days following the primary febrile reaction the temperature may surpass that first obtained, or it may equal or not approach it, the severity of the affection being announced by the prolonged reaction. In case of a negative response, the amount to be reinjected can be increased from 1 to 2, 3, or 10 c.c. If there is no response after this large amount has been injected, and if the temperature remains unchanged or varies very slightly during the days following the injections, the prognosis may be regarded as extremely favourable. D.

Treatment of Diabetes Insipidus with Strychnine.—Ketby (*Ther. d. Gegenwart*, Berlin, August, 1906) found injections of strychnine nitrate extremely useful in three cases of idiopathic diabetes insipidus. He commenced with .5 mg., increasing every second day by .1 mg. to a maximum of .01 gm. The patients were three men from 31 to 36 years old. The subcutaneous injections were given daily for about a month in one case, and then the strychnine was given by the mouth for three days. The amount of urine dropped from 8,000 to 1,500 c.c., and all the symptoms permanently disappeared. In another case the diabetes persisted after the cure of a syphilitic brain trouble under mercurial treatment. Under the strychnine injection the amount of urine declined from 11,500 to 3,000 c.c. in 13 days, and the polydipsia vanished with the polyuria. This improvement was only temporary, however, as the symptoms recurred in two or three months. They subsided again under strychnine by the mouth. One female patient did not show any improvement under the strychnine. D.

Resume of World's Cancer Research.—Bainbridge (*Med. Record*, New York, Sept. 1, 1906) states that cancer occurs with the same essential characteristics throughout the vertebrate creation. There is a variety of conflicting evidence in reference to the influence of diet on the development of cancer. Cancer is comparatively rare in hot countries, especially in those whose inhabitants subsist largely on vegetable diet. With certain exceptions it seems to be prevalent where animal diet is mostly consumed. Black races are remarkably immune from cancer; yellow races are more prone to it; while the white races are the most susceptible. It occurs when the tissues are undergoing retrograde metamorphosis. Cancer is undoubtedly on the increase. The principal increase involves the alimentary tract. There are certain districts called "cancer belts." Such areas are usually low-lying and damp. Women are attacked by cancer far earlier and more often than men. More recent experimental work points to the cell as the essential element in the development of cancer. The parasitic theory is discredited by the Harvard Commission. The report of the Imperial Cancer Research Fund destroys all known theories of the origin of cancer, but proposes no new theory. Surgical treatment has been established on a firmer basis than ever before. D.

Family variety of Enuresis Nocturna.—This condition is most unusual, and Stern (*Weiner Klin. Randschau*, 1905, No. 22) has only been able to find one record in the literature at all similar to the group that is now reported by himself. All the children born in a first marriage were healthy, but all those born after a second marriage to a neurasthenic father suffered after their sixth year more or less from incontinence. The eldest daughter, now 16 years old, first became affected between her 8th and 10th year, but was ultimately cured by electrical treatment. In three sons, aged 14, 10, and 6 years respectively, the enuresis had persisted since birth. The oldest of these was the most troubled, and suffered also during the day from polyuria and from weakness of the visual sphincter. The fifth child, a 13-year-old girl, was healthy up to her tenth year, but from that time began to suffer at intervals. The mother had died of acute nephritis after her last confinement. The writer regards the above-described condition as a definite inherited neurosis. M.

The use of Cyllin in the treatment of Mediterranean Fever.—McNabb (Navy Blue Book) gives an interesting account of the treatment of 42 cases of Mediterranean fever which occurred on H.M.S. "Implacable." Numerous drugs were tried, but the only one which appeared to be of avail was cyllin, a derivative of creasote. It was administered in the form of tablets, each of which contained 3 minims. Of the 42 cases dealt with, 10 had neither pyrexia nor symptoms, and so were dismissed from the list. The remaining 32 McNabb divides into two groups: 24 cases which were not treated with cyllin, and 8 which were so treated. The average duration of illness in the former class was 70.6 days, in the latter 38.5 days. Twenty-one cases suffered from painful local affections, which occurred in the region of the sacro-sciatic joint in seven cases, in three in the sciatic nerve, and in the remaining 11 in various nerves, muscles, and joints. J.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

HERNIOTOMY.—Left duodenal hernia is rare of course, but quite a number of cases have been recorded—about 100 have been noted from time to time. For the points mentioned see "Ueber Intra-abdominelle Hernien und Bauchfelltaschen," by Brösike. Berlin, 1891.

R. WILSON.—Hypertrophic conditions of Luschka's tonsil may be regarded as a synonym, though perhaps not a happy one.

TRIPSIN.—Glycogen is present in many fungi, but in the large varieties it is consumed during growth.

DENS.—A good example of toothache "cure" has recently been patented and illustrates the point. It is a mixture of myrrh, alcohol, and chillies, capsicum, or other "pepper-like substance."

CANTABRIGIENSIS.—Your letter is under consideration.

THE TREATMENT OF RHEUMATISM, GOUT, &c., BY FANGO DI BATTAGLIA.

DR. HARRINSON, Physician to Smedley's Hydro, Matlock, writes us in reference to a letter which recently appeared in our columns on this subject, signed C. Vetter. He says, "My former statement that Fango di Battaglia is used at Smedley's Hydro, Matlock, as well as at the Royal Hotel Baths, Matlock Bath, I am prepared to stand by, and I can guarantee that the treatment has been given as well at Smedley's as at any other institution."

DISPENSER.—There is an Association of Women Pharmacists for supplying qualified dispensers. Address, the Secretary, Association of Women Pharmacists, Gordon Hall, Gordon Square, W.C.

L.R.C.P.—The circumstances make correct action very difficult. Without committing ourselves to a definite view in the matter, in the absence of fuller information, we should say it was highly indiscreet.

F.R.C.S. (Edin.).—The "Hammond" typewriter is a good machine, especially with the universal keyboard. Yes, you might do worse.

VAC.—An official illustrated guide and list of streets, boarding houses, and seaside and farmhouse apartments may be obtained from the Manager of the London and South-Western Railway. It is well got up and very useful.

R. A. G.—The word is seldom used, and is, as you remark, a mouthful for pronunciation. It is derived from the Greek, and is intended to describe a defect of vision, in consequence of which blue colour cannot be distinguished.

FOURTH YEAR.—The "Manual of Surgery" referred to is as popular as ever, and is not likely to be displaced, so long as the authors continue as in the past to keep it up to date.

MR. M. E. B. is thanked, but the contribution is scarcely suitable for the columns of this journal.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 10th.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street).—5.15 p.m.: Meeting.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus).—8.30 p.m.: Hunterian Lecture:—Dr. J. K. Fowler:—The Diagnosis and Treatment of Thoracic Aneurysm.

POST-GRADUATE COLLEGE (West London Hospital).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. X-Rays. 2.30 p.m.: Operations. 4.30 p.m.: Lecture:—Mr. C. B. Keetley: Opening Address of Winter Session.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m.: Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. H. L. Jones: Rodent Ulcer and its Treatment by Zinc Ions.

THURSDAY, OCTOBER 11th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square).—8 p.m.: Specimens will be shown by Mr. F. B. Jessett (President), Dr. H. Macnaughton Jones, and Dr. H. Overy.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms).—8.30 p.m.: Papers: Dr. A. Morison: The Cardio-Vascular State in Asphyxia Neonatorum and its Management. Mr. H. T. Herring: Easy Methods of Sterilising Urethral Instruments.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m.: Address:—Sir Halliday Croom: The Obstetrical and Gynæcological Relations to Exophthalmic Goitre.

POST-GRADUATE COLLEGE (West London Hospital).—2 p.m. Medical and Surgical Clinics. X-Rays. 2.30 p.m.: Operations Diseases of the Eye. 5 p.m.: Lecture:—Practical Surgery.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. C. Mercier: Some Aspects of Drunkenness.

FRIDAY, OCTOBER 12th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square).—8.30 p.m.: Address:—Mr. H. H. Clutton (President): Adolescent (late) Rickets (illustrated by lantern slides and cases). Followed by a discussion.

POST-GRADUATE COLLEGE (West London Hospital.—2 p.m. Medical and Surgical Clinics. X-Rays. Diseases of the Throat, Nose, and Ear. 2.30 p.m.: Operations. Diseases of the Skin. 5 p.m. Lecture:—Surgical Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m. Dr. St. Clair Thomson. Clinique. (Throat.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 p.m. Clinical Lecture:—Dr. Beevor: Cerebral Anatomy and Localisation.

SATURDAY, OCTOBER 13th.

POST-GRADUATE COLLEGE (West London Hospital).—10 a.m. Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. X-Rays. 2.30 p.m.: Operations.

Vacancies.

Kent and Canterbury Hospital.—House Surgeon. Salary £90 per annum, with board and lodging. Applications to the Secretary.

Sheffield (City of).—Visiting Medical Officer for the Schools under the control of the Education Committee and Assistant Medical Officer of Health for the City. Salary £400 per annum. Applications to H. Sayer, Town Clerk, Town Hall, Sheffield.

Sussex County Hospital, Brighton.—Senior House Surgeon. Salary £100 per annum, with board and residence, and washing in the Hospital. Applications to the Secretary.

Nottingham City Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with apartments, board, &c. Applications to the Medical Superintendent.

West Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to John H. Bonner, Secretary.

Kidderminster Infirmary and Children's Hospital.—House Surgeon. Salary £120 per annum. Applications to the Secretary.

The Stamford Hill and Stoke Newington Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with apartments and board. Applications to the Senior Medical Officer, 189 High Street, Stoke Newington, N.

Somerset Hospital, Cape Town.—Assistant Resident Medical Officer. Salary £200 per annum, with quarters and rations. Applications to David and Soper, Agents to the Somerset Hospital, Cape Town, 54 St. Mary Axe, London, E.C.

Manchester Royal Infirmary and Dispensary. Honorary Assistant Physician. Applications to the Chairman of the Elective Committee, on or before October 31st. (See advt.)

Appointments.

BAILIE, H. W., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Superintendent Medical Officer of Health of Belfast.

BERGIN, FRANK GOWER, L.R.C.P.Lond., M.R.C.S., House Surgeon at Bristol General Hospital.

EDWARDS, ALBERT DAVIES, B.Sc.Lond., L.R.C.P. and S.Edin., L.F.P.S.Glasg., L.S.A., Resident Medical Officer at the Cardiff Workhouse.

ESKELL, LOUIS BENJAMIN, L.D.S.Irel., Honorary Dental Surgeon to the Winsley Sanatorium.

GREEN-ARMYTAGE, V. B., L.R.C.P.Lond., M.R.C.S., Casualty Officer at the Bristol Royal Infirmary.

MACDIARMID, R. C., M.B., M.S.Glasg., D.P.H., Certifying Surgeon under the Factory and Workshop Act for the Alyth District of the counties of Perth and Forfar.

MORRIS, LEONARD NEWSOM, L.R.C.P.Lond., M.R.C.S., House Physician at the Bristol General Hospital.

PINNIGER, WILFRID JAMES HUSSEY, M.B., B.S.Lond., L.R.C.P Lond., M.R.C.S., Casualty Officer at the Bristol General Hospital.

SHAW, ERNEST H., M.R.C.S., L.R.C.P.Lond., Casualty Officer, Pathologist, and Registrar to the Metropolitan Hospital.

SMITH, FRANCIS SHINGLETON, M.C.Cantab., L.R.C.P.Lond., M.R.C.S., House Surgeon at the Weston-super-Mare Hospital.

STORRY, JAMES ALEXANDER, L.R.C.P.Edin., L.R.C.S.Irel., Medical Officer to the Dunstable and District Joint Isolation Hospital.

SYKES, ARTHUR, L.R.C.P.Lond., M.R.C.S., Resident Medical Superintendent at the City Asylum, Norwich.

WILSON, M. R. O., L.R.C.P.Lond., M.R.C.S., Assistant House Physician at the Bristol General Hospital.

Marriages.

FORSYTH—BURN-MURDOCH.—On Oct. 5th, at St. George's, Charlotte Square, Edinburgh, Noel Constable Forsyth, M.B., son of J. Forsyth, Esq., Quinish, Mull, to Dorothea, daughter of T. M. Burn-Murdoch, Esq., F.R.C.P.E., 14 Charlotte Square, Edinburgh.

Deaths.

CHILCOTT.—On Oct. 6th, at Highgate, Isabel Mary, dearly-loved wife of Arthur Chilcott, M.D. (Medical Superintendent St. Panoras Infirmary). Aged 36.

RAMSEY.—On Aug. 23rd, at Prahran, Melbourne, of pneumonia, John Ker Ramsey, M.D., of Prahran, aged 66 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, OCTOBER 17, 1906. No. 16.

NOTES AND COMMENTS.

Compensation for Workmen.

AMONG the many delicate positions in which medical men find themselves placed, the treatment of injured workmen is one of those demanding the greatest circumspection. There are, unhappily, needy solicitors who are only too ready vexatiously to put into motion the Employers' Liability and the Workmen's Compensation Acts, and medical men have to be wary lest they become the dupes of these enterprising attorneys. A County Court case heard at Southwark last week, in which a workgirl sued her employers for permanent damage to her finger, called forth from the judge some caustic remarks on the way this injury had been treated. There was a decided conflict between the medical evidence for the plaintiff and for the defendant, and the judge took the view that the defendant was in the right. After the injury the girl attended St. Bartholomew's Hospital, where a piece of steel was extracted from the finger, but she subsequently went to a private doctor, who appeared in due course to give evidence for her. The house-surgeon, who was called by the defence, alleged that a statement made by the medical men who appeared for the plaintiff to the effect that the finger was lengthened by five-eighths of an inch, was not the fact, and he even went so far as to say that it was owing to the unskilful treatment of the finger that it became thinner and looked longer. He averred that the pain the girl felt and the inability to move her finger were due to suggestion, hysteria, or fear, and needless to say the judge, taking this view, commented adversely on the plaintiff's medical advisers.

The Moral of it all.

Now here was a case, if ever there were one, in which a previous consultation between the medical men engaged on either side should have decided the matter one way or the other without appeal to Court. A finger either is or is not five-eighths of an inch longer than another, and a tape-measure would have settled the point in two minutes. Moreover, the graver question whether the finger was permanently injured, or whether the girl was merely neurotic, could no doubt have been cleared up at a meeting of the professional advisers of either side. In a word, the point was capable of decision on medical grounds, and with conflicting medical testimony no judge or jury could have decided it. If after consultation the point remained in doubt, the judge could have called in the surgeon attached to his district. But County Court judges have an insuperable objection to doing so, and consequently we find the severest censure passed on two doctors in open court on the evidence of a third, without anyone being in a position to decide who was right and who was wrong. These incidents are highly unfortunate.

P.M. Room Fiasco.

THE halfpenny paper furore over the Cardiff *post-mortem* room attendant has fizzled out ignominiously. The Health Committee of the Corporation properly ordered an investigation to be made as to the cause of the wild assertions made about the caretaker opening bodies at *post-mortems*, and Dr. Walford, the Medical Officer of Health who was appointed to make inquiries, reported that the man was given a good character by the practitioners for whom he worked, and that everybody found he was competent and diligent. The only thing recorded against him was that an assistant to one of the medical men in the town, who went to make an autopsy, on one occasion found the lungs already removed from the body. This, as Dr. Walford pointed out, was probably the result of a slight excess of zeal, and the attendant promised not to repeat the performance. One of the councillors, who seems to have been at the bottom of the affair, consequently looks rather foolish, and it may be hoped he will be more careful as to his facts before making a hubbub in the future. If anybody really wishes to discover a scandal in connection with mortuaries, we recommend to his notice the highly improper practice, prevalent in more than one district, of the coroner's officer pocketing the shillings from the doctors' guineas, and the equally reprehensible one of mortuary attendants putting difficulties in the way of practitioners who have to do *post-mortems*, till half-a-crown is produced for their benefit.

Derby Guardians and Vaccination Officer.

IT is highly regrettable that pro-vaccinationists and anti-vaccinationists cannot agree to differ in a philosophical manner; the subject of the protection of children from small-pox is far too grave a question to be made the shuttlecock of contending factions in local politics. As it is, certain magistrates hav

shown to a rather unwise degree the indignation that intelligent men naturally feel at the unreasoning prejudices of anti-vaccinators, and consequently have drawn official remonstrance from the Home Office on their heads. The anti-vaccinationists, on their side, are trying to strain the law in their favour, and the Derby Guardians last week entered on a piece of folly likely to be still more sternly visited. These administrators of the law were called upon to appoint a vaccination officer, and they made it a conditon of his appointment that he should not without their consent take proceedings against defaulters. Now as this duty of instigating prosecutions lies with the Local Government Board, this condition is patently *ultra vires*, and therefore not worth the trouble of making. The Local Government Board are not likely to abrogate their duty in favour of the Derby Guardians, and we expect soon to hear that there is trouble. The interesting fact about vaccination is that since the conscientious objector appeared on the scene in 1898, the numbers of successful primary vaccinations have steadily gone up.

LEADING ARTICLE.

MEDICAL INCOMES.

IT is one of the more hopeful signs of the times that the public press has taken up with some energy the question of what they term "doctors' incomes." For some time past the subject has enjoyed a recurrent prominence among newspaper topics. For various reasons the education of the public in this way is one to be encouraged, not less in the interests of the medical profession than in those of the community. Obviously it is of the utmost importance that the nation should be supplied with competent and honourable medical men. Moreover, it is an essential condition of the maintenance of those desirable qualities that there should be a reasonable prospect of making a livelihood from the practice of medicine. In other words, the legal creation of a highly qualified medical practitioner connotes the necessity of protecting him against illegal and unfair competition. In the correspondence above alluded to, "clubs and chemists" take a prominent position. With regard to clubs, it must be admitted that the unfair competitors come from within the ranks of the profession. It is difficult to determine the best plan of dealing with men who are ready to give their services at nominal fees and to resort to any trick in order to secure a patient. The General Medical Council has interfered in the case of medical aid societies, which make a profit out of the services of a salaried medical man. If the Council by any subtle extension of their specific powers could exercise a similar disciplinary control over the ordinary medical club, they would confer a great boon upon the profession. In his recent address, Dr. McAlister showed how the Council had in some cases created its own powers. Apparently it is only when asked to take such steps as the increase of direct representatives, of a one portal system of qualification, or of reform of the Council and of the Medical Acts that the Council plead *non possumus* with one accord. As regards the matter of unqualified prescribing, the competition of chemists has long since passed into the region of established scandal. The evil wrought upon medical men thereby, and the gross wrong inflicted upon the public, are no less deplorable than disastrous. The extent of this form of charlatan practice it is not easy to estimate, but in the aggregate it may safely be described as enormous. The plea of the chemists that they prescribe only in simple cases is futile. Who is to decide what is or is not the "simple" case? As every experienced medical man knows, it is precisely the trivial symptom that often affords the key to grave underlying disease. Take as examples the dyspepsia of early phthisis, the headache of refraction errors, or the mixed and manifold group of acute inflammatory conditions of gout, rheumatism, and allied rheumatoid states. Indeed, it may be stated generally that the recognition of the significance of minor ailments is one of the lessons that come late in the experience of the medical practitioner. The chemist, on the other hand, being trained merely in the nature and handling of drugs, is absolutely incapable of the proper differentiation and analysis of symptoms. To him all affections of the scalp, for instance, represent ringworm; all headaches, no matter whether due to anæmia, toxic disturbance, gross cerebral lesion, or errors of refraction, suggest to his mind some symptomatic remedy such as phenacetin or antipyrin. Scabies is often treated by him as eczema, and early pneumonia as "a touch of bronchitis" demanding a cough mixture in nine cases out of ten liberally charged with narcotic drugs; serious heart trouble is met with bismuth and pepsin, administered to relieve the attendant gastric symptoms; while failing cardiac compensation is unrecognised. Some day an enlightened public and an enlightened legislature will doubtless assess at its proper value unqualified prescribing of all kinds, and will take steps to confine medical practice to the legally qualified. Although any limitation of the kind would clearly be to the benefit of the medical profession, it would be a thousand times more economically valuable to the nation in the saving of life and limb that must be the inevitable result. The present stringent rules that guide, govern, and control the education and qualification of the medical practitioner are justified by the plea that they are demanded for the protection of the public. In spite of the recent jeremiad of the President of the General Medical Council, we venture to submit that the safety of the man in the street would stand on incalculably safer footing were he also protected against the machinations of quack prescribers, quack medicine vendors, and quack practitioners, and were the duty of suppressing illegal practices of the kind conferred upon the Council.

NOTES ON CURRENT TOPICS.

Sir Lambert Ormsby on the Medical Services.

The Opening Addresses at the various hospitals offer year by year good opportunities for instructing the public on certain matters regarding which medical opinion is valuable. Sir Lambert Ormsby acted wisely, therefore, in his address to the students of the Meath Hospital, in discussing some of the points wherein the medical services are still at fault. While admitting freely the great improvements which have taken place in the Army Service during the past few years, he drew attention to the several causes which have in recent years brought the Senior Service into unpopularity. It is necessary that, unless the Naval Medical Service is to pass into the disrepute until recently possessed by the Army Service, steps be quickly taken to remedy the grievances under which naval surgeons suffer. As the Service stands at present there is much reason for Sir Lambert Ormsby's advice to young medical men to avoid the Navy as a career. As regards the administration of the Medical Service of the Army, Sir Lambert Ormsby emphasised the absurdity of the present position in that the Adjutant-General, a military officer, is the head of the sanitary and hygienic department of the Army. The Director-General is merely a subordinate, whose representations may be passed over without anyone being the wiser. If the sanitary service of the British Army is to keep level with that of other countries, it is absolutely necessary that a skilled sanitarian should be at its head, not merely with information to know what is necessary, but with power to carry his plans into practice. It is well that the public should be fully impressed with the fact that the mortality of war has been in most cases a mortality of disease and not of wounds, and has been therefore a preventable mortality. The care of the health of the soldier is the first necessity of a successful campaign, and it is essential, therefore, that the officer charged with that care should be fully responsible, and, in his own department, supreme.

Consumption in Ireland

Mr. McArdle has done a good service in the fight against consumption in Ireland by his stirring address at the opening of the session at St. Vincent's Hospital. He has been able to attract public attention to one of the most serious problems affecting Irish life at the present day, and we cannot but believe that when once the public realise the gravity of the problem, nothing will be allowed to stand in the way of its solution. Last year 11,882 people, mostly young men and women, died from tuberculous diseases in Ireland. If the public can be made to realise that that mortality is, in the main, preventable, then we are sure the community will fail in nothing which tends toward prevention. Mr. McArdle went on to point out some of these methods, and in particular he urged the establishment of a dispensary for consumptives in Dublin. This dispensary would undertake the treatment of consumptive patients, would instruct them in the methods of preventing the spread of the disease, and would when necessary follow them to their homes, and safeguard the health of their friends. It would, of course, be equipped with all necessaries for the diagnosis and modern treatment of all forms of tuberculous disease, and it would have a strong and competent medical staff. Mr. McArdle's suggestion has been well received by the press, and it rests to a great extent with medical men to keep the project well to the fore.

Hospital Staffs and Outside Visits.

As a rule, the man in the street utterly fails to regard the medical charities from an economic point of view. To his mind, those institutions exist for the relief of sickness and bodily suffering of all kinds, and he refuses to recognise the rights of the medical profession in asserting a prior claim upon those who are able to pay proper fees for medical services. Last week, his eccentric habit of mind was brought into grotesque prominence at a London inquest, where bitter complaints were made because the Westminster Hospital would not send out one of their medical staff to see a man in a neighbouring office who had suddenly collapsed from heart failure. An account of the case will be found in another part of the present issue. It would, indeed, be the last straw upon the already intolerable burden of hospital competition were the medical charities to allow their resident or consultant staff to visit sick persons outside the hospital walls. It will be fresh in the minds of readers that some of the Charing Cross Hospital house surgeons and house physicians visited the scene of the recent accident at the adjoining railway station, where the fall of the roof killed a number of persons. Very rightly, as we think, the attention of local medical men was called to the innovation, which was generally condemned as unwise even in the face of so grave a disaster.

Royal College of Surgeons o England.

At a quarterly meeting of the council, held on Thursday, Mr. Henry Morris, president, in the chair, the report of the council to be presented to the annual meeting of Fellows and Members of the college on November 15th was approved and adopted. During the year with which the report deals the following diplomas have been issued:—Membership, 423, Fellowship, 42, Licence in Dental Surgery, 87, and Diploma in Public Health, 33. During the past year the library has been open 271 days, and the number of readers has been 11,267. The deaths of 20 Fellows and 264 Members of the college have been reported. An honorarium of £100 was presented to William Pearson, the prosector in the museum of the college, "in recognition of his valuable work and of his having completed 50 years in the service of the college." It was decided to publish a revised edition of Part I. (Man) of the Osteo-

logical Catalogue. The loan of museum specimens to the Army Medical Department for examination purposes was renewed for another year. Mr. G. A. Walker, until lately a student at Epsom College, and now at the London Hospital, was nominated by the council as the fourteenth Jenks scholar.

Side-Lights on Medical Education.

WE have commented more than once on the misleading nature of the figures published from time to time by one of our contemporaries under the title "Side-lights on the Medical Profession." These figures, extracted with variable degrees of accuracy from the returns of the examinations for the different Service examinations, are supposed to give some information as to the quality of the education supplied by the different medical schools of the kingdom. That conclusions arrived at on such data are liable seriously to mislead the public was well exemplified by the letter addressed by Dr. Ryan, a graduate of the Royal University, to the *Irish Times* last week. The avowed intention of this communication was, from a quotation of the figures referred to, to depreciate the reputation of the medical degrees of Dublin University, as compared with the qualifications granted by other bodies. Unfortunately for Dr. Ryan's contention, Professor Dixon was able to show in a letter to the same paper that, whereas prior to 1905 the Royal University stood second to the English universities in the percentages of candidates qualified and commissions won, during the last two years Dublin University has headed the list of universities of the kingdom. Moreover, Dr. Dixon is also able to state that about half of the successful Royal University candidates in recent years had been members of the Dublin University Service Classes. We do not ourselves regard the Service figures as sufficient data for any conclusion as to the education given at the different schools, and we think it unfortunate that an attempt should be made to use such untrustworthy weapons to attack the reputation of an ancient and liberal seat of learning.

"Prejudice and Ignorance."

IT is one of the results of the campaign of inuendo and vituperation conducted against hospitals by certain people who profess and call themselves humanitarians, that the poor conceive the idea that these beneficent institutions are laboratories for surgical experiment on helpless patients. People who prate on platforms and bluster in the correspondence columns of the press—to their own magnification—might possibly reconsider their actions if they were brought to hospital wards or the cottages of the poor and heard the house-surgeon or general practitioner pleading with ignorant and prejudiced parents for the life of a child. "We don't want 'im cut about," and "We ain't going to 'ave 'im experimented on by the doctors"—these and such phrases as these are among the commonplaces of practice among the poor. Medical men know well enough whence these ideas come, and they know how difficult it is to overcome them. At an inquest recently held at Hampstead by Mr. Schroder on a child who died of meningitis, the mother said she had taken him to the Hampstead Infirmary, but would not let him be taken in as an in-patient. A doctor was called in later and advised that the child should be sent to hospital to be operated on if necessary. Again the parents refused, in spite of the doctor's entreaties that the patient should be placed under skilled observation with a view to operation. After hearing the evidence the jury returned a verdict in accordance with the medical evidence, and added that in their opinion death was accelerated by the parents' neglect to follow the doctor's advice, and that such neglect was due to prejudice and ignorance. We would that this finding could reach all those who delight to villify hospitals.

Bond Street, Beware!

PEOPLE who deal in unqualified medical practice play with edged tools, and sooner or later they generally come to grief. "Beauty Doctors" are the craze of the moment, and with straps, ointments and washes the only harm they are likely to do is to impoverish the vain, insipid creatures who resort to them for advice. But when it comes to special treatments, the removal of hairs, massage of the face, and blowing steam on to the skin, there are potentialities of physical damage which they are foolish to risk—as their patients are to submit to. An amusing case has just been tried in New York in which poetic justice was visited on the folly of a beauty patient. The lady in question was the wife of a fashionable dentist, and, being afflicted with "superfluous hairs," *alias* a moustache, she attended at the saloon of a "beauty doctor" in Philadelphia for treatment. The latter apparently was foolish enough to use carbolic acid for removing the hairs, and the patient was severely burned about the face. Indeed, she so far lost whatever remnants of good looks she had previously, that her husband lost what remnants of love he had for her, and he gaily entered on an illicit liaison with a school-teacher. The wife, having lost her complexion before, now lost her temper; indeed, she went so far as to horsewhip the interloping mistress. But the husband's attentions continued unabated, and finally divorce proceedings were instituted against him, and an action for loss of her husband's affection against the "beauty doctor." But during the trial of the latter suit a reconciliation took place between husband and wife, and the former was able to testify that it was all through the "beauty doctor" that they had been estranged. If every woman who was disappointed in her beauty-treatment sued the amateur doctor in whose hands she was, we fancy several shutters would go up in several well-known establishments.

Medical Motoring.

At Gloucester Petty Sessions last week a local medical man was fined £1 and costs for driving to the danger of the public on a certain date. The speed was stated to have been twelve to fourteen miles an hour, a dangerous rate for crowded thoroughfares, where the offence was committed. The defendant stated that his steering gear had gone wrong, so that he was not able to control the motor properly. The question of speed is one of growing importance all round, and now that motors are being widely adopted by medical men it has an increasing professional interest. If a motor be defective it is certainly unwise to drive it through any streets or roads, be they in town or country, for there is no more dire and disastrous Nemesis than that which sits behind such a car. Any medical man availing himself of this species of locomotion should become familiar with every part of the machinery, so that he may instantly detect any departure from the normal. Under proper management a motor is simply invaluable to any medical practitioner in busy practice, more especially, of course, to those who habitually cover long distances.

Juvenile Criminals.

All medical men interested in criminology will regret the retirement of Mr. Legge from the post of Chief Inspector of Reformatories and Industrial Schools, especially when they read his last report which has just been issued. For in it they will see that these schools and institutions, which are of the highest value to the country, have been under the guidance of an enlightened and sympathetic administrator, and of such there are all too few in the higher ranks of the Civil Service. In spite of the improvements in these schools which have taken place in the last few years, the fact that a vast amount remains to be done is patent, for not only is the number of convictions of young people for indictable offences on the increase, but, what is more disappointing, the number of reconvictions in England is so also. Mr. Legge deplores the apathy which pervades authorities with regard to the use of truant schools and to committals to industrial schools, for, as he points out, good, far-reaching and permanent results are only to be expected if a sound and prolonged probationary period is enforced. It is not to be wondered at that difficulties are encountered in placing these juveniles, who start out in life under a cloud, in suitable employment, and that they are not particularly welcomed. Many of them, of course, are abnormals and can never be expected to fill normal posts in society, and it is a pity that special colonies cannot be founded where under supervision they might do good service. At present the bad ones encumber the opportunities which would otherwise be open to those who have recovered from the early stigma, and it is difficult for the latter to have a fair start. Even the mercantile marine, which provided a promising career for many, is becoming closed to the industrial and reformatory boys who are trained on special ships for a seafaring life, and the naval authorities give them no encouragement. Preventive psychiatry, if the term may be allowed, is a branch of preventive medicine that must come more and more to the front as society becomes better organised and more fully aware of its responsibilities.

Servants' Bedrooms.

Much is heard nowadays about the advance of sanitation; correspondingly little is heard of its absence from the modern servant's bedroom. On this matter it is impossible to write too strongly. We say deliberately that the bedrooms provided for servants in many modern flats we have visited are unfit for human habitation. They are frequently so dark that gas or electric light has to be used all day; some have no ventilation except a window opening into a passage; and most of them are so small that it is impossible for the servant to get anything like an adequate quantity of air. If such rooms were provided in workmen's dwellings they would certainly not be passed by the medical officer of health, but being provided in flats rented at anything from £50 to £500 a year, presumably they do not come under the ken of the health department. Landlords apologise for want of light by saying that the servant only sleeps there, but it is noticeable that many of the kitchens are equally dark and insanitary. Young girls who are put into these ghastly traps become anæmic and sallow, and either contract tubercle and die, or live to be the weakling mothers of puny, rickety families. It is a platitude to assert that no room should be occupied by human beings which has not openings for the entrance and for the exit of air and which does not permit of the sun's rays reaching every corner, but it is equally a platitude to say that these considerations carry no weight whatever with the proprietors of many modern London flats. The new clauses of the Housing of the Working Classes Act, 1903, must surely be applicable to such buildings as these, and medical officers of health and all who value the health and happiness of this generation and the next should combine to have closing orders enforced against these barbarous and pestilential dungeons.

Sir Francis Laking, Bart., Physician in Ordinary to His Majesty the King, was sufficiently convalescent to be removed last week from his London residence to the Isle of Wight.

Dr. John Cameron, of Liverpool, who died a few weeks since at the ripe age of eighty-eight, has left by will property to the value of £54,400, of which he bequeathed £1,000 to the Royal Southern Hospital, Liverpool. Dr. Cameron was for fifty years a contributor to this journal.

On Saturday last the Regius Professor of Medicine, Dr. Osler, opened a new wing at the Acland House, Oxford, erected in memory of the late Mrs. Acland and Sir Henry Acland, for many years President of the General Medical Council

A CLINICAL LECTURE

ON

THE THERAPY OF BASEDOW'S DISEASE.

By PROFESSOR SCHLESINGER, M.D.,

University of Vienna.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

IT has occurred to me that a subject of such supreme importance as exophthalmia, a disease affecting the throat, heart, eyes and nervous system, would not be without interest to medical men, even though it were only to recapitulate the prominent features of the disease; but the treatment of such an obscure disease is of greater importance still. In offering advice to the profession it is necessary to commence with the early symptoms of the disease.

In the early stage of Morbus Basedowii a variety of phenomena make their appearance, but the most important for the physician is the rapid and persistent loss of body weight; even several kilogrammes may be lost before any suspicion of a neoplasm flashes across the mind of the attendant. Such events are not uncommon in daily practice, and cannot be too often repeated to be of use in our daily vocation; even the cardiac symptom associated with emaciation may be neglected as the preliminary warning to the succeeding disaster.

Supposing we have diagnosed the disease at this early period, our duty is to arrest its progress if possible. Drugs such as thyroid gland, ovarian tabloids, or iodide preparations will not give immediate relief, nor is this so available at this stage of the disease as a modification or correction of diet and habit. First of all prohibit smoking and drinking; if the latter must be retained let it be moderate, in small quantities of beer. All gaseous foods, or foodstuffs likely to produce flatus, should be forbidden, and with this principle in view every form of milk diet should be encouraged. The open-air rest cure is as true in this disease as in tuberculosis, and should be enjoined in some form. The hydropathic treatment must be proceeded with carefully if prescribed at all; and should not extend beyond luke-warm baths with cold effusions to the neck by means of a sponge or towel. It would be better to commence with separate parts of the body, gradually increasing the area till Shepmann's douche could be applied to the spine with tepid water. When the heart is painfully throbbing, the application of some cold object such as a cold-water bottle of india-rubber, aluminium, lead, or vulcanite. Winternitz is strongly in favour of the hydropathic treatment on the ground that it improves the appetite and hastens metabolism. It has proved successful in Winternitz's hands, but it must be undertaken with great care. Galvanisation may be commenced later, with suitable medication. It often happens that a combination of these remedies has more effect in relieving the patient than any single course, however rational it may seem to the physician. Though bathing, for instance, is dangerous, yet it will give instant relief to the vexatious feeling of heat. The great weakness and danger of sudden collapse are the first objects of care, while complications increase the difficulties. Anything, therefore, that will allay pain, improve the appetite, increase metabolism, and add to the body weight should be the aim of the attendant. All observers agree that the increase of body weight is a good measure of improvement, indicating the close of the acute stage.

The acute stage is sometimes doubted in Morbus Basedowii, or presumed to be an accident, but within the last two years I have had occasion to record four of these. Commencing with three or four tablets of the ovarian gland has a wonderful calming effect on the acute condition.

During a single year so many remedies have been prescribed for the cure of Basedowii that the half of them are now forgotten, and will probably never be heard of more. There is one opinion dominant that the disease has its origin in the thyroid gland, while Mœbius has declared from the beginning and maintained that it was due to a hyper-secretion or excited activity of the gland. Whatever the theory of causation, two hypotheses are accepted in the treatment—viz., that the system is injured in some way by the altered function of the gland; and a portion of the gland or morbid part of it should be removed to cure the patient, but experience proves the latter to be fraught with difficulty and danger.

The first indication would be to neutralise the poison, and to effect this Lanz fed his patients on goat's milk whose thyroid gland had been removed in the hope of neutralising the hyper-secretion in the diseased gland. Lanz has put on record some wonderful cures by this treatment, which seems logical, as it certainly must deprive the blood of the irritant that increases the gland. This form of treatment led to a powder of milk being put on the market under the name of "Rodagen," which supplied the principle conveyed by the thyroid-ectomised goat's milk. The necessary quantity of goat's milk was ¼ to ½ of a litre, and the corresponding dose of "Rodagen" was one to two grammes daily; larger doses were not easily borne by the stomach. My own experience of this powder was not so favourable as literature painted it. During the last year I have used the milk of thyroidectomised goats both in hospital and private practice for months together with fairly good results. The treatment is not curative in action, but ameliorative. The patient is certainly generally improved, but the Basedowii symptoms still remain unchanged. Another practical difficulty in the treatment is the short time that the goat gives milk after the thyroid gland is removed, often disappearing in a few weeks after the operation, also is always reduced in quantity after removal. Last year we had to remove the thyroid from three goats in two months to supply three Basedowii patients with

the necessary amount of thyroidectomised milk, but our supply running out left us without results. Rhodagen is a preparation so expensive, and in my opinion so inoperative, that I cannot recommend it, although I have used a considerable amount of it. My own experience of the milk of thyroidectomised goats and Rhodagen is negative, and not worth further consideration.

The fashionable blood serum could not escape observation in this obscure disease! Sheep have had the gland removed and the serum applied subcutaneously to the patient with no better results. There is still a blood serum on the market under the name of Antithyroidin Mœbius, reputed for its efficacy in Morbus Basedowii, but there it ends. Mœbius reports many successful cures. I have used three to five grammes daily, gradually increasing to four and five grammes, with occasional periods of rest. I have also used it by the mouth, and given it warm in wine, which is more efficacious. In this way I have found the patients express themselves as very much better. The rapid pulse became less, the thyroid diminished, and the body weight increased. With all the preceding treatment there are often sequelæ, more fatal than the disease produced, which deserve careful attention, but in my own use of the sheep's gland by the mouth I have not observed a single adverse symptom, which is something to say in commendation of using the sheep's thyroid per os; but again I repeat that the price is not commensurate with the results where the case is chronic. In acute cases the thyroid might be, and is, administered with success, but where it is of long standing the benefits are slight.

We now come to the operative treatment, which has also gone through many transformations. Kocher recommends the removal of the morbid portion of the gland only, and prescribes certain methods of operation that are necessary. Then we have others recommending a combination of methods and tying the nutrient artery after partial excision of the struma, with no better success. All their statistics testify that we are no nearer curing the disease than when it was first observed, although an operation certainly ameliorates the symptoms, but the operation itself is fraught with danger, as the high mortality shows. Operating should only be advised where the cases are so bad as to disable the patients from following their respective duties, and after being fully informed of the dangers attending the operation. When the exophthalmia is severe, with obstinate keratitis and much impairment of health, associated with wasting and cachexia, and every drug has failed, operation may be prudently advised as the only course left for hope. Operating relieves many of the severe symptoms such as the exophthalmous and cardiac, and is worthy of trial in severe cases.

The injection of drugs into the gland itself has its admirers, but reports do not give us much confidence in that direction. The favoured drug is iodoform ether, which has occasionally met with some success.

The Röntgen rays applied directly to the gland has been practised by my second assistant with great success. Dr. Weidermann has treated five cases in this way with great promise; all of them increased in weight within a very short time, but the Morbus Basedowii conditions were in no way influenced. As soon as the application of the rays ceased, the patients began to emaciate and fall back into the former state.

Having given you the latest treatment with my own hopeless suggestions I shall now fall back on our earler procedure as the most satisfactory. The time-honoured hydropathic treatment does more to calm the heart and relieve the nervous irritation than any of our more recent novelties. Along with this may be combined the electric treatment in the galvanic form with great advantage. The current may be passed through the gland and sympathetic nerves by placing one electrode in front of the thyroid and another on the spine, or the poles may be placed on either side of the gland itself. Allowance must be made after repeating the treatment for the loss of cutaneous resistance, or you burn the patient severely. Although sceptical of electric treatment generally I must confess that I have seen the frequency of the pulse reduced and the gland diminish after a course of treatment of this kind. With even two or four celled baths I have seen most of the symptoms disappear—even the diarrhœa and palpitation.

Change of residence was once held as the primary feature in all treatment, and particularly to elevated localities — even mountains had specific virtues. I have had patients transferred to mountains over a thousand metres high who became very unwell; sleepless, palpitation, etc. The best results we can get from elevated positions are to be found in those who do not worry nor take long walks, but who rest, take their food well, and remain quiet and contented; these are often greatly benefitted by the change.

All of them, however, after a month's residence at home return to their former condition; therefore the hill hospice must be a permanent residence for Morbus Basedowii.

The opposite has also been pressed. Sea-side residence and sea-bathing has its votaries in this trying disease. The temperature should not be too low and the time of exposure short, not extending beyond a few minutes, as paralysis is easily induced when the shock is prolonged and the cutaneous surface stimulated. Sea voyages are beneficial, as the patient can sit on deck in fresh air and improve the appetite without undue exertion. A little walking exercise does no harm; it is forced walks where a constant strain is kept up that does the injury. Hence driving and touring should be encouraged, as change of scenery is of immense value to the patient.

I need hardly trouble you with drugs; reported cures are legion, but they have all failed in my own hands. I think it will be more profitable for me to relate the drugs that certainly do more injury than good. The first and most formidable of these is the thyroid gland, which probably will be the first drug offered. The history of this treatment proves that in initial cases when the thyroid is given the disease rapidly goes from bad to worse; hence the necessity of carefully guarding against fatal danger.

Ovarian preparations have no better history to relate. The case I have treated with them produced many complications that more seriously endangered the patient's life than if they had been avoided. The iodide preparations are equally dangerous, and their benefits very problematic

even in the best form they can be given. The thymus preparations are free from many of the dangers mentioned, but the results are very doubtful. Digitalis is another drug often prescribed, doing no harm and as little good except in feebleness of the cardiac muscle, but it has no influence on the tachycardia; in strengthening the muscle it is important.

I shall now enumerate a few of the drugs that may be given:—Phosphorus, arsenic, strychnia, quinine, and iron where anæmia is present.

Kocher speaks very highly of the use of phosphorus; his results are confirmed by many other investigators. I can vouch for more good being obtained from the use of phosphorus than any other drug. I usually prescribe half a milligramme in a pill, and give two daily. The same quantity of phosphorus may be given in cod-liver oil.

℞ Phosph., 0.01 gramme.
Jecor ascelli, or lipanin, 100 grammes.

This is well mixed, and two dessert-spoons given daily. A gramme or two of the phosphate of soda may be given daily with the same benefit. It might be noted here that lipanin is an emulsion of olive oil, 6 per cent., which has a better taste than cod-liver oil or jecor ascelli.

In the prescribing arsenic I have used for several years the cacodylates for their less poisonous properties. I am favourably inclined towards atoxyl as a subcutaneous injection: a ten to twenty per cent. watery solution injected intramuscularly twice a day. I have never seen intoxication with the drug when prescribed in this form. With natrium cacodylicum we are not so free from the danger of poisoning, but one to two centigrammes may be given by the mouth or intermuscularly without danger. There are other private preparations such as "Metharsinat," some of them perhaps good in their way, but giving off objectionable exhalations. In anæmia the ferrum cacodylicum may be given by the mouth, as subcutaneously it produces severe pain. The dose is one to two centigrammes per day, in the form of pill or watery solution.

Strychnia as a tincture may be given with quinine with great benefit The following pill is useful:—

℞ Ext. nucis vomici, 0.4 gramme.
Quin. muriatis, 1.5 grammes.
Ext. centauri, 2.0 grammes.
Ex. taraxici, q. s.
Fiant pilulae 50.

Signatur: Three pills to be taken daily.

In addition to these general tonics it may be necessary, in many cases, to soothe and calm painful symptoms. The foremost in this class of drugs is bromine. Any of the preparations may be used, but my own experience favours the following mixture:—

℞ Ammon. brom., 0.2 grammes.
Codeia phosph., 0.1. grammes.
Sodium brom., 1.0
M.

Signatur: One to be taken three times a day.

In conclusion, it may encourage us to persevere in our efforts with the knowledge gained during the last decennium, as I am yet hopeful of obtaining better results than we have secured in the past by adopting less dangerous methods with better success in the treatment of Basedowii.

NOTE.—*A Clinicol Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by Francis J. Steward, M.B., M.S.Lond., F.R.C.S.Eng., Assistant Surgeon to ana Surgeon in Charge of the Throat Department, Guy's Hospital; Assistant Surgeon Hospital for Sick Children, &c., on "The Surgical Aspects of Tubercular Peritonitis." Lecture delivered at Guy's Hospital, May 25th, 1906.*

ORIGINAL PAPERS.

ACTINOMYCOSIS OF THE VERMIFORM APPENDIX. (a)

By THOS. H. KELLOCK, M.A., M.D.CANTAB., F.R.C.S.ENG.

Surgeon to Out-patients at the Middlesex Hospital; Surgeon to the Hospital for Sick Children, Great Ormond Street.

THE author first pointed out how much more frequently actinomycosis or streptothricosis, as the affection should be preferably termed, was recognised since more modern methods of examination had been employed. The affection, which was formerly expected to attack the jaws, liver, and lungs almost exclusively in persons whose occupations and lives were followed in the country, was now often recognised in many other parts of the body and in persons of various occupations and forms of life, town as well as country. The star or ray formation was not always present, and its absence must frequently have led to a negative diagnosis when the affection would have been recognised by proper staining.

As the fungus of streptothrix generally enters the body by the alimentary or respiratory tract, and has a great disposition to insinuate itself along the ducts of glands opening into these, it is easy to understand that the vermiform appendix should fairly frequently be attacked when the organism has travelled along the alimentary canal as far as the cæcum.

From the number of reported cases, actinomycosis of the vermiform appendix would appear to be a not very uncommon form of disease of that organ. An investigation of the records at the Middlesex Hospital showed that during the last three years seven cases had been under treatment in which the presence of a streptothrix had been demonstrated. The notes of two cases were read in which septic infection had been superadded to the streptothrix, in both of which portal pyæmia and streptothrix abscesses in the liver had been found *post mortem*, and in one a similar affection in the pancreas and pleura. In three cases the disease had been limited to the neighbourhood of the appendix, whilst in two this had been associated with an abscess presenting through the abdominal wall at some distance from the appendix region. A streptothrix infection of the vermiform appendix might thus be met with under two forms—the one simple, the other in which a septic infection had been superadded. In the first the condition is difficult to distinguish from an ordinary case of appendicitis, but in the second the patients were often extremely ill, and rigors and septic pyelophlebitis, both rarely seen in cases of ordinary suppuration about the appendix, seemed to be relatively common. These two forms of the affection were similar to

(a) Abstract of Paper read before the Medical Society of London, October 8th, 1906.

what is sometimes seen when the disease occurs in other parts of the body, such as the cheek. Attention was called to the tendency of the abscesses which form to burrow, and point at a distance from the original seat of the disease, and a comparison made to what often occurs in the same affection of the lungs.

The question was raised as to whether the so-called secondary streptothrix affections of the liver were really conveyed thither by the blood-stream, or whether they were not really an independent infection from the alimentary canal; in one of the reported cases the discovery *post mortem* of a streptothrix abscess in the head of the pancreas was quoted as an argument in favour of the latter view. The points that would be likely to be of help in arriving at a diagnosis in the simple cases would be a long history of slight indefinite pain in the region of the appendix, a relatively large amount of induration, and, if operation were performed, the small quantity of broken-down material found; in suppurating cases the occurrence of rigors early, and the pointing of abscesses at a distance from the appendix region.

The treatment should be both constitutional and local. In the simple cases the best results follow removal of the appendix and as much of the affected surrounding tissue as possible, combined with treatment by large doses of iodide of potassium. The suppurating cases are more serious, and little benefit is likely to be derived from the use of drugs until the septic condition has been dealt with by ordinary surgical measures, and it was pointed out how exactly this coincided with what is experienced in dealing with the affection as it occurred in other parts of the body.

TUBERCULAR CERVICAL GLANDS. (a)

By JOHN MARNOCH, M.A., M.B., C.M.,

Surgeon to, and Lecturer on Clinical Surgery at, the Royal Infirmary, Aberdeen.

The recent enormous advances in Abdominal Surgery have led to the everyday performance in this domain of operations which are of absorbing interest both to operators and onlookers, and the result is that an amount of attention is now bestowed upon this department of surgery which twenty years ago was never dreamt of. Moreover, as a direct sequel, medical literature now teems with reports of operations, generally successfully performed, on almost every abdominal organ, for conditions and diseases which not so very long ago were left severely alone as being beyond the pale of surgery. However fascinating this field of work is, it has one drawback—namely, that it diverts attention from, and belittles the importance of, the surgical affections more frequently met with in practice.

Among these affections none is more common than enlargement of the neck glands from tubercular disease, and in some of its varieties none is more troublesome both to patient and doctor. The patience is tried, and in the case of the surgeon his operative skill as well.

Clinical Features and Indications for Operation.

It may be useful, then, to recall some of the clinical features of tubercular cervical glands and their surgical treatment, especially as the indications for operation and the best method of carrying it out, thanks mainly to the work of Watson Cheyne, have emerged from a somewhat chaotic condition, and may now be regarded as resting on a sound scientific basis. And yet it is very doubtful if these indications are as well known as they ought to be, for it is not an uncommon experience for cases to be sent to the surgeon that are either quite unsuitable for operation, or that have been allowed to drift into a state which prevents the best results being got from surgical treatment.

Before considering how glands which have actually become tubercular should be dealt with, some reference must be made to those enlargements which are dependent on irritation in the structures anatomically related to them. When one considers the large areas drained by the lymphatics of the neck, and how frequently inflammatory lesions are present in some of these, as, for example, in the mouth and throat, it is not to be wondered at if glandular enlargement takes place in the neck quite often apart from tubercular origin. But although this is so, it is of prime importance that these swellings should be carefully treated, for it is now well known that glands which enlarge primarily from this cause may later on become tubercular unless the source of irritation be removed. Whether the inflamed glands form a suitable nidus for the tubercle bacilli already in the bloodstream, or whether the organisms gain entrance at some breach of surface about the mouth or throat and pass on to the glands, is a debatable point. There seems to be considerable evidence in favour of the point put forward by Sims Woodhead—namely, that the tonsils and adenoid tissue of the throat are the first to meet the tubercle bacilli, and that if healthy they are capable of giving an account of a moderate number of the invaders, but that if they are debilitated by repeated attacks of inflammation they lose their powers of resistance and permit the organisms to pass on by the lymphatic vessels to the glands, in which they settle. Whatever the explanation may be, the fact remains, as already stated, that these inflamed glands may ultimately become tubercular. It behoves us, then, whenever cases of enlargement of the neck glands, especially in the earlier stages, present themselves for treatment, to make a thorough examination of the areas drained by the glands, and to remove every possible source of irritation. This is a point that cannot be too strongly emphasised, as it not infrequently happens that cases are sent up for operation upon the glands when what is really required is the removal of an offending tooth or hypertrophied tonsils and adenoids. Indeed, I have even seen treatment applied to the occipital glands which were swollen from the irritation of an eruption of the scalp. Early removal of the exciting irritation quickly causes these glands to subside and give no further trouble.

Turning now to tubercular glands, considerable confusion has arisen in connection with their operative treatment, mainly, I think, from the impression that in their case the indications were of a special and exceptional character. This is really not so, for if allowance be made for their exposed situation, the indications for operation are essentially the same as in most other tubercular diseases, as, for example, in joints. No one nowadays thinks of temporising with a joint which is the site of abscess or sinus formation. Fortunately, in the surgery of joints a more general recognition of the value of prompt operative interference under such conditions obtains; and yet when abscesses or discharging sinuses are situated in the neck, less compunction is often felt in leaving them alone. Why should a softening or broken-down gland be left to nature unaided any more than a suppurating joint? It is quite true that the joint affection is a more disabling thing than the discharging neck, for while a young adult with the latter can often continue at work, with the former he is obliged to lay up. The mere fact, however, of these gland patients being able to follow their occupation is no justification for leaving them insufficiently treated. Many of them at the expense of a week or two's work can by operation be put into an infinitely better state for their occupation than they were when kept below par by continuous discharge. Besides, the cosmetic result after operation is not to be compared with the puckered, drawn, irregular cicatrices of nature. The occurrence, then, of suppuration, with or without sinus formation, is the first indication for operative interference.

(a) Abstract of a Clinical Lecture delivered at the Aberdeen Royal Infirmary.

The next indication—namely, when the glands are causing deformity—is more peculiar to the neck on account of its exposed position. Generally speaking, when tubercular glands have become large enough to cause an unsightly tumour, softening has set in and quite frequently the inflammation has spread outside the capsules to the surrounding areolar tissue. This has the effect of obscuring the outlines of the individual glands by matting them together and at the same time rendering them fixed and immobile. But there is another way in which the outlines may be obscured and in which a bunch of glands feels almost like one tumour with a uniform even surface—namely, where they lie beneath the sterno-mastoid muscle. Here, of course, the glands are situated at a considerable depth, and the thick elastic muscle spread over them prevents the palpation of the individual glands and produces the ugly pig-like neck one so frequently sees.

The next type of case that requires operation is where the glands, although not large, are infecting those in the immediate neighbourhood. Such cases require close and frequent watching, and if sent away for climatic treatment must either be put under the care of a medical man near their residence, or, where this is not possible, be brought back at short intervals for examination. The reason is that tubercular glands of the neck are somewhat erratic in their rate of enlargement. While some gradually subside under general treatment, others may remain stationary for a time and then rapidly enlarge and infect others near them.

You will observe, then, that the cases in which operation is to be recommended group themselves into three clinical types: first, where there is suppuration or sinus formation; second, where deformity is caused; third, where the disease is progressive in character, fresh glands becoming infected.

EXAMINATION OF THE NECK.

The neck should be examined from two positions, namely from the front and from the back, and of the two the latter is the more valuable. Standing behind the patient one can ascertain by palpation the extent, consistence, and mobility of the glands, much better than from the front, and this method of examination ought never to be omitted in any disease of the neck characterised by tumour formation. The examination should be conducted also with the head in different positions so as to relax or make tense, as occasion requires, the various structures of the neck. Thus, in order to ascertain the full extent of glandular invasion, say in the anterior triangle, the head should be flexed, and it will be found that the fingers can feel deeply beneath the sterno-mastoid. On the other hand, a better idea of the consistence of the swellings can be got with the head in the extended position. Now, it is frequently no easy matter to be able to say whether glands are softening or not. One obvious reason for this is the depth at which they often lie. Then, again, softening may have taken place in the centre while the cortex is quite firm, and lastly, a whole gland may have completely liquefied but the intact capsule is so tightly distended that it closely simulates a solid gland. Experience, however, will enable you to recognise softening, and I should say that in any case where you are in doubt whether it is present or not, you will be pretty safe to conclude that it is. I would strongly urge you to palpate these cases in the wards before they come to operation, and then, after excision, to split the glands open and examine them for yourselves. I am sure you will often get a surprise by finding that glands which you thought were solid are in an advanced state of liquefaction.

From an operative point of view it is of considerable importance to ascertain whether the swollen glands belong to the superficial or deep set. At the upper part of the anterior triangle especially, a mass may appear to be quite superficial which has in reality deep connections. In such cases a good plan is to put the sterno-mastoid into action by asking the patient to turn the head to the opposite side, when it will be seen that the glands are projecting into the triangle from beneath the anterior edge of the muscle.

TREATMENT.

It is not the purpose of this lecture to deal with the general medical treatment, but some reference must be made to local applications occasionally used before operation is recommended. First, as regards the poultice. This is applied with different objects in view—some, indeed, diametrically opposed to each other. It is employed with the idea of allaying pain, and there can be no doubt as to its frequent efficacy in this respect, but pain is rarely a prominent feature of tuberculous lymph glands; indeed, it is seldom present. Then, again, a poultice is sometimes used with the idea that it will do either of two things: either it will cause absorption of the hyperplasia producing the swelling, or else it will hasten the occurrence and completeness of softening. There is certainly no proof that moist heat can do either, while on the contrary prolonged poulticing may unquestionably do harm by rendering the skin soft and sodden and thereby militate against good healing after operation. Fortunately in this disease the use of this homely remedy is on the wane, more especially in sinus formation, where, besides softening of the skin, a considerable area of eczema may be induced. Iodine also is another remedy used locally in the treatment of enlarged glands, and here, also, it is very doubtful whether any good result is got by its application to glands which have really become tubercular. When one hears of such local applications having reduced the size or caused the disappearance of swollen glands, it seems very probable that in this instance one has to deal with glands which are not tubercular at all, but which have become inflamed from some irritation in the area drained by them, and that the decrease in size is due to the subsidence of the irritation and not to the applications. The less these tubercular lymph glands are irritated by local applications the better. If anything is used it should take the form of some simple, comfortable splint which will both protect the glands and steady the head.

The ideal surgical treatment is complete excision, which should be carried out whenever possible. In order to get the best results both from a cosmetic point of view as well as from the point of view of eradication of the disease, the operation should be performed before suppuration has occurred, and certainly before it has extended beyond the capsules of the glands, or caused sinus formation. It should also be understood that periadenitis with its consequent matting adds materially to the difficulty of the operation, and indeed may render dissection impossible. The diagrams which are before you show the lines of incision for clearing out glandular enlargement in the various regions, and when the incisions are placed as they now are along some of the natural folds of the neck, the cosmetic result is exceedingly good. The operation is seldom one that can be performed quickly, for the deeper glands in the anterior triangle are invariably in close contact with the sheath of the internal jugular vein, and indeed often also adhere to it. To clear this area requires patient and careful dissection in order to avoid wounding or tearing the vein. When the glands are adherent to the sheath, the best and the safest way is to remove the adjacent part of the vein with the glands, a procedure that can be carried out with impunity. A structure which gets in the way and requires to be avoided is the spinal accessory nerve, which may lie on or run through the centre of the mass, but is not difficult to identify and can be lifted aside or dissected out.

While complete dissection is the ideal procedure, it must not be understood that it can always be done, and that scraping has no place in the treatment of this affection. The spoon may have to be employed in conjunction with complete removal by dissection or by itself. When there is a subcutaneous abscess, or when a softened gland bursts during removal, then the spoon is indispensable for getting rid of the softened material, after which dissection of the remaining glands is proceeded with. Then, again, when sinuses

have formed, these must be scraped out and disinfected before removal of the glands is undertaken. Scraping alone has to be adopted where there is extensive glandular invasion and matting, with here and there softening areas. It must be borne in mind, however, that one occasionally comes across cases belonging to this class where the scraping so causes the periadenitis to subside that subsequent complete removal becomes possible. There is one condition where you may be tempted to rely entirely on the spoon, and that is where apparently one gland alone is involved and has undergone softening. It cannot be said that this does not occur, but my experience is that usually in close relation with the softened gland, often behind it, are one or two smaller ones which are not detectable by palpation, but which must be shelled out after the softening one is dealt with, or else the patient comes back again in a few weeks with a recurrence of his disease in the same place. Then it should be remembered that a subcutaneous abscess frequently communicates through a small opening in the deep fascia with a cheesy mass lying below, and this also, as well as the more superficial pus, must be cleared away if good and rapid healing is to ensue. When the spoon is used, therefore, it must be employed very thoroughly, and the scraping should be vigorous, so as to ensure the clearing away not merely of the parts of the gland which have liquefied, but the solid parts as well; and in order to ascertain whether that has been accomplished or not, there is nothing better than the finger. If the capsule of the gland has been quite emptied, then it feels quite smooth; whereas if some of the glandular material still adheres, it is detected at once by touch as a roughening on the otherwise smooth surface. After a scraping operation, an excellent plan is to apply some pure liquid carbolic acid to the cavity, and then, in many instances, stitches can be employed and good healing result. Broken-down tubercular material, unless infected, is not septic like the pus of an acute abscess, and if it is all got rid of, healing by first intention is to be expected.

Drainage should be employed after operations on the neck, even in aseptic cases, more frequently than in other regions, as it is impossible to apply sufficient pressure by dressings and bandages to arrest the post-operative oozing, which, unless drained away, accumulates and gives rise to subsequent bother, or may even favour the occurrence of sepsis.

Such, then, is the treatment of tuberculous lymph glands, but even in complete dissection uniform success must not be looked for. Now and again a case dealt with apparently in the most thorough and satisfactory manner comes back again with a recurrence, and it is disappointing to have to tell the patient that another operation is necessary. Such recurrences are seldom serious, and the patient can be reassured by the fact that his second operation will not be so extensive an undertaking as the previous one.

THE FUTURE PROSPECTS OF THE MEDICAL PROFESSION. (a)

By Sir LAMBERT H. ORMSBY, M.D., F.R.C.S.,

Senior Surgeon to the Hospital, and Past-President of the Royal College of Surgeons of Ireland.

At the commencement of his address Sir Lambert Ormsby dealt at length with the past history of the Hospital, and the antiseptic theory of the treatment of wounds. He then continued:—

I now come to the second part of my address—

The Future Prospects of Your Profession.—You will ask me what are your future prospects. In answer I may mention the Navy, the Army, the Indian Medical Service, foreign appointments, ship surgeoncies, Irish Poor Law Medical Service, and lastly, private practice. Of these, I fear I will only have time to make a brief allusion to two. Some years ago I spoke at length of the favoured conditions of the home Army Medical Service as a career, and I am still in favour of this service, notwithstanding there are yet a few grievances to be remedied which I will now mention.

Last June there appeared in the London *Times* two important letters, one from Mr. St. John Brodrick, and this was followed by another from the pen of Sir Frederick Treves, Bart. From the lessons we learned in the South African campaign about the enormous number of men who died from disease compared with the fatalities from shot and shell, these letters should be read, marked, learned, and inwardly digested by everyone having the interest of the British soldier at heart, and if the Army Medical Department is to be further reformed the sooner it copies the wonderful organisation in every detail of our Japanese allies the better. Prevention, we are told, is always better than cure, but prevention of a disease in an army in the field is a matter of incalculable importance alike from the point of view of humanity, of duty, of efficiency, and of economy. In South Africa the deaths from wounds were 42 per thousand, while those from disease were 69 per thousand. The admissions to hospital were 34 per thousand from wounds and 746 per thousand from disease.

The *Times* says: "Let the public ponder the meaning of these enormous disease figures, and consider the gigantic waste of money they imply, to say nothing of the misery and permanent impairment of health suffered by large numbers of those who recovered."

Mr. Brodrick declares that the regulations of the British Service as to the prevention of disease remain substantially what they were a hundred years ago. Not so with the Japanese, who have done in ten years what we have not done in a century. Japan, in the war of 1894-5, had nearly seven sick for one wounded, and twelve men died of disease for one who died of wounds. But what do we find in their recent campaign with Russia, ten years later. They had very little more than one death from disease for every three from wounds.

We are told that the British "Tommy" will not respond to discipline the way the Japanese "Tommy" will, and we are told that during the Russo-Japanese campaign a whole column of men had marched for many miles in a hot parching sun, and the men literally dying with thirst (the contents of their water bottles having been long since exhausted); so good was the discipline in that army that coming to a large canal of water which was marked "contaminated" the order was given that they were not to drink a drop of this water, not a single man of the column fell out of the ranks or disobeyed the order.

What would the British soldier have done under the circumstances. I fear he would have said "my parching thirst has no law; I must drink, even if I am shot for it, or die from disease."

I wonder do the British public know that the present Director-General of the Army Medical Department is only a subordinate, and yet he is the responsible head of the health and well-being of every officer and soldier in the British Army! Could anything be more ridiculous and grotesque than that the so-called *head*, at present, of the sanitary and hygienic department of the Army, is the Adjutant-General—an officer probably absolutely ignorant of medical science in every respect. This officer is again under the control of a Secretary of State for War, who may not only be ignorant of medical science, but who may be one of a large class common even among leading statesmen, who think "doctors" should only be seen and not heard, and who scorn science in general, and distrust medical science in particular. This, however, does not apply to the present distinguished War Minister, Mr. Haldane, who, I am informed, is a most enlightened statesman, and one who is most anxious to improve every department of the Army. For two years the Director-General had direct access to the Secretary of State, and was present at the Army Council, with great advantage to the Army. The Esher Committee placed him again under the Adjutant-General, who happened to be his junior in rank. How can a man without special and technical knowledge properly represent a scientific department? If the cry for efficiency has any real meaning at all, the present Government of Progress, assisted by Mr.

(a) Introductory Address to the Winter Session in the Meath Hospital, 1906.

Haldane, ought to speedily place the present Director-General, Sir Alfred Keogh, K.C.B., an Irishman of marked ability and prudence, and a sanitarian of the first rank, at the head of his department, and also give him a seat on the Army Council, and invest him with such authority and responsibility as shall anticipate any catastrophe in a future war, and in some way endeavour to do away with the defects of military organisation which led to such appalling losses from preventable disease in the South African campaign—losses which, as Sir Frederick Treves suggests, should weigh heavily on the consciences of the British people.

Such diseases as dysentery and enteric fever should have been to a large extent prevented if the advice of the Army Medical Sanitary Officer had been taken.

There is another matter I wish to allude to, and which has led to much criticism and well-grounded discontent among the profession, which is—Why should the same Civil Members of the Medical Advisory Board be re-elected over and over again? Why should they not serve for a specified term and then not be eligible for re-election? Surely there are many other leading physicians and surgeons in the three countries quite as competent to take a seat on this board, and give the Department the benefit of their varied experience and advice.

The status and position of the army surgeon is now well defined, and it is a military service which any gentleman should be proud to serve in. I therefore have no hesitation in advising all those having a taste for military life to enter the R.A.M.C. It is at present undoubtedly a splendid service, and offers great advantages to the young doctor of culture and social position joining its ranks. The service also affords the medical officer an opportunity of seeing life and the world in some of its best aspects, and foreign service has many and varied attractions in our widely extended empire, and at the same time confers on the recipient a social status not easily attained so soon in civil life.

Only the other day one of my pupils, who is just qualified, met me in the hospital, and I asked him what he was going to do. He answered, "I intend, sir, to have a try for the Navy." My answer to him was, "Don't enter the service at present."

Three years ago in one of my Presidential addresses at the Royal College of Surgeons, I drew attention very strongly to the grievances of the Naval Medical Service as they then existed. I deeply regret the grievances and defects I enumerated at that time have not, as I sincerely hoped, been remedied, and in justice to our medical brethren in that service I must return to the subject again. They, of course, are precluded by the King's Regulations to mention or even hint at their well-grounded grievances while in the service. I shall touch on the points I spoke of on a former occasion.

1. *Promotion.*—This question since I last addressed myself to the subject has been satisfactorily settled, though as must be expected rank for rank the executive is considerable younger than the medical officer.

2. *Foreign Service.*—There is room still for considerable reform in this respect; at present there is no roster nor any method in the manner in which appointments are made, certain favoured officers going from one shore appointment to another, or, what is equally bad, remaining indefinitely in shore appointments. Many of these appointments are made, as a rule, not for conspicuous ability, but for conspicuous influence.

Treatment of this sort disheartens those who have, as a result of the system, an undue proportion of service afloat. It does not tend to efficiency, as instead of having, say, twelve men equally capable of doing certain work, at present only one has an opportunity afforded him of doing it. Too much service afloat to men who are keen on their work is most disheartening. The men who like the service afloat are generally those who take no great interest in their medical work. If it were known that service afloat and service ashore were fairly and equitably regulated there would be little or no discontent on this score. At present if a Naval Medical Officer gets through a commission afloat satisfactorily he often finds that instead of a hospital he gets another ship, or else he is told he can go on half-pay.

3. *Compulsory Half-Pay* is to be regretted, but it is difficult to see how it can be avoided if there are more officers than appointments, unless it be by putting unemployed officers through hospital courses or study leave.

4. *Control of the Sick Berth Staff.*—This is a very important matter, and should be remedied without delay. The control of the sick berth staff on shore should be entirely in the hands of the P.M.O., who should have precisely the same power when serving in a Naval Medical Establishment on shore as is enjoyed by his military confrères in the Royal Army Medical Corps.

The P.M. officers of the Royal Naval Hospitals at present have no power to deal with breaches of discipline on the part of the sick-berth staff that serves under them, whether ashore or afloat. An Inspector-General of Hospitals and Fleets ranking with a Rear-Admiral or Major-General in the Army, before he can get a man punished, has to report him to the Executive Officer at the local depôt, and much time is wasted in making out written reports in connection with the case, and in sending the offender and witnesses for a distance, which in the case of Haslar is over a mile from the hospital.

The P.M.O. of a naval hospital should have power to award minor punishments in hospitals and sick quarters. It is ridiculous and humiliating to the profession that a senior medical officer cannot legally stop leave, award extra duty, or stop pay for misconduct among the staff of a hospital or sick berth of which he is the head, more especially when we come to consider that the punishment has often to be awarded for misconduct and neglects which took place a considerable time previously, owing to delays, of which only a naval medical officer can appreciate the significance. It is no wonder, under existing circumstances, that so many irregularities occur in large naval hospitals. It is most humiliating that a naval medical officer of distinguished rank may at any moment have to buckle on his sword, leave his ward duties, and go to the depôt to give evidence against a careless, disobedient, or drunken sick-berth attendant, the punishment of whom could easily have been awarded by the Inspector-General if he had the legal power on the spot when the crime was committed. The Executive Branch of the Royal Navy is a closely guarded "trades union," exceeding jealous of its privileges and prerogatives, both official and social. The Executive Board dreads the loss of these privileges and prerogatives, and is loth to sanction any power being given to anyone outside it. However, public opinion must, and will sooner or later, throw a little wholesome light into these matters.

5. *Medical Guard.*—It is the recognised custom in the present day when two or more ships are in harbour together for them to take in turn to keep "medical guard," and the ship keeping medical guard flies a special flag for the purpose. The Medical Guard has to remain on board, and is always available in case a doctor is required in any emergency in any ship of the fleet. This excellent system has not as yet been embodied in the King's Regulations, and the result is that some narrow-minded captains who cannot resist the temptation of showing their authority still insist on always having one of the two medical officers belonging to the ship on board, although there may be nothing going on in the ship that the medical officer of the guard (close alongside and capable of being on board within five minutes of the signal being made) could not attend to. The result of this is that the Fleet-Surgeon or Staff-Surgeon of a big battleship of this nature may find himself worse off than a Junior-Surgeon of a gunboat. Another captain will insist on both the Fleet-Surgeon and Surgeon being on board when his ship is medical guard. In other words, the Fleet-Surgeon, ranking with a Lieutenant-Colonel in R.A.M.C., is made to do the work of a surgeon ranking as a captain in the Army.

All this red tape is extremely galling to the medical branch of the Navy, more especially as no means of

redress can be obtained, for if the Fleet-Surgeon protests he is referred by the Captain to the Article in the King's Regulations saying that he must obey all orders he may receive from his Commanding Officer.

It should be clearly laid down in the King's Regulations that Medical Guard is to be recognised by the Captains and Commanding Officers of all ships, thus putting it beyond the capricious exercise of executive authority.

6. *Medical Surveys.*—To be an Inspector-General is the ambition of most Naval doctors, and it is disheartening and humiliating in the extreme to see these officers, ranking as they do with Major-Generals, forced to sit at Medical Surveys which are held for purely medical purposes under the presidency of a Captain or Commander of the Executive Branch. This is not only an absurdity and an indignity to the whole medical profession, but it is a direct cause of inefficiency, for the Executive Officer can of his own mere motion overrule the decision of all his medical colleagues on matters as to which he is incompetent to form a judgment. Such a condition of mistrust is lamentable, and is injurious not only to the Naval Medical Service but to the whole profession, for these Executive Officers, on retirement as Admirals, etc., carry with them into civil life the same wretched opinion of the status of the medical man as they have seen in the Navy. The matter is becoming one of national importance, and calls urgently for reform, and we, civil practitioners and hospital teachers, with all the weight of our influence, are bound to speak, write, and agitate in a forcible way, by argument and common sense, to remove the grievances and hardships which our naval brethren suffer from. For, as I have already said, by the King's Regulations, the naval medical officer is precluded from publicly ever making known his troubles and injustices.

In the Army the medical officers not only preside over their own Medical Boards, but sit as president, if senior, over all junior combatant officers, on all classes of boards.

7. *Courts Martial.*—When a medical officer is tried by court-martial for any offence, professional or otherwise, his judges are entirely seamen. It is the general desire, and it is only right, that some of the members constituting the court on such occasions should be medical officers of high rank.

8. *Salutes.*—It is very painful to see the neglect shown to naval medical officers as to salutes. Junior officials constantly pass them by without saluting them. This breaks down self-respect and the respect of the men. A Fleet-Surgeon is not entitled to "laying on oars" or to "letting fly sheet," as is the commander who may be years his junior. In the Army a medical officer of General's rank is entitled to the "turning out of the guard" like any other General, but an Inspector-General of Hospitals and Fleets going on board a warship is not so saluted. Why? Because, as the executive officers say, "he is only a doctor."

9. *Boats.*—In the matter of boats in harbour a senior medical officer has much to put up with. The Captain and Commander each have their own six-oared boats, which are at their own disposal at any and all times, yet senior officers like Engineer Commanders, Fleet-Surgeons, Fleet-Paymasters, or Naval Instructors of over fifteen years' seniority, all of whom rank with Commanders, must put up with the same boats at the same times as the youngest midshipman or most junior warrant officer.

In some ships the practice has of late obtained of putting one boat at the disposal of all officers of Commander's rank to take them ashore and bring them on board at such times as are mutually convenient. This practice should easily be carried out in all ships if it were generally recognised. At times it would be inconvenient, but the good sense and good taste possessed by the majority of senior medical officers would tell them when to waive their claims, thereby enhancing rather than lowering their dignity.

10. *Honours to Naval Medical Officers.*—The way in which the naval medical officers have been persistently ignored in the "Honours List" is proverbial. Fancy the Director-General and head of a department of over five hundred naval medical officers, a man who is responsible for the organisation of a body of surgeons for the whole British Navy, to be still allowed to remain without any recognition whatever, civil or military. In fact, there is not a single K.C.B. in the whole department on the active list, and only one C.B. and one M.V.O. I am aware on the retired list, among the Honorary Physicians and Surgeons to the King, there are a few titles given to these officers, but they are very few when compared with the officers of the R.A.M.C.

11. *Cabins.*—This matter, which affects the comfort of senior medical officers so much, has ostensibly been settled by the Admiralty, *vide* King's Regulations, 1906, Articles 836-837, pp. 298 and 299. In the former (paragraph 2) it says—"Special cabins are appropriated for the Executive Officer (this means the second in command), the Navigating Officer, the Chaplain, the Medical Officer, the Accountant Officer, and the Engineer Officer, the particular duties of the officer guiding the selection, and in ships fitted as flagships for the Secretary and the Flag-Lieutenant. A cabin will also be appropriated to the Second Engineer Officer, the position being fixed as near the engine-room as is convenient and practicable. The appropriation of these cabins is not to be altered without Admiralty sanction."

Paragraph 4, same article, states—"Officers will be allowed a cabin in the following order of priority:—

(*a*) Watch-keeping lieutenants in the complement.

(*b*) Engineer Lieutenants in the complement who keep watch at sea.

(*c*) Other wardroom officers not keeping watch in the order of their relative seniority.

"The Subaltern of Marines is always to have a cabin.

"Officers who have been allowed numbered cabins should be permitted to choose their particular cabins in the order of their relative seniority."

Now, one would have supposed that the Article (837, par 2) would have settled the question in a satisfactory manner. But hear what nearly always happens. When a ship is being prepared for commissioning she has a Navigating Officer and one or more Engineers appointed to her. These officers have an opportunity, therefore, of selecting their own cabins first, so that on commissioning it is found that "tallies," Navigating Officer, Engineer Commanding, Engineer Lieutenant, are over their respective doors, and these cabins are secured to them irrespective of the fact that the medical officer may be years senior to them, and these officers have to put up with whatever indifferent cabins it has pleased some minor dockyard official to place their "tallies" over.

In many instances the sewer pipe from the upper deck passes through the Fleet-Surgeon's cabin, and in other instances coal shutes and other abominations pass through it. If corroboration of these facts be desired an inspection of the nine ships of the Majestic class and the eight ships of the Royal Sovereign class will prove their truth.

I have heard in a ship in one of the fleets fitted as a flagship, but not carrying an Admiral (I believe there are several), the captain has ignored Article 837, par. 2, and insisted on the Fleet Surgeon occupying cabin labelled "Fleet-Surgeon," situated next the ward-room pantry, where he is not only annoyed by the constant chatter and noise made by the ward-room servants, but also in warm weather subjected to the annoyance of an invasion of cockroaches, which swarm wherever food is prepared.

Those captains who insist on their officers occupying these cabins appropriated for them invariably occupy those allotted to the Admiral, and turn their own cabins over to the second in command. The majority of ships nowadays are fitted as flagships, so that, except when the flag of an Admiral is actually flown on a ship, the question of selection of cabins invariably crops up, and unless the naval medical officer is a man with some force of character, grit, and determination, he is sure to go to the wall. As the executive

would imply by their action—anything is good enough for the "doctor."

12. *Social and Professional Respect.*—The Editor of the *British Medical Journal*, in a leading article, said—*inter alia*—"The refusal by certain commanding officers of the social recognition which is due to men who are at once officers and members of a learned profession is a subtler but not less galling grievance. This is a thing that can scarcely be dealt with by an Order in Council or Admiralty Instruction, for no authority can transform a naval officer who is a snob into a gentleman. Social recognition is largely a personal matter, and a naval medical officer who knows his work, and who, in his behaviour, shows a proper sense of the dignity of his profession, may, as a rule, hope to have little trouble on that score. The social difficulty, such as it is, would disappear of itself if medical officers were given the measure of authority in their own sphere which has been shown to be absolutely essential."

Lord Wolseley, in his "Soldiers' Pocket Book," sarcastically remarks that—"Medical advice is very valuable when it is asked for." Had he served in the Royal Navy he would have added—"and when it agrees with the opinion you have yourself already formed." Quite recently, and this is not exceptional, a man was reported to the officer of the watch on board a certain ship as being drunk. The officer of the watch examined the man, and pronounced him to be drunk. The man thereupon requested that he might be examined by the naval medical officer. The latter gave as his opinion that the man was sober, and capable of performing his duty, yet this man was kept under arrest, and when brought up for trial the medical officer's opinion was set on one side and the evidence of a sergeant of marines taken as of more value. When the medical officer afterwards protested against this treatment he was told that "we (Executive Officers) are the best judges of a man's fitness for duty. All we want to know is whether or not a man is ill." It would appear that a medical officer's opinion is only of value when it supports the opinion already formed by the prosecutor.

There are many other petty annoyances which irritate the naval medical officer, and to which time will not permit me to allude; but a little re-arrangement could easily remedy these matters without any loss of discipline or efficiency.

The present Director-General (Inspector-General Ellis) has done much to improve the service, and I know he has the interests of the service at heart, and is only too anxious to see his branch brought into efficiency and popularity. But I have no doubt that when he suggests improvements he is stopped by the Treasury, which will not sanction any improvement that costs additional money. The Government yearly expends millions on the building of warships intended to inflict death and suffering on our fellow-men if our interests should so demand. How much more, in the cause of humanity, should they be willing to spend a few thousands on a branch of the service whose mission it is to prevent or cure disease, and alleviate the suffering inflicted by shot and shell on our fighting men.

If the present Director-General fails to induce the Admiralty and the Treasury to amend these grievances by mild expostulation, these authorities will be forced in the long run to yield, because men will not go where discontent and limitation of status are maintained. In the end the Admiralty will have to follow the example of the Army, and at once accede to the suggestions of an energetic and independent civilian Advisory Board, constituted on the same lines as the R.A.M.C., but called in the Navy the Medical Consultative Board.

The R.A.M.C. now gets plenty of well-qualified candidates, but in the Naval Medical Service there is a deficiency of over fifty surgeons.

If many of these grievances are not removed shortly the remedy is simple and in your own hands. Avoid the Naval Medical Service for the present, which will compel the authorities, in order to get good men, to rectify the glaring defects by placing the naval medical officer in his proper position, and giving him, in all fairness, equal advantages socially and professionally with his less scientifically educated executive brother officer.

THE OUT-PATIENTS' ROOM.

FRENCH HOSPITAL AND DISPENSARY.

By J. P. BARONOFF, B.Sc., L.S.A.

GUMMA OF THE PENIS.—A man, æt. 48, who had syphilis fifteen years ago. He came with an ulcer on the penis, which at first was taken for a primary chancre. The glands in the groin were enlarged. The patient had had no connection lately; his wife died a short while ago. The man is a hairdresser. Mercury was given. A month afterwards a pustulous eruption came on the dorsum of both hands and also on the face. After a fortnight's treatment the patient was very much better. Mr. Baronoff said that the lesion on the penis was in his opinion a broken-down ulcerated gumma. This being a very rare lesion, he thought at first that the patient had been telling an untruth about having had no connection, though even had the man had connection he could only have considered the lesion a modified chancroid. The eruption on the hands was undoubtedly tertiary.

MITRAL INSUFFICIENCY.—A young woman, æt about 28, very thin and anæmic-looking, complained of weakness and a constant feeling of coldness; also of palpitation and dyspnœa. She came first about three months before, suffering from mitral insufficiency, with intermittence of the pulse. She had rheumatic fever two years ago, and during the course of the fever she suffered from endocarditis. Digitalis was administered with carbonate of ammonia. She improved greatly under this treatment. After three weeks the medicine was only continued irregularly. Since then she had taken a tonic. Mr. Baronoff laid stress on the importance of watching a patient carefully during a treatment by digitalis, which must not be continued for too long.

TERTIARY SYPHILIS.—A man, æt. about 59, presented himself with an ulceration at the angle of the mouth on the left side, which had been present for twelve months. He came up from the environs of London, and had been treated locally for some time, but without benefit. The ulceration was about the size of a bean, and was of a slate colour. After a little hesitation the patient acknowledged to have had syphilis fifteen, twenty-five, or thirty years ago. Mercury was ordered internally, and a little blue ointment for local application. In three weeks the ulceration had completely healed. Mr. Baronoff commented on the insidious appearance of these tertiary lesions, which he considered as very difficult to diagnose, especially in the present case, as there were no other symptoms whatever—no eruption, no glandular enlargement in the neck. The patient's history of syphilis was, however, very clear, but he had had four or five healthy children. The syphilis had been contracted before marriage. The sore was, Mr. Baronoff considered, an ordinary tertiary ulceration, not a gumma. The healing of the ulceration under the treatment confirmed the diagnosis.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

MULTIPLE NECROSES.—Mr. H. BETHAM ROBINSON operated on a girl, æt. 17, who had the following history:—In September, 1904, she had been admitted into the hospital with an abscess on the outer side of the right os calcis which had come suddenly only one week before; this was opened and only pus came out. Two weeks before the abscess appeared there had been a whitlow on the right thumb. She was

in the hospital two months, and when she left the abscess on the os calcis was healed. Three months after leaving the hospital there was some swelling on the upper part of the left arm; two months later there appeared in this region a "boil" and a piece of bone came away. The sinus so left had continued discharging up to the time of the present admission, but no more bone had come away. In August, 1906, a little red spot was noticed over the left side of the sternum, about the junction of the manubrium and the gladiolus; this spot had broken down, presenting an ulcer about the size of a half-crown, with overhanging skin edges at its outer margin. She was readmitted to the Hospital in September, and the following operation performed on the 14th: The sinus over the upper part of the humerus, which was near the anterior border of the deltoid and close to its anterior edge, was explored by making a vertical incision, splitting the muscle fibres and exposing the humerus. The humerus was locally thickened, and a director passed through the hole in the bone gave evidence of a definite sequestrum. The thickened bone over this was cut away with a gouge and a cavity exposed lined with granulations in which rested a well-marked spiculated sequestrum about two inches long. The place over the sternum was next explored; a bullet-probe passed under the undermined skin tracked outwards across the chest under the pectoralis major; this track was slit up by cutting the skin and splitting the muscular fibres in their length, but nothing more definite was found than a cavity at the right axillary margin filled with broken-down granulations between the second and third ribs. The wounds necessitated by this operation made good progress. Later another abscess was noticed on the right side of the spine filling the interval between the spine and the vertical border of the scapula. On opening this on October 2nd a large quantity of pus was set free, and its origin was traced to a round hole in the seventh rib just outside the margin of the erector spinæ. The hole in the rib, which had well-marked rounded edges, was about the size of a large pea, and the rib itself was broadened at this spot. A probe passed through the hole entered a cavity, to reach which the portion of the rib forming the lower part of the hole was removed. The cavity was filled with granulation tissue, and no further necrosed bone was found; in the pus from this abscess cavity a very small sequestrum was detected, and it was evident that it had come from the hole in the rib. Mr. Robinson said that the interest in the case lay in the diagnosis; it was a question as to whether the condition was due to syphilis, tubercle, or to some acute infective process. With regard to syphilis, there was no evidence of any hereditary taint, and the history of the development of the illness pointed strongly against it. With regard to tubercle, first appearances of the lesions present suggested such might be the cause, but the presence, on exploring the wound in the humerus, of a well-marked sequestrum was a point against it, as necrosis of the shaft of the long bones in tubercle was unusual; this opinion, Mr. Robinson considered, was supported by the history. The important point in the history was the development of the whitlow before the subsequent bone lesions; there seemed little doubt that the girl had had a mutiple staphylococcic infection secondary to the whitlow, which accounted for the foci of the disease of the bones with subsequent necrosis. A point brought out, he remarked, as occurs in many of these cases, was that one lesion particularly is often uppermost, as in this case the abscess of the os calcis, whereas other lesions keep considerably in the background, their existence only being brought to light afterwards by the slow appearance of an abscess, which, on opening up later, is found to be related to the necrosed bone. It was the slow development of these abscesses when the primary condition has not been sufficiently recognised that, he thought, caused many of these cases to be put down as tuberculous, and he would impress the fact that in multiple bone lesions somewhat chronic in nature in a young subject one has to consider the much greater probability of their being due to some acute infecton, such as the staphylococcus, rather than to tubercle.

The child is still in the hospital, and is making good progress.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD OCTOBER 12TH, 1906.

The President, Mr. CLUTTON, in the Chair.

AFTER a few words of welcome, the President began his address on the subject of

ADOLESCENT OR LATE RICKETS.

His first case was that of a man, æt. 21, when he came under observation nearly three years ago. His history showed that at the age of 12 he had had to wear supports for Genu Valgum, that osteotomy was done for both knees at the age of 16, and that the present curvature of lower limbs began to appear at the age of 19. The most striking part of his deformity was a double curvature at the knees producing a general resemblance to Genu Recurvature. Patient shown. The skiagram-photographs which were thrown upon the screen proved that the changes in the bones were of very long duration and had apparently commenced at the epiphysial lines. In the shafts of the long bones adjoining the epiphyses there was much less cortex than normal, and a large and translucent medulla. It was at this part that the curvature, which was the cause of the deformity, had taken place. The diagnosis of rickets was established by the changes that were seen at the wrists. The lower epiphyses of the radius and ulna were shown by means of X-rays to be in the active stage of rickets. Almost all the long bones showed changes at the ends of the diaphyses adjoining the epiphyses. Two other cases were shown and illustrated by means of skiagrams. They were æt. 12 and 14. The disease had arisen quite recently and was limited to the epiphyses. The contrast between the younger patients and the older one whose disease had been in existence for many years was the most interesting feature of the demonstration. Two *post-mortem* specimens were also shown, one from the Royal College of Surgeons, and one from the Hospital for Sick Children. A large number of skiagrams taken by Dr. Greg at St. Thomas's Hospital were also shown.

Mr. MUIRHEAD LITTLE described a similar case occurring in a girl, æt. 17. Infantilism was well marked. The changes in the bones were extremely typical of rickets.

Mr. CLEMENT LUCAS, after congratulating the society on the excellent address, said that the President had revived a discussion he had instituted in 1883. He referred to a paper then published in the *Lancet*, in which he had tried to establish a connection between late rickets and Moxon's intermittent albuminuria. He thought that the emotional state of puberty, with its uncontrolled passion, favoured the occurrence both of albuminuria and rickets.

Dr. PARKES WEBER suggested that cases of late rickets be investigated from the point of view of

albuminuria. It was interesting to recall that calcium salts cured most cases of cyclic albuminuria, as Wright has shown, whilst it has little or no influence on rickets.

The PRESIDENT, in reply to a question of Mr. Godlee's, said that he knew of no case that had occurred in a well-developed individual.

Mr. R. C. ELMSLIE, who showed two cases of the condition, said that though the occurrence of rickets in adolescence was established beyond doubt, its origin then was very doubtful. To prove that the child had never had rickets before was difficult for the following reasons. The history was very untrustworthy. In a large number of consecutive cases he had found distinct rickets in over 50 per cent. of the cases, whilst in only 1 per cent. of these was the existence of the condition known to the mother. The physical signs of rickets in these cases had nearly always disappeared by the age of 8, except for the puny development and head changes, particularly a curious high forehead. Now, these two features were invariably present in cases of adolescent rickets, suggesting thus an early origin.

Similar cases were also shown by Drs. G. A. Sutherland, J. A. Coutts, and R. Hutchison.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

INAUGURAL MEETING FOR THE SESSION, FRIDAY, OCTOBER 5TH, 1906.

THE President, DR. LEONARD MARK, delivered an address on

ART AND MEDICINE.

After thanking the Society for the honour which they had conferred upon him by electing him their President, he said that medicine had found a place in art since the earliest dawn of civilisation, and medical details have had to be represented in painting and sculpture just as well as details connected with other sciences or with sport, navigation, and the art of war.

If one studies the old masters, one sees that in some of their work great care is taken to hide details of a morbid nature or to touch them very lightly. Some examples of pictures from British galleries and art museums were shown by lantern slides to illustrate the subject. One of the most important was Raphael's famous cartoon at the South Kensington Museum, representing St. Peter curing the lame man at the gate of the Temple. Here it was shown how the artist had grouped his subjects so that a shadow from a column was cast over the deformed legs of the cripple.

Some facts concerning St. Roch and St. Sebastian in connection with the plague in the Middle Ages, and their important place in art were dwelt upon. Van Dyck's fine picture at Windsor Castle of St. Martin cutting off a portion of his cloak to give to a leper was described, with an account of the leper's appearance.

The subject of history came in, and the morbid peculiarities of some of our sovereigns which have been recorded in art were dwelt upon—Edward the Confessor, who was an Albino; Richard III., the hunchback; Edward VI., the boy king who died of consumption; and Mary I., whose appearance in some of her pictures is that occasionally seen in sufferers from ovarian disease.

In the part dealing with sculpture and carving, a curious ivory statuette of a dwarf with Pott's disease, to be seen at the British Museum, was mentioned.

A photograph was shown on the screen of the doctor's signboard of the seventeenth century, now at the Royal College of Surgeons, with some quaint groups of carved figures representing the doctor at his daily work.

The subject of death as represented in painting had an important place in the paper.

Reference was also made to a few modern pictures, such as "The Death of Chatterton," by Henry Wallis, Millais' "Ophelia," floating in the water, and, last of all Luke Fildes' "The Doctor." In this picture morbid details are conspicuous by their absence, and the whole interest of the picture is expressed in the distress in the face of the father, and the mother's attitude of despair, and the kindly look of the doctor, which is full of concern.

FRANCE.

Paris, Oct. 15th, 1906.

COXALGIA.

THE commencement of coxalgia is insidious. There is a certain amount of claudication, and pathological anatomy teaches us that at this moment there is an increase in volume and a certain vascularity of the fringes of the synovia, with an increase in the serosity. Still more, and what is unfortunately more serious, says Professor Kimisson, there exist lesions of the cotyloid cavity and of the head of the femur.

In two-thirds of the cases the tubercles end in suppuration.

The malady terminates in one of three ways—suppuration, ankylosis, and preservation of the movements.

Suppuration is revealed by an increase in the pain and high evening temperature. Hence the necessity of changing frequently the apparatus, for the issue of the pus is effected either by the classical manner, femoral abscess, gluteal abscess, or pelvic abscess, or else in more unusual positions: iliac fossa, Scarpa's triangle, great trochanter. Reabsorption may take place, but it is rare. Once the abscess opened, septicæmic fever sets in, endangering the outlook.

M. Kimisson fixes at three years the period necessary to obtain a cure, as in Pott's disease.

The treatment consists in immobilising the limb in a plaster apparatus. If at the end of a year and a half there is no pain provoked by movements or pressure, if there is no fever nor abscess, the case might be considered as cured, and attempts at walking might be allowed.

If an abscess is formed it should not be opened with the bistoury, but the pus drawn off with an aspirator and a solution of ether and iodoform injected. Where the abscesses are formed at an early date the prognosis is grave, but those appearing after two or four years heal very easily.

Forced extension should not be used, but continued extension by means of a weight of 8 or 10 lbs. for a child of 8 or 10 years. Surgical operations have not given good results.

Dr. Privat, of Berck-sur-Mer, considers it of the highest importance that the practitioner should detect coxalgia in its incipient stage, for which purpose he enumerates certain signs and symptoms that should attract the attention of the medical attendant.

Each time that a child is brought to the consulting-room presenting one of the three following symptoms: (1) the child suddenly awakes at night complaining of pain either in the hip or in the knee; (2) the child gets tired very quickly—after a walk or long standing he complains of pain either in the hip or the knee, which, however, disappears after a rest; (3) the child, hardened to pain, does not complain, but the parents have remarked that he limps a little. Such are the first symptoms of the malady, and are of value, but the diagnosis must be based on three other characteristic symptoms which are the natural sequence of the preceding: (a) limitation of movements of abduction of the hip; (b) pain on pressure on the head of the femur; (c) lengthening of the limb. To discover the first symptom, the healthy limb should be examined carefully in all its movements, the leg flexed on the thigh, the thigh on the pelvis, and while the left hand presses on the anterior and superior iliac spine, th

right hand seizes the knee and abducts the thigh, so as to make it touch the surface of the table, and the experiment succeeds without any trouble. Not so in the diseased side. The movement is arrested, the adductor muscles become like cords on the inside of the thigh, while if the knee goes down under the pressure of the hand, the iliac joint goes up. To find out if the parts are painful it is not necessary to hit the heel of the patient, as is generally practised; it is far better to make direct pressure over the head of the femur.

To arrive at this result, the practitioner will act as in the case of appendicitis, where the finger is pressed down over the MacBurney point.

The point which corresponds anatomically to the head of the femur is situated perpendicularly to Poupart's ligament, about its middle. It suffices to draw an imaginary line between the iliac spine and that of the pubis, and take the middle of that line. This point is situated at a quarter of an inch external to the femoral artery; or, more simply, the head of the femur is to be found in the angle formed by the femoral artery and the crural arch within half an inch of the apex of this angle and close to the interior border constituted by the artery. The experiment should be first made on the healthy side. The index is pressed gently on the fixed point, and the same operation done on the other side. If no pain is produced, the operation should be repeated, and for several times if needs be, but each time the pressure should be increased. With a little perseverance the pain will be provoked on the suspected side. If the two signs, limitation of abduction and sensibility of the head of the femur, are present, the case may be considered as being arthritis of the hip; if the third, or lengthening of the diseased limb, be also discovered, the diagnosis should be that of coxo-femoral tuberculosis.

If, concludes Dr. Privat, pain is absent a doubt might be entertained, but in any case the child should be undressed and the vertebral column, as well as the knee and the foot, carefully examined for possible Pott's disease, a white swelling, or some general affection.

GERMANY.

Berlin, Oct. 14th, 1906.

The External Application of Alcohol in Inflammations.

This subject has been many times brought before the profession, but the systematic use of alcohol in inflammations has never seemed to catch on. A recent paper on the subject in the *Therap. Monatsch.* for September, by Dr. Alexander Raphael, of Mitau, brings it once more forward.

Alcohol compresses of wadding in lint were applied and covered with an impermeable waterproof layer and kept undisturbed as long as they were moist. To remoisten them the upper waterproof layer was simply lifted up and the spirit poured again on to the compress. A strength of 90 to 95 per cent. of alcohol was made use of. Eight cases of appendicitis were treated in this way; one case terminated fatally on the fifth day, the others recovered. The compresses were kept on from two to six weeks. They were only removed when the skin became sore and blisters formed. After powdering with salicylate of bismuth and a day's rest, the dressing was recommenced and again well borne. In one case of tuberculosis of the mesenteric and pelvic glands in a lady, æt. 40, the treatment was kept up practically for three months. One gland after another suppurated and burst into the bowels, as in the appendicitis cases. In all the cases the first thing noticed was that the pain ceased in a short time. The symptoms of toxine poisoning in the blood, headache, and sleeplessness got better. The objective results were improvement of the pulse and fall of temperature. The inflammatory exudation became firmer, it seemed more distinct from its surroundings; melting down of the centre followed without much pain. The fever subsided usually before the bursting of the abscess, whilst the pulse only slowed after this had taken place. Two of the appendicitis cases did well without any pus appearing in the stools.

In a case of suppurative parametritis after abortion in a patient æt. 28, the exudation became localised. At the operation of opening—incision parallel to Poupart's ligament and drainage through the vagina—the walls of the abscess cavity were seen well covered with firm granulations.

A case of mastitis that had been opened but would not heal up was brought to the writer, who treated it with tampons soaked in alcohol, when it healed up quickly. Cases of early mastitis frequently ended by resolution. Cases of tendovaginitis phlegmon, as well, generally ran a favourable course under spirit compresses. The compress was also used when the abscess was ripe for the knife. The wound was filled with iodoform gauze tampon, and alcohol then poured on so long as necrotic slough continued to show. In this way two things were achieved: first, the flabby granulations disappeared, the sloughs were also cast off more quickly, and were in many cases mummified by extraction of water

Some cases of scrofulous glandular swelling the size of a hen's egg in the neck and under the chin became visibly smaller under compression. The pain caused by the spirit on an open wound disappeared in the course of a few minutes. For some time he had treated all sorts of smaller wounds, bruises, and cuts by washing the surrounding parts with alcohol, suturing if necessary, then placing over the wound a compress of iodoform gauze soaked in alcohol, and fixed on. He has been much pleased with the results. Union generally took place by first intention, and he has never seen gangrene of the skin for a long time. A good effect was produced also in skin diseases, especially in children. Before any ointment was applied to the skin it was vigorously rubbed with a pledget of lint soaked in alcohol. The ointment acted much more energetically and penetrated into the pores better. In eczema a 10 per cent. solution of epicarine acted much better than a lanoline ointment of like strength. Herpes zoster and erysipelas ran a favourable course. A case of vascular nævus at the root of the nose healed up under the alcohol compress, leaving a firm white cicatrix at the spot. Some cases of commencing inflammation from injury recovered in the course of twelve days under alcoholic compresses.

Dr. Raphael has also syringed out the uterus with a 45 to 50 per cent. solution of alcohol in retention of membrane and pieces of placenta, and also in case of puerperal fever. He first syringed out both vagina and uterus with camomile tea and then allowed 200 to 300 grm. of a 40 to 60 per cent. solution of alcohol to run slowly through. If this strength was well borne, as it almost always was, he proceeded to more concentrated solutions up to 90 per cent. Whilst this was being done the external part had to be protected by vaseline. Both in the uterus and vagina the alcohol was only felt as an agreeable warmth. Finally a tampon of alcohol was placed in the vagina. All cases of this kind also had alcohol compresses over the abdomen. In all cases of retention of membrane the fever sank rapidly, and the shreds were soon expelled. The only case of puerperal fever ended in recovery after some weeks of illness. Whether recovery was due to the alcoholic treatment would be difficult to say. Two cases of perforative peritonitis in connection with typhoid and treated with alcohol compresses are also described. Both terminated favourably, and in both the favourable termination was attributed to the alcoholic dressings.

AUSTRIA.

Vienna, Oct. 14th, 1906.

Cysticercosis Cerebri.

Chiari related the history of a man, æt. 45, at the Prague meeting, who six years ago commenced having epileptiform attacks, which gradually produced

a form of dementia ending in death after an apoplectiform attack. The cysticerci were found distributed through the brain substance in different stages of growth. The vesicles were found in groups extending along the spinal cord, where two were found as far down as the cauda equina. Although cysticerci cellulosæ is common enough in Prague as an accident from impregnated food, he has only seen other two cases that led to death.

PROPHYLAXIS OF TUBERCULOSIS.

Hueppe next read an exhaustive paper on tuberculosis and how to prevent attack. He said it has often been repeated that it was a difficult problem to solve, as we could not definitely fix the path by which the virus was introduced. According to the oldest record we have—the Bible—the mode of infection is by contagion. Pettenkofer held the opinion that locality was the most potent factor. Cornets avowed that dust inhalation was the cause; Flügge maintained that the poison was conveyed by moisture; while Koch frightens us with the communion of animals; and lastly, Behring and Weleminsky tell us that the nature of our food is responsible for the whole destruction of life. In the prophylaxis of the disease four factors may be considered—viz., exposition, infection, disposition and invasion. With our obscure knowledge, exposure to risk should always be avoided. This prescription must be very limited, as we cannot under the present circumstances ostracise a fourth, at least, of the human race as unfit for society.

According to statistics, the nature of employment and surroundings have something to do with the mortality, and nurses are not without this danger. Those engaged in general work have a death-rate of 30 per cent., the Red Cross have 33 per cent., Diaconal have 52 per cent., while the Roman Catholic sisters have 66 per cent. It would seem, therefore, that one-half of the nurses and a third of the population, which have 24 per cent., are afflicted with this fatal disease. There is no doubt that the ascetic life of the Roman Catholic sisters has much to do with the attack, being drawn together in close rooms with poor food, where everything would favour transmission. It is to be noticed that different orders in this religion have higher death-rates, some of them even reaching 92 per cent. Care should therefore he exercised on the nursing personnel. Change and open air are always to be recommended to such patients, as sanatoria always give the best results; even here the more susceptible require to be educated in personal hygiene to make the prophylaxis more complete. Jaksch pleaded for more stringent regulations to prevent spitting in streets and public places, as the bacilli got mixed with the dust, which again was inhaled by the healthy. There was no doubt that infection could be conveyed by clothing in close rooms where the bacilli were transmitted to the healthy. Although Koch tells us that human and animal are different, it is certain that animal infection does much destruction. Taussig remarked that workshops seemed to have a heavy record in this respect, as the deaths occurred between sixteen and sixty.

MORBUS BASEDOWII.

Jaksch next presented a patient suffering from enlargement of the thyroid, for which he had tied the thyroid artery inferior, with the result that the entire bony structure became affected. As time advanced the long bone began to split and atrophy. The radius and ulna have recently broken symmetrically in both hands, and the arms are totally atrophied. The scapula is as thin as paper, the clavicle like a quill, and the diaphyses of the humeri separated. The patient is also suffering from an atrophied osteomalacia of the pelvis, while the bones of the lower limbs are similarly wasted. The whole was clearly demonstrated by the Rontgen rays. He considers Basedowii a disease closely allied with the nutrition of the bony structure, as Hornicke long ago pointed out.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

VICTORIA HOSPITAL FOR CONSUMPTION, EDINBURGH.—This hospital is to be enlarged by the addition of an administrative block and two pavilions containing twelve beds each. The latter are exact copies of the pavilions which were erected some years ago, and which have been found in every respect admirably adapted for the purpose for which they were designed. The principal feature of the new building is the patients' dining hall. Up to the present the offices of the hospital have been housed in the old mansion house, the pavilions being distributed through the grounds, and with the growth of the latter more extensive administrative and central buildings have been greatly needed.

EDINBURGH POST-GRADUATE CLASSES.—The post-graduate course which has just terminated has proved a success far surpassing the expectations of its promoters. Both in point of the numbers of graduates attending it, and on the enthusiasm with which the various teachers entered into the scheme, it has been carried through in a most satisfactory manner. The graduates who took part in it have almost unanimously expressed themselves as delighted with the way in which the classes were conducted, and there is now little doubt that this resuscitated course will be carried on steadily from year to year. The energetic secretary, Dr. Edwin Bramwell, deserves to be congratulated on the success which has attended his labour of love.

COTTAGE HOSPITALS AT MOFFAT AND CRIEFF.—During the past week cottage hospitals for non-infectious diseases have been opened at Moffat and Crieff. The Moffat Hospital, which was opened by Mr. William Younger, of Anchor Castle, is a one-storey building consisting of two large and one small private ward, with a surgery suitable for performing operations in. The hospital has been erected by means of a fund which came into existence in 1890, as a result of litigation between the working men of the town and the Working Men's Institute. The Crieff Hospital is much on the same plan. It was opened by Mrs. Whitelaw, of Strowan, who has taken an active part in promoting its erection. In both cases the architect was Mr. Maidman, Edinburgh.

EDINBURGH UNIVERSITY UNION.—The enlarged Union buildings are now completed, and will be opened on the 19th by the Lord Rector, the Right Hon. R. B. Haldane. Mr. A. J. Balfour, the Chancellor of the University, will preside. After the opening ceremony there is to be a reception, followed in the evening by a house dinner. The University Union was opened about seventeen years ago, and some idea of its popularity and success may be gathered from the fact that whereas the original buildings, which seemed spacious enough to the first members, cost some £16,000, the required accommodation provided by the recent extensions has cost nearly double that sum. The membership of the Union has greatly increased since 1897, when the Union Committee took the catering into their own hands, and now amounts to 1,200. The work of raising funds for the extension was begun at a meeting held in the MacEwan Hall in January, 1903, whereafter a site immediately to the west of the present building was secured. Owing to lack of funds the additions were proceeded with piecemeal, the first extension comprising a side room to the large hall, with additional lavatory and storage accommodation. Next the dining hall was enlarged, a new billiard-room taken in hand, and electric light installed. The third and most important addition is now finished, and includes library and reading-room, committee and writing rooms, and two fives courts. The new wing contains a spacious library with a gallery and eight bays, capable of containing 8,000 volumes. Adjacent to this is a general committee and writing room; while in the same section of the building there is a barber's saloon with bath-rooms and lavatories. The old library and committee rooms have been thrown into the entrance hall, which

was formerly somewhat cramped. On the upper stories of the new wing there is a large luncheon room, a new kitchen, and a large reading and writing room, which can also be used for functions for which the large hall is unsuitable. Up to the end of July the Union had raised about £8,000 of the £26,000 needed. Since then Sir Donald Currie and Mr. Andrew Carnegie have each promised £6,000 on condition that the balance of £6,000 be raised within a year.

GLASGOW.

The Late Dr. Finlayson.—A Personal Reminiscence.—Dr. James Finlayson, physician to the Western Infirmary, Glasgow, died suddenly at his residence on the 10th inst. He was in his sixty-sixth year, and appeared to be in his usual health, when he was struck down by cerebral hæmorrhage. Dr. Finlayson was born in Glasgow on the 22nd day of November, 1840. He graduated M.B. in 1867 with honours. Dr. Finlayson received the honorary degree of LL.D. of Glasgow University in 1899, for his eminence as a physician and his many valuable contributions to medical literature. He received his early training under Sir W. T. Gairdner, who might be said to have founded in Glasgow a school of philosophical physicians, of which Finlayson was a bright example. They were versed not only in the history of diseases, but nearly as much in the history of mankind. Although Lister had by this time pointed the way, in a practical fashion, of ascertaining the causes of diseases in the invisible fauna and flora surrounding the bodies of animals, little work was done by the Glasgow Philosophical School in following up Lister's brilliant ideas, which have been so fruitfully pursued in laboratories in London and the Continent. After the patient died we followed him to the post-mortem room, and there we saw the gross anatomical lesions which were supposed to be the cause of the disease the patient suffered from. At least, that was the idea given to students some twenty years ago. It must be said, however, that pathological anatomy was pursued with great avidity, and Drs. Joseph Coats and Lindsay Stevens' work can scarcely be forgotten. The painstaking way in which a case was overhauled, the elaborate life-histories elicited, the post-mortem records connecting the past life history of the individual with the anatomical changes in the organs, all this was calculated to make first-class clinicians, but not original investigators. I think it may be said with truth that there can be few schools of medicine with finer clinicians than the Glasgow school, and Dr. James Finlayson was one of its brightest ornaments. His "Clinical Manual" was the guide of many generations of students, as year after year fresh men came to the wards. But this work got superseded in later years, as the discovery, say, of the amœboid organism in the red discs of the blood is a more important matter than elaborate clinical diagnosis of ague. Dr. Finlayson was regarded by the profession and the public in the West of Scotland as a physician pre-eminent in diagnosis, one in whom every confidence could be placed. To his knowledge of medicine he added great learning, and was therefore a faithful disciple of Sir William Gairdner. It is said that his contributions to medical literature number about 150, and they range well nigh over the whole field of medicine. One of his more important works is an "Account of the Life and Works of Meister Peter Lowe, the Founder of the Faculty of Physicians and Surgeons of Glasgow." Dr. Finlayson was President of the Faculty from 1900-1903. He was a typical Scotchman, of quiet manner, cautious and careful in what he did, and possessed of great patience and perseverance. J. T. M.

District Medical Dispensaries in Glasgow.—At a public meeting convened on the 12th inst. to consider this question, Lord Provost Bellsland stated that the population of the district in which it was proposed to establish a medical dispensary was between 60,000 and 70,000, mostly of the working class. The sum of £3,000 was required, of which £670 had been subscribed. The dispensary would be similar to those in other districts, but special attention would be directed to the treatment of diseases of women and children, thus endeavouring to mitigate the terrible evil of infantile mortality. On the motion of Dr. Carswell, supported by Drs. Russell and Chalmers, it was agreed to establish the proposed dispensary in the Anderston district.

BELFAST.

Death of Mr. May, Rathfriland.—One of the oldest medical men in Ulster passed away last week, Dr. Joseph May, J.P., of Rathfriland, co. Down. He was born more than ninety years ago near Dromara, co. Down. He took the L.A.H. in Dublin in 1844, and the double qualification of the Edinburgh Colleges in 1860, and practised in Rathfriland till 1881, when he resigned the dispensary, and was succeeded by his nephew, Dr. James May Elliott, who still holds it. For the last twenty-five years he interested himself in his magisterial duties, and in the affairs of the Presbyterian Church, of which he was an ardent member.

The Typhoid Outbreak.—A special meeting of the Public Health Committee was held last week to consider what action should be taken in view of the results of investigations as to the cause of this outbreak. As was reported some weeks ago, the cases could be traced pretty clearly to a certain milk supply, and several cases of typhoid were found among the customers of this dairy outside the city. But on inspection and examination nothing whatever could be discovered wrong with the dairy, which seemed indeed to be almost a model one. No sickness was found on the farm, and the milk, water, and drains were all tested with negative results. On further inquiry it was found that a woman who was occasionally employed to milk had been ailing some months ago, apparently with pneumonia. A sample of her blood was obtained, and gave a marked positive reaction with Widal's test. The milk had now been "withdrawn from public sale," but till a few days ago, and for many days after it was suspected, it was still freely sold, the dairy proprietor acting on the advice of his solicitor that there was no case against him when the examination of the milk gave negative results. The facts have now become public property, and have raised a storm of indignation. Of course, the public attribute the delay in cutting off the suspected milk supply to the want of a properly qualified medical officer of health, and though no doubt there were legal and technical difficulties in the way, it is hard to believe that a capable and energetic medical officer would have sat quiet for two or three weeks, while some score of cases of typhoid were notified each week, all among the customers of one dairy!

The Health of the City.—The agitation against the recent appointment of an inexperienced man as medical officer of health proceeds vigorously. The Chief Secretary for Ireland has consented to receive a deputation from the Citizens' Association with regard to the matter, and it is intended to demand a Royal Commission to make full inquiry. To show the strength of feeling on the question, it is worth reporting that one gentleman has offered £100 towards a guarantee fund for any necessary expenses incurred in this movement, and has said that if expenses run into thousands he will give £500.

Failure to Notify.—Dr. D. C. Smiley was summoned last week for failure to notify a case of typhoid which had been under his care for nearly two months. There was no appearance for the defence, and the maximum fine of forty shillings was imposed.

Our Edinburgh correspondent informs us that Dr. Andrew Carnegie has bestowed on the University of St. Andrews a gift of £22,500. £10,000 of the sum is to be devoted to the extension of the University library, and the remainder to the Physics laboratory in University College, Dundee.

LETTERS TO THE EDITOR.

THE COMING ELECTION TO THE GENERAL MEDICAL COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall be glad if you will permit me to announce that Mr. J. Rutherford Morison, F.R.C.S., of Newcastle-on-Tyne, in response to many requests, has reconsidered his determination not to stand for election, and will now be a candidate. His address to the profession will be issued shortly.

I am, Sir, yours truly,
ALFRED COX,
Hon. Sec. to Election Committee.

Cotfield House, Gateshead, October 12th, 1906.

THE DECLINING BIRTH-RATE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I assure your correspondent "Obscure Practitioner" that I in no wise confound the British empire with the British nation. I am quite alive to the facts enumerated in his letter, except that I was not acquainted with the identical statement that "there is room for our surplus population for the next 500 years." It would seem to me that a calculation of this profundity, to ensure its accuracy, must require the combined intellects of mathematicians, statisticians, historians, and obstetric authorities. However, accepting such as literally true, I nevertheless apprehend that it is the duty of a State analogous to a parent towards children to make adequate provision for its offspring; hence, that the health of the British nation is of primary, and the vastness of our empire of secondary importance. Let us beware, therefore, pending these 500 years, that we do not in the meantime as a nation long ere that period has elapsed, and before the full development of a fantastic and phantom empire, come to grief in our own home or castle, if we convey to the world that the one idea of the principal function of the British nation is to produce healthy progeny for pastures elsewhere on the globe, and leave the decrepit to multiply within our own shores. Decadence or degeneration would result sooner or later in the disintegration of our entire empire. Nothing, as I have remarked previously, could more speedily effect this than extreme poverty and numerous offspring, without the necessary ways and means to rear them in a healthy moral and physical condition.

I am sorry I misunderstood the term "well-bred" as applied by your correspondent. I thought he used it in a conventional sense, supposing the upper stratum of a community would provide healthier stock than the lower. I called attention to a statement of great import in your correspondent's letter, viz., where he advances the proposition that the unhealthy are multiplying out of proportion to the healthy. I hold this to be a separate proposition to a declining birth-rate, because the one might take place independently of the other. For example, if the birth-rates were to rise, and at the same time a greater proportion of the unhealthy were to multiply, decadence would still go on, hence decadence and increasing birth-rate might co-exist. It is vaguely said of statistics that they may be made to prove anything. The true meaning of this is that different observers draw different inferences from the same statistics. Now, if these inferences are equally probable and somewhat contradictory, instead of proving "anything" they prove nothing.

I am, Sir, yours truly,
CLEMENT H. SERS.

Brighton, October 13th, 1906.

MEDICAL REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—One of the reasons why the doctors are suffering as they do is the fact that the public can go and get the article gratis—the real article, high quality for nothing at our hospitals. Naturally, what we can get for nothing we don't esteem very highly, and nowadays with all classes the question is what hospital to go to where the best can be got. The question that naturally arises is, Why do hospitals do this? What is their reason or object? The reason a business man would give is simply that "if he can get the doctors to work for nothing at hospitals, just see what we, the public generally gain by it. We can leave the ordinary doctors alone. They are not up to much, and we can do without them." The question the doctors are beginning to ask themselves is whether they may leave the public alone, or whether they are justified in opposing this system which is steadily ruining them.

Some may take the view that the hospitals may be left alone, as they feel sure they won't get money to carry on with; and probably the men who work at hospitals for nothing may find out that it doesn't pay. Of course, if hospitals don't work as advertisements that pay, that method of advertising will be dropped. So some think it best to leave hospitals alone, and do nothing to keep them. A good many are going from bad to worse, and as the poor are provided for out of rates and taxes, hospitals will die out, like many other of our old charity institutions. That's the view that some take. One of two things must happen. We may slowly degenerate and come to the state in which China has been now for many years, and the doctor may lapse into the blind huckster of charms with a dog and a stick to help him; or the public may have sense enough to see that they will suffer and go down to the miserable condition of an effete people. Would it not be best, sir, if this question is going to be handled by the doctors generally, that they let it clearly be understood they have one object in view, and that, before all others, namely, the good of this our country, and the people who live in it? I am, sir, yours truly,

CANTABRIGIENSIS.

OBITUARY.

JAMES HANCOCKE WATHEN, M.R.C.S.E., L.R.C.P.EDIN.

WE regret to hear of the death of Mr. Hancocke Wathen, on the 5th inst., at Stoke Bishop. The deceased gentleman, who was a native of Fishguard, in South Wales, had resided for many years in Bristol, where he practised as a surgeon. He was trained at University College and the Royal London Orthopædic Hospital, and took his degree of M.R.C.S.Eng. in 1865, and two years later the L.R.C.P.Edin. He was appointed assistant house-surgeon at the Bristol General Hospital. Subsequently he served as house-surgeon to the West London Hospital, and Orthopædic surgeon's assistant at University College Hospital. At a later date he practised in Clifton in conjunction with Dr. Steele, though the partnership was dissolved some years ago. For a long period up to 1901 he filled the position of Medical Officer to Clifton Wood Industrial School, and another institution with which he was associated was the Skin Dispensary. He also took an active part in the Volunteer movement, and he retired from the Gloucestershire Artillery Volunteers with the rank of Surgeon-Captain. It was in comparatively recent years that he became identified with civic affairs. Mr. Wathen, who married a daughter of the late Sir George Edwards, had not been in robust health for some time past, but he was well enough to be in the city a few days ago.

INSPECTOR-GENERAL E. R. H. POLLARD.

WE regret to record the death of Inspector-General E. R. H. Pollard, of the Royal Naval Hospital, Chatham. He had been a member of the medical department of the Navy for nearly thirty years. As surgeon on his Majesty's ship Boadicea he landed with the Naval Brigade during the Zulu War of 1879. He also served with the Royal Marines in Egypt in 1882, and was present at the Battle of Tel-el-Kebir. For these services he received the Zulu medal, and the Egyptian Medal and Clasp and the Khedive's Bronze Star.

SPECIAL ARTICLES.

THE LONDON MEDICAL EXHIBITION.

(Concluded.)

It is now possible to have Droitwich Baths at home, for Messrs. Weston and Westall put up the evaporated salt into bags so that for baths to be taken away from the town. Nestlé's Company, besides their well-known tinned milks and Milo Food, have just started a dairy in London, under the style of the Ideal Dairy Company. They were exhibiting the chief feature of this departure, namely, bottles of fresh milk which will be delivered at houses at the same rates as that usually supplied in cans. The stopper of each bottle is sealed with a disc when the milk is sent out, so that no contamination can occur in transit. A novel substitute for tea, coffee, and cocoa was on view. Under the name of Ovaltine, a combination of malt extract, fresh eggs, milk, and converted cocoa—to which is added Lecithin—is made up, and is surprisingly palatable and refreshing. Dr. Wander, of Berne, who has recently brought the preparation to this country, has also a Dry Crystallised Extract of Malt, which seems to present a useful form for administering this favourite remedy. Messrs. Seabury and Johnson's Thermogene and surgical dressings have a high reputation, and their ingenuity in finding ways of aiding the surgeon to preserve asepticity with the minimum trouble are endless. Even ligatures of all sorts of materials, and needles ready threaded with sutures, are supplied ready sterilised in separate boxes for each suture or ligature. Some of their new plasters are well worthy of trial. Dr. Theinhardt's Food Co., Ltd., have recently started business in England, and they have a variety of useful foods to offer prepared chiefly from Professor König's formulæ. They all seem to be of good nutritive value. Pumuline may not be known to everybody, but it is a pleasant essential oil, made by Messrs. Stern and Co., of Manchester, into soaps, ointments, and various lotions. Messrs. Parke, Davis and Co., as usual, are quite in the front of progressive pharmacy; indeed, they had a bewildering show of new and old friends. Their Typhoid Agglutometer, whereby any practitioner may do his own Widal's reaction at home, with nothing but what is supplied in the case, and without any skill in bacteriological technique, is an exceedingly ingenious apparatus. Among the publishers, Messrs. Baillière, Tindall, and Cox had a capital display of new books and new editions, their "University Series" especially meeting with widespread attention by the uniformly high level of success attained by each volume. It is difficult to say which of their deservedly popular manuals is the most esteemed. Messrs. W. B. Saunders had many of their American medical books on view, and Messrs. Cassell and Co., Messrs. Constable and Co., and the Oxford University Press all had a brave show of good books.

The invalid specialities of Messrs. Brand and Co. were old friends to most of the visitors, but one noted that the firm are well up to the requirements of the times, and that they now have a meat-juice of high grade, and various peptone preparations to suit all digestions. Of Bovril it is almost supererogatory to speak; everyone knows Bovril; but it may be news to some that Bovril lozenges, Bovril staminoids, and Invalid Bovril are prepared for various special purposes. Moreover, all kinds of concentrated forms of meat are sold by the firm for travellers, soldiers, and those who go exploring. Thomas Christy and Co. had an interesting stall. Glycothymoline greeted one with its usual fragrance, and Christy's surgical apron and dressings were there in their glory. There were numerous new compounds on view—Lysoform, a formaldehyde disinfectant, Alphozone, a harmless antiseptic, Adnephrin, Fluor-Rennin, a new drug containing fluorine, Antitussin, and many others testifying to the resource of the makers. Burgoyne, Burbidge and Co. were showing a variety of elegant preparations of emulsions of cod-liver oil combined with drugs, such as creosote, hæmoglobin, and glycerophosates; Zotal, a useful miscible disinfectant; Xeroform, an odourless substitute for iodoform; Unguentum Heyden, a colourless form of mercury for inunction; Omorol, a novel silver compound, and many other interesting exhibits. Cadbury and Fry both had their delicious chocolates and cocoas on view, and neither of these firms needs any recommendation except that of memory. Anæsthetics recall the name of Duncan, Flockhart and Co., but it may not be so generally known that they also supply preparations of all kinds of other drugs. Their Sapo Antisepticus Aethereal is an ethereal soap combined with 1-1000 iodide of mercury, and their Baumol soap forms a capital base for any medicament to be used in the toilette of the skin. Keen, Robinson and Co. had a new thing in Waverley Oats, and Robinson's Groats and Barley were there lest they should be overlooked after many years' service. The alkaloid products of the Abbot Alkaloidal Company showed what can be done by brains to make drugs portable, tasteless, and efficient; their granules and tablets being marvels of neatness. Novocain, a new substitute for cocaine, which can be sterilised by boiling and is of low toxicity, was shown by the Saccharin Corporation, Ltd.; and Angier's emulsion and throat tablets by the Angier Chemical Company. Messrs. E. Merck were introducing a large number of promising goods—drugs, serums, and various chemicals. Stypticin, a soluble hæmostatic and sedative for intra-uterine use, we had not met with before, and Bromipin, Iodipin and Dionine all invited experiment, so promising did they seem. Plasmon has now assumed many forms, and International Plasmon, Ltd., had much to show, especially a Plasmon luncheon-basket that looked very inviting. Messrs. Allen and Hanbury had a noble show of instruments of all sorts and descriptions. A peculiarly neat instrument, combining the purposes of a pair of scissors and a frænum refractor, should come into use for circumcisions, and self-retaining retractors for abdominal and other work were shown in great variety. Messrs. Ingram and Royle had a fine lot of mineral waters from nearly all the spas of Europe, and also a show of pastilles. Diuretin, Tannalbin, and Ichthalbin were amongst Messrs. Knoll and Co.'s fine products, and their dermatological preparations—Lenigallol, Iodoform Albuminate, Eugallol, and Anthrasol—are as elegant as they are ingenious. So, too, with Messrs. Newbery and Sons, who presented a number of the useful manufactures of Messrs. Warner and Co., all very interesting. Antiphlogistine was the sole exhibit of the Denver Chemical Company, and it is already too well known to need any particular description from us. We may, however, add as something new concerning it, that Emeritus Professor Piffard, of New York University, said at a recent meeting of the Dermatological Society that "he had obtained the most benefit in treating X-ray burns with Antiphlogistine." Castor oil in powder should be a blessing to medical men with young and refractory patients; it, and powdered cod-liver and other oils, presented by Mr. Rudolph Demuth, invited trial. Finally, there was Messrs. George Bach and Co.'s "G.B." Diabetes Whisky, which is one of the few prescriptions patients never object to. We could continue our description of the products exhibited, doing but little justice to each, we fear, for several columns more; but we have probably said enough to make medical men realise that it will be well worth their while to see next year's exhibition.

THE DUBLIN UNIVERSITY COMMISSION.

The appendix to the First Report of the Dublin University Commission (*a*) contains much more matter of interest than it is possible for us to deal with in the space at our disposal. The present volume consists entirely of statements and returns furnished to the Commissioners by various persons and bodies interested in education,—such as the Provost and Fellows of Trinity College, the Professors of Trinity

(*a*) "Royal Commission on Trinity College, Dublin, and the University of Dublin. Appendix to the First Report." Dublin. H. M. Stationery Office, 1906. Price 1s. 4d.

College, and Dublin University, the Synod of the Church of Ireland, the Bishops of the Roman Catholic Church in Ireland, and the General Assembly of the Presbyterian Church, and others.

It will be remembered that the terms of reference of the Commissioners are very wide, but their duties centre round the main questions:—(1) The possibility of the solution of what is known as the Irish University question on the basis of Trinity College or the University of Dublin. (2) The need for and nature of internal reform in Trinity College. As to the first question, it is obvious that if any settlement of the university question is to be arrived at, there should be some possibility of an agreement between Trinity College on the one hand and the heads of the Roman Catholic Church on the other. The views expressed in the Report make clear the improbability of any such agreement. On the one hand, there is practical unanimity among the Provost, Fellows, and Professors of the College against any scheme of planting side by side with Trinity College another college in the University. On the other, the Roman Catholic Bishops declare that "the Catholics of Ireland would be prepared to accept any of the following solutions:—(1) A university for Catholics; (2) a new college in the University of Dublin; (3) a new college in the Royal University; but that on no account would they accept any scheme of mixed education in Trinity College, Dublin. As the latter is the solution approved of by the staff of Trinity College, the hopelessness of the situation is obvious. If the Commission can find a way through the impasse, they will well have earned the gratitude of the country.

As regards the second point, it is probable the Commission will find their task easier. Every one is agreed that the present Fellowship system—election for life on the results of a competitive examination held in a few subjects—is bad, and out of date. Most of the suggestions put forward are on the lines of granting a certain number of fellowships for research work, and of appointing a number of readers for short periods.

The present system of government of the Colleges by the Provost and seven Senior Fellows—comes in for very general condemnation. It is suggested that the place of the present Board should be taken by an elective body, on which should be represented not only the Fellows, but also the Professors, and the general body of graduates.

The professors of the medical school make strong pleas on behalf of further provision for research by young graduates. This problem is more difficult in Dublin than elsewhere, since nearly all the Dublin graduates are poor men who cannot engage in research work unless not only the actual expenditure is met, but a means of livelihood provided for them during the time they are occupied in the work.

The returns of income and expenditure—hitherto kept secret with the greatest care—will attract attention. The total income during last year was £70,932 6s., the expenditure £69,355 14s. 4d. The salaries of the Provost and Fellows accounted for £21,000, and the expenses of the medical school for £5,764, the divinity school £3,072, the law school £712, and the engineering school £1,394.

REVIEWS OF BOOKS.

BROADBENT ON HEART DISEASE. (a)

SIR WILLIAM BROADBENT has entrusted the preparation of this fourth edition of his well-known work to his son, Dr. John Broadbent, who has revised and re-written several chapters. Sir William Broadbent has, however, re-read the complete work in its passage through the press, adding his valuable matured experience to the chapters on angina pectoris, and on functional diseases of the heart, which in the past have caused the work to be referred to as the most reliable text-book on the subject of which it treats. This revised edition may be taken as presenting a clear statement of the subject in brief, simple language, without either "padding" or the recitation of superfluous cases (which makes the reading of many present-day books a wearisome and unprofitable labour), and as a trustworthy, valuable, and suggestive guide, founded on long experience, accurate observation, and a thorough knowledge of the literature of the subject.

We would like to have had a still more generous treatment of the subjects dealt with in Chapters XXVI. and XXVII.—viz., Functional Affections (so-called) and Disorders of Rhythm of the heart, for it is here that practitioners would eagerly look for enlightenment from a long and large experience such as the author's. What a chapter, for instance, might be written on cardiac pain!

On page 14 will be found this statement: "The systolic murmur heard at the apex always signifies more or less regurgitation through the mitral orifice." That the author intended to qualify this more than he has done is evident from the following (page 15): "A pulmonic or aortic systolic murmur may be conducted to the apex, but it will be of diminished intensity and will not, as a rule, be conducted towards the axilla." We heartily recommend this work to all practitioners who wish a thoroughly trustworthy, readable, and scholarly monograph on cardiac disease.

(a) "Heart Disease and Aneurysm of the Aorta." By Sir William Broadbent, Bart., K.C.V.O., M.D.Lond., F.R.S., D.Sc., LL.D.Edin., F.R.C.P., Physician in Ordinary to H.M. the King, and to H.R.H. the Prince of Wales. Consulting Physician to St. Mary's Hospital and to the London Fever Hospital, etc., etc.; and John F. H. Broadbent, M.A., M.D.Oxon., F.R.C.P., Physician to Out-Patients, St. Mary's Hospital. Assistant Physician to the London Fever Hospital. Fourth Edition. Pp. 479, with 39 illustrations. London: Bailliere, Tindall, and Cox. Price 12s. 6d. net.

"THE EDINBURGH MEDICAL JOURNAL." (a)

THIS half-yearly volume contains no less than forty-four original communications, many of which are of considerable interest. Some of them have already been noticed in our weekly "Summary," and, in consequence, it is unnecessary to make mention of them here. Perhaps the most striking paper of the entire number is the abstract by Ford Robertson of his Morison Lectures on the Pathology of General Paralysis of the Insane. In it he gives a short account of his investigations into the matter, and states his grounds for believing that the cause of the disease is a diptheroid organism. Another interesting paper is that by Dr. Franze on "Estimation of the Functional Power of the Heart by the Aid of Ortho-Diagraphy." Dr. Franze has lately contributed papers on the same subject to other journals, and may be regarded as the pioneer of the method in this country. In his article he lays stress on the importance of an estimate of the actual size of the heart by means of X-rays, and points out that, as ordinarily examined, the cardiac shadow is necessarily much larger than the size of the organ itself. He then describes and figures Moritz's orthodiagraph, an instrument which has been devised to overcome this difficulty, and points out that by its aid definite information concerning the size of the individual cardiac chambers can be obtained. Dr. Llewelyn Jones contributes an important clinical paper on Spondylitis Deformans, and sums up the features of the syndrome as follows:—(1) Greater or less immobility of the entire spine or part of it, without marked pain on pressure or concussion; (2) Backward bowing of spine, especially of chest region, causing the head to be thrown forward and the chin depressed; (3) Weakening and possible atrophy of muscles of rump, neck, and extremities; (4) Various irritative phenomena, as paræsthesia, pain in neck and back muscles, etc. This paper is well worthy of careful study, and throws light on a condition which is, as a rule, very inadequately discussed in standard works. Space forbids us to more than mention Moynihan's paper on Courvoisier's law and Fowler's on Osteogenesis Imperfecta. We recommend the volume to all those who do not take the journal monthly.

ANATOMY. (a)

Considering the large size of this text-book, and the number of other excellent works of the same nature it has to compete with, it is undoubtedly a matter of congratulation for the editor and his collaborators, that a second edition should be called for within four years of the first. The general appearance and style of the volume remain unchanged, but considerable alterations in detail have been introduced, and many illustrations have been added, so that on the whole the edition compares most favourably with the preceding one. In the section on Osteology the outline markings of muscular attachments on the bones have been left out in the illustrations. This is probably partly due to the fact that many of those figured in the first edition were incorrect, and from that point of view the change is a welcome one, but we regard it as a mistake not to have substituted more reliable drawings, instead of omitting the outlines altogether. We are told, indeed, in the preface that some special work has been done in the mapping out of muscular areas, but the illustrations given are included in the section on Myology. Considering that many students make a practice of "learning their bones" from a systematic text-book, and of learning the muscles either from observation in the dissecting-room, or from a smaller work on regional anatomy, we look upon this arrangement as a mistake, although, indeed, the wood-cuts of the bones have gained considerably in appearance thereby. The radiographs of the foetal hands and feet which have been introduced to illustrate the description of the ossification of those parts, are an interesting addition, and it seems almost a pity not to have made more extensive use of this means of illustration. Before leaving the section on Osteology we would like to call attention to the figure of the temporal bone on page 116. The perspective in it appears to us to be faulty, and it at any rate falls far short in artistic merit of the other figures of the same bone. The section on Arthrology has been greatly improved by the use of colour in the engravings, and is now quite up to the standard of the rest of the work. In figure 234 on page 299 the popliteus muscle is not shown quite correctly, but otherwise we have no fault to find, while we may add that the figures illustrating the ankle joint, and the tarsal and metatarsal ligaments are in every way most admirable. We wonder if the author has ever seen anything quite so perfect in the course of actual dissection.

We have already adverted to the figures that have been introduced into the section on Myology to illustrate muscular attachments, and need not further refer to them. The use of colour for the muscles adds greatly to the figures in this section, and makes them much easier to understand.

There is but little change in the sections on the Nervous and Vascular systems. The description of the Central Nervous System from the editor's pen still continues to be the best of its kind in the English language. It is both clear and complete, and leaves little to be desired. Incidentally, we may remark that the use of colour would be of great assistance in showing up the relations of the peripheral nerves as shown in Dr. Paterson's section, and that the figure of the superior maxillary nerve on page 682 might have been made more elegant before including it in the present edition. The chapter on the Urogenital, or, as the editor now prefers to call it, the Urinogenital system, has been considerably improved by the addition of new illustrations, and by some new matter in the text. It still shows, however, a fault that was most noticeable in the first edition, and that is this repetition of figures. Throughout the whole book this repetition is indeed found—*e.g.*, figure 344 and figure 655 appear three times each throughout the volume, but in no section save the one now under comment does one meet with the same illustration repeated within a few pages of its previous appearance; in fact, within the compass of eighty pages we find at least eight individual figures repeated. The comment on this fact is obvious. We are glad to notice that some reference is made to the renal fascia, but are surprised to notice that the index does not contain any record of it. A little more detail is given concerning the prostatic capsule, but we think that the writer might have been a little more dogmatic in defining and applying terms; in fact, he might have given an anatomic and much-wanted lead instead of avoiding, as he does, the use of terms. A disposition to "hedge" is shown elsewhere, for the writer has apparently not made up his mind definitely as to the position of Bartholin's glands. He figures these indeed superficial to the triangular ligament, but does not state definitely in the text that that is their position, although he must surely be aware that it is a disputed point. But little change has been made in the article on the ductless glands, except for a little more extensive information on the Parathyroids, and on the Carotid and Coccygeal glands. A curious slip has crept into the description of figure 877 on page 1,221. It is apparently intended to show the relations of the coccygeal body to the middle sacral artery, but instead of the word coccygeal the word carotid has been used altogether eight times. Some other slips and misprints might be referred to, but they are mostly unimportant. We were interested to notice in this section two references to the Chromaffin system of the body. They show that the editor not only believes in being up to date, but also in keeping well abreast of recent research in the record of facts to be brought before students. The article on applied anatomy has been amplified, and has had one very important illustration added to it, namely, a drawing of a dissection of the spleen from the side. This is a most beautiful picture, and of high teaching value. We wonder that the editor considers it necessary or advisable to retain this brief chapter on such an extensive subject as Surgical Anatomy when there are now so many excellent monographs on the subject. Looked at as a stimulant to further reading, however, it perhaps justifies its retention.

(a) "Text-Book of Anatomy." Edited by D. J. Cunningham, F.R.S., Professor of Anatomy, University of Edinburgh. Second and thoroughly revised edition. Edinburgh and London: Young, J. Pentland. 1906.

ABDOMINAL OPERATIONS. (a)

This book on Abdominal Surgery includes only those operations which are common to both sexes. No gynæcological operations are described, and operations on the kidney or bladder, and operations for hernia are not included. The book consists of five sections, the first containing short chapters on Bacteriology, Preparation and After-treatment, the Treatment of Peritonitis, etc., the other sections containing descriptions of operations on the Stomach, Intestines, Liver, Pancreas, and Spleen. Throughout the book, while all the recognised operative methods are well described, there is a definite sense of individuality which is unusual in books on operative surgery. In many instances, not only is the operation described, but a clear account is given of the indications for the operation and a table of the immediate results and subsequent history is given. In the treatment of gastric hæmorrhage, Mr. Moynihan lays down as the safest course, the securing of the bleeding point followed by a gastro-enterostomy, but it is evident from the cases quoted that Mr. Moynihan is satisfied that the performance of gastro-enterostomy alone is effectual in checking the hæmorrhage. The description of posterior gastro-enterostomy is admirably clear, and the eight points to be observed sum up the operation well. It might have been better perhaps if the illustrations (pp. 147 *et. seq.*) had been arranged horizontally instead of vertically; as it is, such an expression as "the left end of the incision" (p. 150) is meaningless. It is interesting to notice than Mr. Moynihan considers the operation of pyloroplasty an unsatisfactory one. In the description of operations for cancer of the stomach, a good account is given of the gastric lymphatics, and the suggestion that, in partial gastrectomics, all idea of end-

(a) "Abdominal Operations." By B. G. A. Moynihan, M.Sc., Lnd., F.R.C.S. Philadelphia: W. B. Saunders and Co. 1905. Pp. 670.

to-end anastomosis of stomach and duodenum should be given up, is of great value from the point of view of free removal. In the section on Intestinal operations, Mr. Moynihan takes a definite stand on the use of mechanical appliances for anastomosis; "the use of mechanical appliances is no longer necessary, these have played their part in the development of surgical work, and it is now time that their use should be abandoned." Mr. Moynihan advocates union by a double row of continuous sutures, and the details of this method are repeated on several occasions. In the chapter on Obstruction a great point is naturally made of the necessity for emptying the gut above the obstruction, and an ingenious method of draining through a tube upon which the intestine is drawn, is described. In a few words Mr. Moynihan emphasises a rule which is now well recognised, *vis.*, "there are few rules so binding upon the surgeon as that which prohibits the resection of growths and end-to-end anastomosis of the large intestine in cases of acute obstruction." In the section on Liver Surgery, the method of rotation of the liver, first described by Mayo Robson, is extensively employed. The immediate closure of the gall bladder after the removal of gall stones is "unequivocably condemned" but cholecystectomy is advocated in cases of hydrops or empyema of the gall bladder consequent on impaction of a stone in the cystic duct. In the operation of cholecystenterostomy Mr. Moynihan advocates a lateral anastomosis between the two limbs of the intestinal loop. On the question of infection of the gall bladder from the intestine after this procedure Mr. Moynihan is not positive. On p. 569 he says: "The intestinal contents are in this way short-circuited, and there is no risk of infection of the gall bladder from the intestine"; while on p. 611 he says: "the risk of this infection is lessened considerably, but is not abolished." The section of the Surgery of the Pancreas and Spleen is an admirable summary of the most modern work in this region. The book, as a whole, is a very valuable contribution to Abdominal Surgical literature, and though of a formidable size, is, by reason of its clear style, easy reading, while the wealth of admirable illustrations makes it easy to follow the steps of the operations.

CLINICAL BACTERIOLOGY. (*a*)

ALTHOUGH under an extended title, this constitutes the second edition of Dr. Emery's excellent "Handbook of Bacteriological Diagnosis for Practitioners." Manifestly it has served its purpose as a simple, practical guide to practitioners lacking in pathological technique, and yet conscientiously desirous of availing themselves of the most reliable aids to clinical precision, and in this new and amplified form will be found ample information to place the busy doctor abreast with the fast-moving times. The hæmatological portion is almost entirely new. It is on much the same lines as the purely bacteriological section. Conditions requiring examination are explained, methods detailed, deductions indicated, and cautions given. Dr. Emery wisely points out that "the results of a blood examination are similar to those of other physical examinations; they are easy to obtain, but often very difficult to interpret."

The work is admirable in that it gives complete and thoroughly practical information. It is just what the work-wearied general practitioner requires to help him in the duties and difficulties of his profession. Every page bears evidence of very thorough revision, and there is a conspicuous up-to-dateness everywhere manifest. There is a very lucid description of the circulation of the opsonic power of the blood, full particulars regarding lumbar puncture, and a description of the best means of demonstrating Schaudimi's spirochæte of syphilis. The section on Cyto-Diagnosis, although short, is explicit, and well presents our reliable knowledge regarding this necessarily limited means of investigation. The illustrations throughout are most helpful. The work has been well planned, faithfully executed, and will be widely appreciated.

(*a*) "Clinical Bacteriology and Hæmatology for Practitioners." By W. D'Este Emery, M.D., B.Sc.Lond., Clinical Pathologist to King's College Hospital, and Pathologist to the Children's Hospital, Paddington Green. Pp. 240, with 10 plates and 47 figures. London: H. K. Lewis. 1906.

LITERARY NOTES.

THE "TIMES," THE PUBLISHERS, AND THE BOOKSELLERS.

A GREAT commotion has manifested itself in the book trade between the Publishers' Association and the proprietors of the *Times* newspaper, and a crisis has now arisen in which neither side is prepared to give way. In its ultimate issue the medical profession is only indirectly interested, as the question of medical books has not arisen. Their price of publication has always been and must necessarily be high when compared with fiction, on account of the costly nature of production and the limited field of readers. The fight relates primarily to novels and historical literature, in which the author, publisher, bookseller, and the public generally are greatly interested.

LAST year the *Times* started a book club, having for its objects the securing of additional subscribers and advertisements for this newspaper. That the *Times* was sadly in want of fresh advertisers is shown by the fact that in its columns will now be found a host of quack advertisements that, prior to the American control, were excluded and condemned by its editors. By the tempting offer of a book club, from which the public were promised the supply of any number of books immediately on publication, and the subsequent sale to them of such books at a price far below that possible by the bookseller, the *Times* netted a considerable number of new subscribers.

"So far so good" as between the newspaper and its readers; but the bookseller has something to say. He tells the publisher that the *Times* has ruined his business, and that he cannot now sell books, as his former customers can get them at half their nominal value, and that if the system continues their shops must be closed, as their occupation has gone. The publisher is thus faced with the startling problem that the thousands of allied tradesmen in all parts of the kingdom to whom he has looked for the disposal of his wares, will be no longer available, and that a gigantic monopoly will result in disaster all round.

EACH side in the contest protests that the fight is in the public interest, which is, of course, nonsense, and the crux resolves itself into one of endurance—a strike, in fact, the end of which it is impossible to forecast. For ourselves we can only express regret that the *Times* has stooped to the arena from its once deservedly lofty position as "the leading newspaper of the world." In that capacity it surely had ample scope, while in the mundane condition of "income" public opinion voted it prodigious. Such being admitted, we submit that it was scarcely worth competing as a second-hand bookseller to ruin the thousands of that ilk.

AT a meeting of the master, wardens, and court of assistants of the Society of Apothecaries of London held at their hall on Tuesday, the honorary freedom of the society was conferred upon Alderman and Sheriff Crosby, who is a licentiate of the society. The master, Mr. E. Parker Young, and wardens subsequently entertained at dinner Dr. Crosby, the members of the court of examiners, the deans and wardens of the Metropolitan schools of medicine, and a large number of the livery of the society.

MR. HENRY S. WELLCOME, who established the Wellcome Research Laboratories at the Gordon Memorial College, Khartum, three years ago, has sent a donation of fifty guineas towards the endowment fund of the London School of Tropical Medicine.

Medical News in Brief.

Royal College of Surgeons of England.

At a quarterly meeting of the Council held on Thursday last, Mr. Henry Morris, President, in the chair, the annual report of the Council to be presented at the meeting of Fellows and Members of the College on November 15th was approved and adopted. The report contains a record of the work of the College in its various departments during the past collegiate year. Besides dealing with the reports of several committees, it contains articles dealing with the length of the medical curriculum, the position of the college as a qualifying body, a proposal to institute a diploma in tropical medicine, and the working of the Midwives Act (1902). During the year with which the report deals, the following diplomas have been issued: Membership, 423; Fellowship, 42; Licence in Dental Surgery, 87; and the Diploma in Public Health, 33. The re-decoration of the museum, begun in 1903, has been completed at a cost to the College of over £1,000. The presentations to the museum have been well kept up, and the donations to the library include many interesting pamphlets and volumes of MS. writings. During the past year the number of readers in the library has been 11,267. The deaths of 20 Fellows and 264 Members of the College have been reported.

The two following members of the College, having passed the required examinations and conformed to the bye-laws, were admitted Fellows of the College: David Kirkpatrick Coutts, M.B.Lond., St. Thomas's Hospital; and Robert Rutson James, L.R.C.P.Lond., St. George's Hospital. Diplomas of Membership were granted to: George Ford, Toronto University and University College Hospital; and Wolbert Ernest McClellan, Toronto University and London Hospital. Diplomas in Dental Surgery were issued to the following candidates: Reginald Hudson Astbury, Birmingham University; William Alfred Helyar, Guy's Hospital; Ernest Gibbon, Durham University; Percy Vivian Giles Pedrick, Guy's Hospital; and Charles Cook Pooley, Middlesex and Royal Dental Hospitals.

An honorarium of £100 was presented to Mr. William Pearson, the prosector in the museum, "in recognition of his valuable work, and of his having completed fifty years in the service of the College."

It was decided to publish a revised edition of Part I. (Man) of the Osteological Catalogue. The loan of museum specimens to the Army Medical Department for examination purposes was renewed for another year. Mr. Godfrey Alan Walker, until lately a student at Epsom College, and now at the London Hospital, was nominated by the Council as the fourteenth Jenks Scholar.

The Royal College of Surgeons in Ireland and the University of Aberdeen Celebrations.

The following is the text of an address presented by Mr. Henry R. Swanzy, President of the Royal College of Surgeons in Ireland, in the name of the College, on the occasion of the recent quater-centenary celebrations of the University of Aberdeen

PRÆCLARÆ UNIVERSITATI ABERDONENSI REGIUM COLLEGIUM CHIRURGORUM APUD HIBERNOS, S.P.D.

Vehementer vobis, viri illustres, gratulamur quod quattuor sæculis prospere decursis quintum iam auspiciis faustissimis incohatis.

Universitas Aberdonensis cum primum orta est anno post Christum natum MCCCCXCV in ipsis incunabulis Facultatem Medicinæ longe in his finibus antiquissimam instituit cuius rei gratia sit conditori vestro sagacissimo Guilelmo Elphinstone.

Unde est orsa in eo perstitit atque nunc perseverat. Per annos iam quadringentos hæc regna, imperium Britannicum, cuncti denique homines Universitat vestræ Scientiam Disciplinamque Medicam auctas fotas ornatas gratis animis assignarunt et assignant.

Anatomiam Activam, quæ dicitur—studium arti quam præcipue nos colimus coniunctissimum—usque ab anno MDCXXXII. auccessu optimo exercuistis.

Iuvat referre nomina Professorum et Alumnorum Aberdonensium qui in summam claritudinem rei Medicæ et peritia et exercitatione pervenerunt. Ne taceamus Andræum Moir, Guilelmum Pirie, Matthæum Duncan, Andræum Clarke, quattor denique Gregorios qui de Schola Medica intra muros Academicos condenda tam bene meriti sunt. Plures immo plurimos alios viros insignes memorare liberet, sed finibis certis continemur ultra quos veremur ne iam iam egressi simus.

Restat ut Universitati Aberdonensi totis animis de hac tam felici occasione etiam atque etiam gratulemur et vota dignissima nuncupemus pro perpetua eius incolumitate fausto que novi sæculi initio.

Nomina Subnotabamus,
Henricus R. Swanzy, Præses.
Johannes Lentaigne, Præsidis Vicarius.
Carolus Cameron, Secretarius.

Id. Sext. MCMVI.

North-East London Clinical Society.

The annual dinner of this society was held on Thursday, October 11th, 1906, at the Abercorn Rooms, the President, Dr. A. E. Giles, occupying the chair. After the loyal toasts had been honoured the health of the society was proposed by Sir Halliday Croom, who had delivered the opening address before the members on the same afternoon. The President, in replying, sketched the origin and progress of the society, which, although comparatively young, had yet made its influence felt over a very wide area, and boasted of a considerable membership. Dr. Herbert Powell proposed the toast of the Tottenham Hospital, which was so intimately connected with the life and work of the society, to which Mr. C. Churchill, Vice-Chairman of the hospital, suitably replied. Among the numerous visitors present, including ladies, were Sir William Broadbent, Mr. James Cantlie, Dr. Percy Kidd, Mr. Langton, and the Rev. F. B. Johnston, vicar of Waltham Abbey. An efficient and varied musical programme was provided,

Suggested Outside Hospital Service.

Mr. Wellington held an inquiry at Westminster last week concerning the death of Harold Aitchison, 27, of Walthamstow, a draughtsman, engaged in Victoria Street.

It was stated that the deceased man, who was sitting before his drawing-board, suddenly fell back. Witness caught him in his arms, and sent for medical aid. It was twenty-five minutes, however, before a doctor could be found, Twice witness sent round to Westminster Hospital, but they would not send a doctor or an ambulance. Mr. Aitchison expired in witness's arms.

Dr. Trevor gave evidence that death was due to heart trouble, and the jury returned a verdict accordingly.

Another representative of the firm said he offered to take Mr. Aitchison across to the hospital if only the hospital would lend an ambulance, but this request was refused.

The Coroner: The hospitals are always ready to receive patients, but they cannot supply doctors to the public.

The Foreman: I should have thought that in an emergency case like this a doctor might have been sent.

Dr. Trevor, who is on the staff of St. George's Hospital, remarked that doctors were not sent out by that institution.

The assistant secretary of the Westminster Hospital has since stated that it was a rule of the hospital that their medical staff should not be called to treat cases outside except in cases of dire emergency. On the question of not lending the ambulance the hospital possessed no litter suitable for the purpose.

Quackery in Germany.

In his recently published work on quackery and the means of its prevention, Dr. Henry Graack estimates the number of quack doctors practising in the German Empire at 10,000, without reckoning the vast number of quack dentists. The number of qualified doctors practising in Germany is 31,000.

The New Wing to the Acland Home, Oxford.

A new wing, containing operating and sterilising rooms and open-air balconies, recently added to the Acland Home at Oxford, was opened on Saturday last by Dr. Osler, the Regius Professor of Medicine, who read a congratulatory letter from the Queen. Professor Osler pointed out that a home of this description, erected in memory of Mrs. Acland and Sir Henry Acland, was particularly useful for acute surgical cases and enteric fever. Undoubtedly nervous diseases were increasing, and as a rule they were better treated away from home. There were, moreover, some 3,000 undergraduates at Oxford, and it was right there should be an institution where they could be cared for when ill. A University sanatorium was not necessary, because the home supplied its place, and many of the undergraduates, when need arose, received the benefit of the home.

The Vivisection Commission.

At a meeting of the committee of the British Union for the Abolition of Vivisection the following resolution was unanimously passed and directed to be forwarded to the Home Secretary: "This Committee places upon record its deep regret that no accredited medical representative of the Anti-Vivisection cause has been accorded a seat upon the Royal Commission appointed to inquire into the working of the Cruelty to Animals Act, 1876. This regret is accentuated by reason of the fact that of the medical commissioners who have been appointed, one has been a licensed vivisector continuously since the year 1887, two others have taken out licences to vivisect at various times, and a fourth has expressed himself approvingly of the practices. The Committee are of opinion that in view of the preponderating number of commissioners presumably favourable to the practice who have been already appointed there should be added at least one medical representative chosen from among the anti-vivisectionists in order to ensure confidence among the many thousands of his Majesty's subjects interested in this matter that there will be a full elucidation of facts from the evidence of witnesses on both sides."

Society for Relief of Widows and Orphans of Medical Men.

A quarterly Court of the above Society was held on Wednesday last, Dr. Blandford, president, in the chair; fourteen directors were present. Proposals for membership were read from two medical men, and they were duly elected. Since the last Court, two widows, annuitants of the Charity, had died, one had become ineligible, owing to an increase of income. Of the two who had died, one had received in grants £621 and the other £500, their husbands having paid in subscriptions £52 10s. and £15 15s. respectively. The one who was no longer eligible had received £900, her husband having paid a composition fee of £21, for life membership, at the time of his election. It was proposed to distribute the sum of £556 among the annuitants of this Charity as a Christmas present, each widow to receive £10, each orphan £3, and those on the Copeland Fund £5 each. Six letters asking for relief had been received during the last quarter, but this had to be refused owing to the applicants being ineligible under the by-laws of the Society, relief being only granted to widows of deceased members and to orphans below the age of 16. Any registered medical practitioner, resident within a radius of 20 miles from Charing Cross, is eligible for membership. Further particulars may be obtained from the Secretary, 11, Chandos Street, Cavendish Square, London.

Inquest on an Irish Surgeon.

It was stated at an Holborn inquest on the 12th inst. on Daniel Power, F.R.C.S., 48, Medical Officer of Kildare Infirmary, Kildare, Ireland, who died suddenly in lodgings at Gower Street, W., on Wednesday, that he had visited Harrogate. Soon after returning to London he died.

Dr. Ross, of Harley Street, who made a *post mortem* examination on the body, said the deceased's heart was the largest he had ever seen. It was 130 per cent. too heavy, and weighed 11lb. 2 ozs. The Harrogate waters had the effect of upsetting the stomach, and, added the doctor, practically killed the deceased. Death was due to heart disease. The jury returned a verdict in accordance with the medical evidence.

Bequests to Charities.

The death was announced on the 13th inst. of Mrs. Lewis Hill (widow of Mr. Sam Lewis, the well-known moneylender, who afterwards married Capt. Hill, at Grosvenor Square, London, after a long illness.

Mr. Sam Lewis, when he died, left a fortune amounting to between £3,000,000 and £4,000,000.

Much of this vast sum now goes to charities. His widow received £1,000,000 and a life interest in the remainder of the fortune, but the husband left directions as to the charities which were to benefit at her death.

The will set out the following sums for charities at the death of Mrs. Lewis:—

£400,000 for dwellings for the poor.

£250,000 to the King Edward Hospital Fund.

£100,000 to the Jewish Board of Guardians for relief of the poor and establishing a convalescent home or hospital on the sea coast.

£20,000 to the London Hospital for founding and endowing the Ada Lewis ward.

£15,000 for Maidenhead and Cookham charities.

£15,000 (interest on) for Jewish poor in Dublin.

£10,000 for Ada Lewis wing of Maidenhead Hospital.

£5,000 to Ada Lewis ward of Evelina Hospital for sick children.

£5,000 to Paddington Green Children's Hospital.

£20,000 to the Sisters of Nazareth, Hammersmith.

£10,000 each to Guy's, Charing Cross, St. George's, St. Bartholomew's, St. Thomas's, Consumption and Diseases of Chest, Brighton, Metropolitan, and University College Hospitals.

£5,000 each to the Jewish Soup Kitchen and the Royal London Ophthalmic Hospitals, etc., etc.

One million pounds is thus to be expended by the trustees of the estate.

Half of the remainder of two-thirds of the great fortune is to go to King Edward's Hospital Fund, which has already received £250,000, and the other half to the trustees, who have received £400,000, for establishing dwellings for the poor.

The executors and trustees are Mr. E. H. Davies, Mr. A. Jacobs and Mr. A. E. Sydney.

X-Rays and Ringworm.

The Metropolitan Asylums Board, at their meeting last week considered a proposal to reduce the nursing staff at the Downs School for the treatment of ringworm cases, in consequence of the greater rapidity in the cure effected by the introduction of the X-ray treatment. There will be a saving of £204 in salaries, and £28 per annum in each case for lodgings.

Death under an Anæsthetic.

An inquest was held recently on a man named Parker, whose death occurred at the Bristol Royal Infirmary whilst under an anæsthetic. Dr. Williams stated that deceased visited the institution in order to undergo an operation for fistula. He was given an anæsthetic, but expired before the operation commenced, death being due to heart failure. A verdict in accordance with the medical evidence was given.

PASS LIST.

University of Glasgow.

THE following candidates have passed the second professional examination for the degrees of M.B. and Ch.B. in the subjects indicated (A., Anatomy; P. Physiology; M., Materia Medica and Therapeutics):—

John Andrew Aitken (P.), David Anderson (M.), Donald Arbuckle (P.), Thomas Archibald (M.), William Hunter Stirling Armstrong (M.), James Currie Auchencloss (P., M.), Alexander Ballantyne, M.A. (P.), William Barr (A.), Charles Bennett (A., P., M.), John Blakely (M.), John Lindsay Boyd (M.), Charles Brash (P.), William Barrie Brownlie (M.), David Young Buchanan (A., P., M.), Hector Mackay Calder (M.), John Cameron (M.), Matthew Ignatius Thornton Cassidy (M.), Donald James Clark (A., M.), James Cook (Coalburn) (A., P.), James Cook (Partick) (M.), Walter Dawson (A., M.), Thomas Loudon Fleming (M.), Thomas Scott Forrest (A.), William Leonard Forsyth (M.), John Fotheringham, B.Sc. (M.), William Ernest Gemmell (P.), Alexander Thomas Arthur Gourlay (A., M.), Thomas Edmondstone Gray (A., P., M.), Josiah Stranaghan Harbinson (M.), Michael Harkin (A., P.), Stephen John Henry (A., P., M.), James Hall Hislop (A., P., M.), William Alexander Hislop (A., P., M.), Benjamin Hutchison (M.), Walter Hermann Kiep (M.), Thomas Joseph Kirk (P.), John Lang (M.), Daniel Conway M'Ardle (A.), Angus Macaulay (P., M.), Alexander Macphail Macdonald (A., P.), William M'Kendrick (A.), Francis William Mackichan (P., M.), William Campbell Mackie (A.), Alexander M'Kinnon (P.), John James Mackintosh (A., P., M.), James Walter M'Leod (M.), John MacMillan (M.), Allan M'Pherson (P., M.), Murdo M'Kenzie M'Rae (P., M.), Andrew Maguire A., P.), William Aubrey Layard Marriott (P.), Frank Needham Marsh (A., P., M.), Kenneth Chisholm Middlemiss (M.), Robert Wright Mitchell (A., M.), John Mowat (P.), James Muir (A.), William Aikman Muir (M.), Charles Sutherland M'Kay Murison (M.), Archibald Naismith (M.), Watson Noble (P., M.), David Purdie (A.), Edward Quigley (A., P., M.), Richard Rae (M.), Henry Nimmo Rankin (P., M.), Nicol M'Nicoll Rankin (M.), Hugo Given Robertson (A., M.), Allan Semple (P., M.), James Brown Sim (M.), Alexander Hunter Sinclair (M.), James John Sinclair (P.), Donald Stewart (A.), Edward Ernest Stewart (P.), David Taylor (M.), Walter Telfer (P.), John Shedden Thomson (A., M.), Arthur Turnbull, M.A., (A., P.), Robert Macnair Walker (M.), David M'Gruther Wilson (A.), John Alexander Wilson (A.), William Mitchell Turner Wilson (A., P., M.), John Youngson Wood (P., M.), Hugh Young (A., M.), John Young (A., P.). Women—Margaret Baird Sproul Darroch (M.), Euphemia Adamson Hay (P.), Jessie Deans Rankin (A.), Olive Robertson (A., P.), Jessie Capie Russell (M.), Jeanie Hinshaw Stewart (P.).

The following have passed the third professional examination for the degrees of M.B. and Ch.B. in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

Murdo Buchanan (P., M.), James Cairncross (P.), John Craig Crawford (P.), Neilson Davie (M.), James Cowie Dick (P.), James Dunbar (P.), William Hunter Duncan (P., M.), Allan Dunsmuir (P.), Alexander Wylie Eadie (M.), William Marley Elliott (M.), John Ferguson (M.), Thomas Forsyth (P.), George Muir Fraser, M.A. (P., M.), Samuel Nicol Galbraith (M.), David Gibson (P., M.), John Vincent Grant (P., M.), James Dow Gray (P., M.), David Hamilton (P., M.), Alexander Mills Kennedy (P., M.), Charles Lawson Kerr (P., M.), James Towers Kirkland (M.), George Ligertwood (M.), Alexander Tulloh Inglis Macdonald (M.), James M'Donald (P., M.), Neil MacInnes, M.A. (P., M.), Robert M'Inroy (M.), Joseph Bogue Mackay (P., M.), Thomas Cooper Mackenzie (P.), James Hogg Martin (M.), William Spence Melville (M.), John Clark Middleton, M.A., B.Sc., P., M.), Allan Frederick Miller M.), John Wilson Miller (M.), Thomas Miller (M.), John Oswald (P., M.), Daniel M'Kinley Reid (P., M.), Thomas David Coulthard Ross (P., M.), James Alexander Stenhouse (M.), John Stewart, M.A., B.Sc., (P., M.), John Martin Taylor (M.), David Alexander Thomson, M.A. (P., M.), Hugh Johnstone Thomson (M.), John Archibald Thomson (P., M.), Thomas Macknight Watt (P.), John Weir (P., M.), David John Williams (M.), Garabed Yeghia Yardumian (P.), Matthew Young (P., M.) *Women.*—Margaret Gardner Forrest (P., M.), Ella Smith Hill, M.A. (P., M.), Annie M'Corrie (M.), Janet Annie Macvea (P., M.), Jane Isabel Robertson, M.A. (M.).

The following passed with distinction in the subjects indicated:—

First Examination.—In Botany and Physics.—James Hendry, M.A.; Thomas Jones Mackie, Andrew Bruce MacLean. *In Zoology and Chemistry.*—David Thomas Crichton Frew. *In Physics and Chemistry.*—James Jack. *In Botany.*—James Turner Brown. *In Zoology.*—Samuel Bryson, Jeanie Douglas M'Whirter, Barbara Grace Rutherfurd, Florence Elizabeth Sexton. *In Physics.*—David Rutherford Adams, Hugh Forrest, Andrew Garvie, Nicholas Gebbie, John Gray, Andrew Ross Muir, Daniel Wright Ritchie, Gilbert Innes Strachan, James Douglas Walker, Alexander Stewart Wilson, Henry Yellowlees. *In Chemistry.*—Peter Drummond, William Howat, M.A.; Harold Edward Whittingham.

Second Examination.—In Physiology.—Arthur Turnbull, M.A. *In Materia Medica and Therapeutics.*—John Fotheringham, B.Sc.; Walter Hermann Kiep, Robert Macnair Walker.

Third Examination.—In Pathology and in Medical Jurisprudence and Public Health.—John Clark Middleton, M.A., B.Sc. *In Pathology.*—Matthew Young. *In Medical Jurisprudence and Public Health.*—Alexander Wylie Eadie, Hugh Johnstone Thomson.

University of Durham.

At the Convocation holden on Saturday, September 29, 1906, the following degrees were conferred, viz.:—

Doctor in Medicine.—Lewis A. Clutterbuck, M.B., B.S., Durh.; Sophia B. Jackson, M.B., B.S., Durh.; Philip W. James, M.B., Durh.; Thomas C. Rutherfoord, M.B., B.S., Durh.; William Simpson, M.B., B.S., Durh.; John A. Swindale, M.B., B.S., Durh.

Doctor in Medicine for Practitioners of Fifteen Years' Standing.—Alfred J. G. Barker, M.R.C.S.; Frederick J. Brown, M.R.C.S., L.S.A.; James D. Cree, M.R.C.S., L.R.C.P.; Thomas L. Crooke, L.R.C.P. and S., E.; Edward J. Cross, M.R.C.S., L.R.C.P., D.P.H.; Matthew Dobbs, M.R.C.S., L.R.C.P., L.S.A.; Henry J. Edwards, L.R.C.P. and S., D.P.H.; Edward Ellis, L.R.C.P. and S., E.; Joseph W. Gill, M.R.C.S., L.R.C.P., D.P.H.; Frederick M. Graham, F.R.C.S., L.R.C.P., L.F.P.S.G.; Charles R. M. Green, F.R.C.S., L.S.A., D.P.H.; Hubert Joslen, M.R.C.S., L.R.C.P.; Arthur B. Kingsford, M.R.C.S., L.R.C.P., D.P.H.; Robert E. Lauder, F.R.C.S., E., L.R.C.P., D.P.H.; James Menzies, L.R.C.P. and S., E., L.F.P.S.G.; Charles J. Sharp, M.R.C.S., L.R.C.P.; Arthur G. Southcombe, M.R.C.S., L.R.C.P., D.P.H.; George G. Stuart, L.R.C.P. and S., E., L.F.P.S.G.

Master in Surgery.—Thomas Y. Simpson, M.D., B.S., Durh., M.R.C.S.

Bachelor in Medicine (M.B.).—Vincent E. Badcock, George E. Denholm, Reginald I. Douglas, M.R.C.S., L.R.CP.; Neville A. Eddlestone, Florence B. Lambert, Arthur C. H. McCullagh, Ernest Martin, L.R.C.P. and S., E., L.F.P.S., G.; Bertha M. Mules, Jessie J. M. Morton, Sidney Nix, L.R.C.P. and S., E., L.F.P.S., G.; Frederick C. Pybus, George R. Philipson, Donald M. Ross, Thomas L. Wormald.

Bachelor in Surgery (B.S.).—Vincent E. Badcock, George Denholm, Reginald I. Douglas, M.R.C.S., L.R.C.P.; Neville A. Eddlestone, Florence B. Lambert, Arthur C. H. McCullagh, Ernest Martin, L.R.C.P. and S., E., L.F.P.S., G.; Bertha M. Mules, Jessie J. M. Morton, Sidney Nix, L.R.C.P. and S., E., L.F.P.S., G.; Frederick C. Pybus, George R. Philipson, Donald M. Ross, Thomas L. Wormald.

Bachelor in Hygiene (B.Hy.).—Isaac Thompson, M.B., Ch.B., New Zealand.

And the following received the *Diploma in Public Health.*—Isaac Thompson, M.B., Ch.B., New Zealand; John Henry Tripe, M.R.C.S., L.R.C.P.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Case of Anastomosis between the Femoral Veins.—McGregor (*Glasgow Medical Journal*) reports the following case:—W. S., æt. 26, suffered from enteric fever seven years ago, when his left leg became painful and swollen. Three years later he got a second attack of enteric fever, shortly after which he noticed swollen veins on his abdomen. These veins increased in size for some time, and then became stationary. The patient came for treatment, as he feared they might burst. Inspection of the abdomen revealed a plexus of veins occupying the lower segment of the abdominal wall. This was triangular in shape with the apex situated at the umbilicus. The main trunks of this plexus were the superficial epigastrics and superficial external pudics of both sides. They were much altered in shape, being distended and somewhat tortuous. At the left inferior angle of the triangle there was a bulbous swelling, apparently the extreme upper end of the internal saphenous vein. One branch from this was directed horizontally across the pubis, becoming directly continuous with a similar vein on the opposite side. Another branch extended upwards and inwards towards the umbilicus. There was a similar arrangement of veins on the right side. The left internal saphenous vein was not visible in the thigh. The left leg below the knee was somewhat cyanosed as compared with the right. Otherwise the veins of the leg appeared normal. The left calf measured 1¼ inches more than the right. On testing the flow of blood in the dilated abdominal veins, it was noticed that the left side the blood flows from the saphenous opening across the pubis to the right. The left superficial epigastric vein flowed upwards towards the umbilicus, where it anastomosed with its fellow on the right, in which the blood flowed normally—*i.e.*, downwards. When the patient lay supine this plexus of veins was empty; when turned on his right side they remained so; but if turned on his left side they gradually filled. In this case, therefore, the obstruction must have been below the level of the junction of the iliac veins, since the right took up the work of the left. The question arose as to whether these dilated veins might be safely ligatured, and the less exposed deeper branches of the iliac vein trusted to take up the circulation. To ascertain this fact an inguinal truss was employed in such a way that the anastomosing veins would be compressed, and the potency of the normal channels thus tested. Though the patient was allowed to walk about all day, there was practically no difference between the measurement of the affected calf in the morning and the evening. The superficial pudic veins were ligatured on the 30th January, 1905, and the two superficial epigastric veins and their intercommunicating branches six months later. The patient has been at work continuously since the second operation, and no superficial veins are now prominent or visible on the abdomen. S.

Some Surgical Cases.—Major Gabbett, I.M.S. (*Indian Medical Gazette*, September, 1906) reports the following cases:—*Case I.*: Recurrence of stone four years after suprapubic extraction.—A boy of seven was admitted with stone in the bladder. Four years previously a stone had been removed by suprapubic route. The same route for operation was adopted on this occasion, and the bladder found fixed to the abdominal wall by scar tissue. This condition added no serious difficulty in the second operation, which was entirely successful, an oval stone about one inch in its longest diameter being removed. *Case II.*: Intraperitoneal Rupture of the Bladder.—A young, healthy native woman was seen in the out-patients' department complaining of pain and swelling of the abdomen following a kick two days previously. Examination revealed the presence of free fluid in the peritoneal cavity. The symptoms of hæmorrhage or well-established peritonitis were absent. Since the receipt of the injury no urine had been passed. On catheterisation five pints of blood-stained urine were drawn off, evidently from the peritoneal cavity. The patient was immediately removed to the operation table, and an incision revealed a ragged vertical rupture on the posterior surface of the bladder, reaching almost from top to bottom. Considerable difficulty was found in passing Lambert's sutures, so as to close the lower angle of the wound. Only one layer of catgut sutures was used. The bladder was now proved water-tight, and an indiarubber tube was passed down behind the sutures. An attempt was made to keep a catheter in the bladder, but as it was constantly removed by the patient the attempt was given up. On the third day there was a suspicion of urine sucked up from the tube by a syringe, and on the fourth no doubt existed that leakage had occurred. On re-opening the abdomen the greater part of the line of sutures was found to have given way, probably from absorption or slipping of the catgut. The edges of the tear were ragged, swollen, and so friable that resuturing was out of the question. The coils of the gut in the pelvis were sticky with commencing formation of lymph, and slightly adherent to each other. As a last resource four silkworm gut sutures were passed through the whole thickness of the bladder at some distance from the edges of the rent, one on either side of the lower angle, and one on either side of the upper angle. They were then drawn up in a purse-string manner, and fastened to the abdominal wall. A rubber tube was passed through the mouth of the so-formed purse into the bladder. The pelvis was then mopped with dry sponges, and the abdominal wall sutured as after a suprapubic extraction of stone. The sinus was healed six weeks afterwards, and the patient discharged as cured. S.

The Results from the Bloodless Reduction of Congenital Hip Dislocation.—Stern (*Medical Record*, 15th September, 1906), reports the results he obtained in fifteen individual hips operated on by the bloodless method. There were twelve patients treated. Failure in reduction occurred in three old-standing and well-developed cases. All refused a second trial, or a trial of Schlesinger's method. There was one total failure due to poor judgment in operating upon an unsuitable case. Six anatomical cures resulted, one ideal functional result, three transpositions with good function. One patient is still under treatment. By anatomical restitution is meant cases where the limbs are of equal length, the lordosis and waddling gait gone, the joint freely movable, the head of the femur entirely within the acetabulum, both to palpation and to X-rays, and where clinically such a hip does not differ at all from a normal joint. A perfect functional result means practically the same thing, only that clinical examination or X-rays reveal some gross anatomical abnormality. Posterior redislocation and relapses cannot be avoided. Many may be due to faulty technique, but most are due to some natural anatomical obstruction, shallow acetabulum, large head, excessive ligamentum teres, etc. These cases should be repeatedly subject to bloodless reduction, and where this finally fails the bloody operation should be done. Unsuccessful operations are due to two causes, the most important thing being the advanced age or excessive muscular development of the patient. Four to six years in bilateral cases and seven to ten in unilateral cases should be the upper age limits. Where the malformation of the parts is the chief obstruction to successful reduction, as, for instance, an hour-glass constriction of the capsule, arthrotomy as advocated by Bradford allows of perfect

exploration and removal of obstruction. The constant tendency for a reduced joint to redislocate may be overcome by the use of Werndorff's axillary abduction for a number of weeks, followed by ordinary primary position. Untoward results such as paralysis, fractures, gangrene, etc., cannot always be avoided, but are vastly less common than they were before the year 1900, when the use of traction instruments was entirely given up by the best operators. The author has compiled statistics of all hips which have been reported as successfully operated on during the last five years. Looking at the results from a functional standpoint alone, out of the total 2,593 cases, in 2,307, or 88.96 per cent., good functional joints have been obtained. S.

The Development of Lamellar Cataract.— H. B. Grimsdale (*The Ophthalmoscope*, August, 1905) has had the opportunity of watching the development of Lamellar Cataract in a boy aged 3, well-developed and healthy, with no signs of rickets. Beyond a "fit" at 12 months he had had none of the ordinary diseases of childhood. The child's sight had been noticed to be defective for some months, and was getting worse. Under atropine a "good reflex" was noted, but no details of the fundus could be made out. Although no separate opacities could be seen in the lens, Grimsdale had no doubt as to the cause of the bad vision, so he removed the lens by several needlings, after which he could see the fundus details. Before the boy left hospital the other lens showed definite opacities. After two years the boy returned, and then had a typical lamellar cataract in the eye which had not been treated. It would appear that the cataracts in this case were not congenital, as the parents were precise as to the onset of the bad vision. On account of the absence of nystagmus it was concluded that the sight must have been fairly good. M.

Myasthenia Gravis.—Taylor and Lawford (*Trans. Ophthal. Society*, Vol. XXIV.) record a case each. Taylor's case was that of a painter, æt. 46, who had suffered from colic and painter's gout. No history of paralysis. Ten years ago had ptosis, and during following six years had it intermittently. Nine years ago had diplopia, which became permanent for past four years. Weakness of lower limbs, arms, and hands. He could not read for long at a time. There was paralysis of ocular movements, pupils reacted to light, arm and leg movements easily exhausted, difficult mastication, but speech good. Myasthenic reaction in affected muscles. Reflexes and sphincters normal. Lawford's patient was a baker, æt. 51, and had good health up to 14 years ago, when he had influenza, after which lids commenced to droop, and got gradually worse. General weakness came on until Christmas, 1903, when he had to give up work. All the eye muscles were very weak, marked ptosis, pupils equal and active, media clear, normal fundi, visual acuity $^{6}/_{12}$. From the detailed history of the case, we gathered the following:—Temporal and masseter muscles weak, tongue protruded straight, but side motion is very weak; muscles supplied by seventh pair show loss of tone; is unable to whistle loudly, elevation of the soft palate is defective, fluids regurgitate through nose, and there is a nasal intonation; weak abduction of the vocal cords, walks slowly and is easily tired, flabbiness and weakness of muscles of arms, legs, abdomen, and back. Conjunctival reflex was dull. Palate and knee reflexes present; sphincters normal. The patient wore with comfort a pair of spectacles with wire lid-crutches fitted, which held up his lids and saved him having to throw back his head to see better, an action which he was unable to maintain for long. M.

Urinary Calculus and its Detection with the X-rays.—E. W. Shenton (*Lancet*, September 15), draws attention to the very general misconception with regard to the proper use of the X-rays in the detection of urinary calculus. It is now recognised that there are two methods in which the rays may be used—first, for screen examination, and secondly, for photographic effects; and beyond question the former is the more serviceable in diagnosing lithiasis. A difficulty frequently put in the way of the radiographer by the surgeon is the request for a skiogram of large dimensions, including both ribs, kidneys, and iliac crests. In a photograph so large as this, only the most opaque and obtrusive stones will show at all. The author then describes in detail his method of conducting screen examinations in cases of suspected stone in the kidney, and states that, in a long series of cases in which he has been able to check the accuracy of his reports, none have proved incorrect since this method of screen examination has been in use. G.

Hand Disinfect —H. J. Boldt (*The Post Graduate*, July, 1906), discusses this important subject. The ideal condition is absolute sterilisation; this, however, has not yet been obtained. The three methods most commonly used are—Fuerbringer's, by means of hot water, alcohol, and mercury bichloride; Kelly's method, requiring potassium permanganate and oxalic acid; and third, the use of chloride of lime and soda. These are all imperfect. The disinfecting power of formaldehyde is well known; unfortunately it is very irritating. Recently, however, a solution of pure formaldehyde in soap has been obtained. This demethylated saponified formaldehyde, free from formic acid, is unirritating, and is called "Veroform antiseptic." The soap being free from formic acid, and neutral, enables it to be used on the most sensitive and delicate tissues of the human body without causing harm. The results obtained by Dr. Boldt with this antiseptic have been excellent. The following technique is reliable. First, each hand, with the finger-nails cut short, should be scrubbed for five minutes with a good soft soap and hot water, which should be repeatedly changed, then each hand should be scrubbed for from three to five minutes with a solution containing two to four fluid drams of Veroform antiseptic to a pint of water, after which the hands, as desired, may or may not be rinsed in sterile water. It does not roughen the hands or harden the skin. In this and in other respects it is more agreeable than the disinfectants now in use. G.

Cholecystotomy: An Improved Technique. —Hugh Crouse (*New York Medical Journal*, September 22, 1906), suggests an improved technique for the operation of Cholecystotomy. The three methods suggested by Mayo Robson are all faulty. They are cuffing back the transversalis fascia and peritoneum, attaching these to the unopened gall-bladder, and forming by this means a fascial canal. The gall-bladder is opened through this 48 hours later. In this method the delay of 48 hours is often too long, and the difficulty in recognising the fundus of the gall-bladder at the end of this time is often extreme. In the second method the right border of the omentum is sutured to the gall-bladder and the peritoneum, and immediately incised, in this way forming an omental wall to the tube draining the gall-bladder. This method has the objection that the canal is insecure, and the danger of fat necrosis occurring in the omentum is great. The third method is that of a purse-string suture retaining the tube in the fundus of the gall-bladder, and packing round this with gauze and making a secondary gauze drain through the renal hepatic fossa. This method leaves the probability that when the tube is removed an unadherent space may remain between the gall-bladder and the abdominal wall, thus allowing the still open bladder to drain into the free abdominal cavity. The author's method of dealing with such cases of contracted gall-bladders which require drainage is as follows: the gall-bladder is dissected off from the under surface of the liver; this allows it to be brought right out through the abdominal wall. A piece of perforated rubber sheeting is then passed over the gall-bladder and carried as far down along its duct as possible. The gall-bladder can then be opened and thoroughly washed out without any danger of soiling the peritoneum. The fundus of the gall-bladder is then stitched up to the abdominal wall. This operation has proved successful in the author's hands, and avoids the dangers and disadvantages of the other methods commonly employed at the present time. G

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

KAPPA.—The Spa you mention can be reached in 19 hours from London and 10 from Paris. It stands at over 1,000 metres.

RAY.—Actinomycosis of the intestines is not very uncommon. The rectum and cæcum are the parts most affected. In 111 cases collected, in 62 the cæcum and appendix were the probable seats of the disease. The process generally terminates in intestinal fistula.

THE FIRE AT MESSRS. ALLEN AND HANBURY'S.

MESSRS. ALLEN AND HANBURY ask the hospitality of our columns to inform the profession that the general conduct of their business is in no way interfered with. The fire was confined to two large buildings used respectively for the bottling of oils and the manufacture of hospital furniture. Their warehouses, laboratories, offices, and printing department are in no way affected, and there is consequently no interruption whatever of business. Accommodation for the two crippled departments has been already provided in their own premises at Bethnal Green and at the West End.

TERMINOLOGICAL INEXACTITUDE IN MEDICINE.

THE subject of medical terminology was discussed in a lecture on Saturday by Dr. Clifford Allbutt, on "Men and Things," delivered before the Guy's Hospital Physical Society. Sir Samuel Wilks, who presided, referred to an amusing case which he had recently seen reported in a medical journal. A medical man had thought that he had before him a case of appendicitis, but found on operating that it was nothing of the kind. Instead, however, of saying that he had made a mistake, he called the case "pseudo-appendicitis."

FERMENT.—Glycogen is converted into starch by many agencies; acids, diastase, and ferments in the pancreas, liver, saliva, and blood all have this action, more or less.

S. L.—The cause of the disappearance of yellow fever in cold weather is, doubtless, the disappearance of the mosquito.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 17th.

POST-GRADUATE COLLEGE (West London Hospital).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. 5 p.m.: Lecture:—Unusual Cases of Appendicitis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. L. Mummery: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. S. Collier: The Pathology and Treatment of Cerebral Vascular Lesions.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. R. Wells:—Medicine. 3.15 p.m. Mr. M. Robson:—Surgery. 4 p.m.: Mr. Carglil:—Ophthalmology. Out-patients Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.)—5 p.m.: Demonstration:—Dr. D. Grant: Case Taking.

THURSDAY, OCTOBER 18th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens. 8.30 p.m.: Papers:—Mr. H. Spicer: Intraocular Infections. Mr. G. Coats: Posterior Scleritis. Dr. Edridge-Green: Observations on Hue Perception.

MOUNT VERNON HOSPITAL (7 Fitzroy Square, W.).—5 p.m.: Dr. J. E. Squire:—"Bronchiectasis."

POST-GRADUATE COLLEGE (West London Hospital).—2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Diseases of the Eye. 5 p.m.: Lecture:—Anæsthetics.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Mr. M. Morris: The Treatment of Some Common Skin Affections.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. G. Rankin: Medicine. 3.15 p.m.: Sir W. Bennett: Surgery. 4 p.m.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—5 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Eczema, its Varieties, Symptoms, and Causes.

FRIDAY, OCTOBER 19th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—5 p.m.: Clinical Cases. Papers.

POST-GRADUATE COLLEGE (West London Hospital).—2 p.m.: Medical and Surgical Clinics. Diseases of the Throat, Nose, and Ear. 2.30 p.m.: X-Rays. Operations. Diseases of the Skin. 5 p.m. Lecture:—Surgical Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m. Mr. S. Stephenson: Clinique. (Eye.)

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. R. Radford:—Medicine. 3.15 p.m.: Mr. McGavin:—Surgery. Out-patient Demonstrations. 10 a.m.: Surgical and Medical. 12 noon: Skin.

Vacancies.

Somerset Hospital, Cape Town.—Assistant Resident Medical Officer. Salary £200 per annum, with quarters and rations. Applications to David and Soper, Agents of the Somerset Hospital, Cape Town, 54 St. Mary Axe, London, E.C.

West Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to John H. Bonner, Secretary.

Cornwall County Asylum, Bodmin.—Second Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, washing, &c. Applications to the Medical Superintendent.

Durham County Hospital.—House Surgeon. Salary £120, with board and lodging. Applications to Wm. R. Wilson, Secretary, 68½, Saddler Street, Durham.

Saint Leonard, Shoreditch.—Second Assistant Medical Officer. Salary £100 per annum, with rations, washing, and furnished apartments. Applications to Robert Clay, Clerk to the Guardians, Clerk's Office, 213, Kingsland Road, N.E.

Bradford Royal Infirmary.—House Physician. Salary £100 per annum, with board and residence. Applications to Edmund Forster, Secretary.

Bradford Royal Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to Edmund Forster, Secretary.

Appointments.

BROWN, A. CARNARVON, M.R.C.S., L.R.C.P.Lond., Senior House Physician at the Great Northern Central Hospital, Holloway Road, N.

BROWN, ROBERT, M.B., Ch.B., Junior House Surgeon at the Great Northern Central Hospital, Holloway Road, N.

CLARK, JAMES, M.B., Ch.B., Senior House Surgeon at the Great Northern Central Hospital, Holloway Road, N.

GUNN, RODERICK M., M.B., Ch.B., B.S., Junior House Physician at the Great Northern Central Hospital, Holloway Road, N.

HARGEST, JOHN FREDERIC, M.B., C.M.Edin., District Medical Officer by the Bristol Board of Guardians.

HOLDEN, ARTHUR S., M.B., Ch.B.Edin., Assistant Resident Medical Officer at the Sheffield Union Hospital.

LONGWILL, DAVID, M.B., Ch.B.Glasg., Medical Officer of Health for Shettleston District by the Glasgow Parish Council.

LYON, GEORGE, M.B., Ch.B., F.R.C.S.Edin., Pathologist to the Great Northern Central Hospital, Holloway Road, N.

JAMES, W. T., M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the New Quay District of the county of Cardigan.

MACKENZIE, T. C., M.B., M.R.C.P.Edin., Senior Assistant Physician at the Royal Asylum, Aberdeen.

MANSON, J. S., M.B., Ch.B.Edin., Senior House Surgeon at the Oldham Infirmary.

PICKETT, JACOB, M.D.St. And., M.R.C.S., Consulting Surgeon to the Metropolitan Ear, Nose, and Throat Hospital.

PRICE, DAVID THOMAS, M.B.Lond., Medical Officer by the Shepton Mallett (Somerset) Board of Guardians.

RHIND, THOMAS, L.R.C.P.Lond., M.R.C.S., D.P.H.Camb., Medical Officer and Public Vaccinator to the Hawkesbury District by the Chipping Sodbury (Gloucestershire) Board of Guardians.

RUTHERFORD, JOHN V. W., M.B., M.S.Edin., Honorary Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

SMITH, HOYLAND, M.R.C.S.Eng., L.R.C.P.Lond., Senior Resident Medical Officer at the Sheffield Union Hospital.

Births.

EVERINGTON.—On Oct. 11th, at Cumnor, Sanderstead, the wife of H. D. Everington, M.B., M.R.C.S., of a daughter.

MYERS.—On Oct. 12th, at the residence of her parents, the wife of Charles S. Myers, M.A., M.D., Cambridge, of a son.

ORMEROD.—On Oct. 7th, at Beauchamp Lodge, Wimborne, the wife of Ernest W. Ormerod, M.D., of a son.

VIZARD.—On Sept. 28th, at Ireland Island, Bermuda, the wife of Staff-Surgeon A. H. H. Vizard, M.D., Royal Navy, of a daughter.

Marriages.

BILLSON—MOORE.—On Oct. 10th, at the Parish Church, Chalsey Berks, Charles Billson, L.R.C.P., M.R.C.S., of Hornsey, to Dora Emily, only daughter of the late Thomas Moore, of Burton-on-Trent.

WANKLYN—RAWSON.—On Oct. 11th, at St. Mary's, Carlow, William Lumb, youngest son of the late Frederic Wanklyn, of Buenos Aires, to Marjorie Josephine, youngest daughter of Edward S. Rawson, M.D., of Barrowville, Carlow.

WILLETT—CATT.—On Oct. 10th, at Duffield Parish Church, Alfred Stuart Willett, of Bolney, Sussex, third son of Alfred Willett, F.R.C.S., to Cicely Hilda, third daughter of Mr. and Mrs. C. W. Catt, of The Outwoods, Duffield.

Deaths.

COX.—On Oct. 8th, at Theale, Reading, Berks, Robert David, youngest son of the late Richard Cox, M.D.

WILLS.—On Oct. 12th, at Lunecliffe, Lancaster, Lieut.-Colonel Caleb Shera Wills, C.B., R.A.M.C. (retired), aged 72.

WIMBLE.—On Oct. 13th, at 29 South Avenue, Rochester, Florence, youngest daughter of the late Frederick Wimble, M.R.C.S.E., of East Malling, Kent.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, OCTOBER 24, 1906. No. 17.

NOTES AND COMMENTS.

A Domestic Sarsaparilla Factory.

A FEW days ago a widow was charged at Stratford Police Court with neglecting her four children. A relieving officer stated that he had never seen a dirtier woman or a place in such a deplorable condition. She had come to him at night the worse for drink, and on one occasion he found the children quite naked. A medical man testified that one child suffered from rickets and scalp eczema, while all of them were verminous and indescribably dirty. Yet the occupation carried on by the woman in this hovel was the making of sarsaparilla wine. Clearly the moral of this sordid story applies to other places than Stratford. The bare fact that such an incident is possible in our present stage of hygienic civilisation may well make us look into public health matters a little more closely. Needless to say, the purity of our food and drink supplies is of vital importance to the well-being of the community. It is no less clear that a high standard in these first necessities can never be secured without adequate powers and unceasing vigilance. Hence the desirability of insisting upon the official control of all places where articles of food or drink are prepared. This matter, it is to be hoped, will engage the serious attention of Parliament at an early date. Meanwhile there will doubtless be a "slump" in the sarsaparilla trade.

The Prevention of Consumption.

THE County Council of the West Riding of Yorkshire have taken the consumption question vigorously in hand. They have drawn up an elaborate table of means for combating and preventing the malady, and have asked every authority within their area to help in their enforcement. As a matter of fact, their attack is to be made all along the line—the only way in which tuberculosis will ever be stamped out. The old truism that a chain is no stronger than its weakest link applies emphatically to the prevention of this terrible and insidious foe of mankind. To notify and isolate cases is useless without disinfection and general education of the public. Above all, it is simple folly to spend money in costly sanatoria, and to cure a few of the better-to-do classes, while the bulk of the poor patients remain practically untouched. The ordinary out-patient treatment of consumptives is a snare and a delusion. Lastly, all our measures are futile unless we insist upon a rigorous control of farms, dairies, and meat supply.

Free Midwifery.

AT a recent inquest the City of London Coroner called attention to a case in which a woman was attended in her confinement by a medical student from Guy's Hospital. It came out in evidence that the husband earned from £2 to £3 a week, and the foreman of the jury naturally asked why a registered medical man had not been called in. The probable explanation is that the gentleman in question was human enough to prefer getting his medical attendance for nothing. A medical man from the hospital stated that enquiries were made into the means of all applicants for medical assistance, and the father stated that he had earned nothing for nine weeks owing to "ill-luck." In this particular instance, the Coroner agreed that the parents were not in a position to pay medical fees. It is well to draw attention to the maternity practice of medical schools, as its abuse in some cases constitutes a great hardship to outside practitioners. Other coroners please copy.

The Man of Many Woes.

TRULY the plight of the general practitioners is woeful. An enormous stream of poor patients is diverted from their doors to those of the medical charities. Midwifery cases are catered for by maternity charities, by hospitals, and by midwives. Bogus practitioners of all kinds attend thousands of patients suffering from cancer, consumption, nervous diseases, dislocations, rheumatism, and what not. Another vast section of the public are swindled by the quack medicine vendors. Were these and various other pernicious forms of competition brought under control, the field for medical men would be enormously multiplied, and the safety of the community proportionately increased. Public opinion shows some signs of awakening, so also does the general practitioner. But he has already spent far too much time in the preliminary yawns and stretchings. When will he really shake off this most pernicious and drowsy slothfulness and gird up his loins for action?

LEADING ARTICLE.

PLAGUE EXPERIMENTS IN INDIA.

THE enormous and shocking mortality from plague in India is a standing reproach to the sanitary administration of that empire. This mortality has been steadily increasing year after year, and has now reached the stupendous figure of one million yearly. Though asserting that such figures throw discredit on the administration, we do not mean that the Indian Government have been totally inactive, but rather that, when the disease failed to respond to their efforts in the first instance, instead of redoubling their vigour and increasing their determination, they adopted the attitude of their Oriental subjects and murmured "Kismet." In the MEDICAL PRESS AND CIRCULAR it was urged that, administrative measures having failed, although applied with vigour and in the full light of present-day knowledge, the plain duty of the Indian Government was to appoint a *cadre* of highly expert scientific investigators to examine plague in every phase, clinical, pathological, and epidemiological, till it was discovered how the disease spread, and consequently how to proceed in preventing it. True, a Commission was appointed, but its report was lame and disappointing, and though the German Commission carried matters a stage further, the point was never reached at which science could give a clear guide to the Health Department as to how to direct its energies. Thanks, however, to the initiative of the Lister Institute, Mr. Brodrick early last year issued directions for a further inquiry and placed a grant at the disposal of the Royal Society and the Lister Institute for the purpose. A fairly strong Commission was appointed, and already, within eighteen months of getting to work, it has accomplished sufficient to demonstrate that a few hundreds a year spent in experiment and thought are worth as many millions spent in blind administrative action. Although it is far too early for the Commission yet to report, it has published in the *Journal of Hygiene* a number of separate papers detailing the researches of various members of the Commission and their assistants, and these papers are not only of intense scientific interest, but they shed a new and lurid light on the epizoological characteristics of plague. It may be well to recall the facts that, though the Bacillus pestis was shown by Kitasato to be the organism of plague, and though rats were known to suffer from the disease, the method of transmission of plague from rat to man was unknown. It was recognised that when rats began to die of plague in a house that house became an infected house, and that it was difficult in the extreme, even after all the rats were dead, to disinfect it satisfactorily. Everything about the house was suspect, and the floor was the part generally fastened upon as the nursery of the bacillus, principally because it was contaminated with the excretions of rats, and its filthy condition pointed to it as an ideal nidus for infection. The other chief theory in the field was that fleas acted as intermediaries for the transmission of plague between rat and man. From time to time B. pestis had been shown to exist in the stomach of fleas living on infected rats, and it was believed even to multiply in that situation, but attempts actually to transmit infection by the bites of infected fleas were generally unsuccessful, and there remained the awkward fact—or what was believed to be the fact—that the rat-flea did not bite man. Moreover, if it did attack man occasionally, there was another hiatus when the passage of plague from man to man came to be considered. Captain Liston had done something to clear the ground on these points before the Commission arrived, but the whole subject was in an unsatisfactory and chaotic condition.

It would take us far beyond the bounds of reasonable space even to summarise here the details of the ingeniously-contrived and carefully carried out experiments of the workers on the Commission, but their chief findings we may mention, as they are pregnant with significance for the future, not only of plague, also of other infectious diseases. In the first place, they have shown conclusively that plague can be transmitted from infected rat to uninfected rat solely through the influence of fleas, and that, contrary to generally accepted ideas, the rat-flea not only does bite man, but that in plague-infected houses a considerable portion of the fleas that infest man are rat-fleas (*Pulex cheopis*). Then, by experiment, it was demonstrated that healthy animals, placed in contact with infected ones, do not contract plague if no fleas are present, even a plague-stricken female being able to suckle her young without infecting them. If, however, fleas are introduced, the uninfected animals are rapidly infected, and even if the infected animals are removed and uninfected ones placed in the cage with the fleas, they generally contract plague. Infection from the soil and infection from the air have been disproved, and the transmission of plague by means of fleas from rats to other animals such as guinea-pigs and monkeys have been shown to occur. Further trials were made to find whether the infection in plague-stricken houses resided in the floor, the air, or the flea, and the flea proved itself again to be the agent at fault, even when the houses had been "disinfected" in the usual manner. In a word, the case against the flea as the intermediate host of plague is now as clear as the case against the mosquito in malaria and yellow fever, and the energies of the sanitary department of the Government of India will probably be directed into fresh and more promising channels.

NOTES ON CURRENT TOPICS.

The Sight-testing Opticians.

AN interesting, if not amusing, position has been attained in respect to the question of the sight-testing opticians. It will be remembered that the Spectacle Makers' Company promoted a Bill last summer in the House of Lords by which powers were sought to be obtained for legalising the position of opticians as qualified to test the sight. This Bill has now been abandoned, inasmuch as the Spectacle Makers' Company have found that, according to their charter, granted by Charles I., all the members of the company must be connected with the profession (?) of spectacle-making, and must possess a practical knowledge of the art. The fact of the matter, however, is that not one of the promoters of the Bill is connected with the trade. For example, one is a

newspaper proprietor, another a banker, while others are: a public caterer, a fancy goods warehouseman, an educationalist, a shipowner, and engaged in various pursuits in the City. Under these circumstances the Spectacle Makers' Company became afraid to submit their qualifications, as spectacle-makers, to the test of Parliamentary inquiry, and hence the withdrawal of their Bill. Now comes the amusing part of the contre-temps. The optician members of the Company, not to be debarred from their sight-testing propensities, have agreed among themselves to bring a Bill before Parliament, independently of the powers that be, with the object, among other things, of enforcing the conditions of the charter—that is to say, as members of the Spectacle Makers' Company, they have determined that they will be ruled only by members of the Company who are *bona-fide* spectacle-makers. What a storm in a teacup this attitude is likely to prove to the public! Nevertheless, to what will it lead should the opticians prove that they alone, and not the bankers, toy-makers, caterers, and so forth, by whom the Company is at present governed, are entitled to be members of the Company? The position, we say again, is both interesting and amusing.

Skin for Tobacco.

The skin of the modern newspaper man, as regards things medical, is as impervious as that of the rhinoceros; nothing seems capable of puncturing it. Every six months or so he deals out some old fact, dressed up in topical guise, with an ingenuousness as refreshing as it is rare in these days of British Encyclopædias and universal knowledge-guides. Flesh-grafting, one would have thought, was as much a piece of stock knowledge as the fall of the autumn leaf; but on the newspaper man's skin the grafts have not yet taken. A rare and noble sacrifice, he tells us, was made by two paupers at Stoke-on-Trent last week, when they allowed skin to be cut from their arms to supply a deficiency in the leg of a companion. But as the Guardians voted the two heroes three months' supply of tobacco free in recognition of their brave act, we fancy they will be eagerly on the look-out to sacrifice themselves again when that period is drawing to a close. But the Stoke-on-Trent paupers are not in it with Dr. Lamar K. Tuttle, of 220, West Fifty-ninth Street, New York. The *Daily Mail* thought it worth its while to have telegraphed from America a half-column of "news" which would really be hard to beat. It is headed "Life for Life: Doctor's Heroic Cure of His Mother: Mutilated to Save Her from Disfigurement." "In return for the life his mother gave him," it runs, "the pain and suffering she bore for his sake, and all her loving self-sacrifice," this doctor "has repaid life with life, suffering with suffering, self-sacrifice with self-sacrifice." The lady in question had a severe accident, and, among other injuries, sustained some laceration of the face. In order to save her from disfigurement the son "insisted on his colleagues removing enough of his own skin to cover his mother's lacerated face and arm." One by one, forty pieces of skin were cut from his body and grafted on his mother's healing flesh "The mother," we further learn, "does not know yet the extent of her boy's self-sacrifice."

Winsley Sanatorium.

Occasion was recently taken in these columns to remark on the unfortunate state of the finances of the Winsley Sanatorium. Our comments were made in no spirit of hostility to that institution, which we have reason to believe is admirably conducted and managed; indeed, the committee and medical officers have shown much self-sacrifice and devotion in the promotion of its work. Rather we wished to point out in the first place the desirability, in laying a sanatorium scheme before the public, of not encouraging too sanguine hopes of what a sanatorium can accomplish; and, secondly, of carefully providing financially for all the requirements of such an institution before embarking on building. This particular sanatorium had the unhappy, but not very uncommon, experience of finding that the actual expenditure on its erection and upkeep considerably exceeded the estimate originally presented to the committee; but one knows that architects and builders have a way of presenting things in a rosy light at the outset, and that it is well to provide a margin for unexpected difficulties. The Winsley committee is finding, now that their sanatorium is in full working order, the support it deserves is not forthcoming; and it was recently hinted at a meeting in the neighbourhood that there were certain people who would not be sorry to see it bankrupt, in order that it might be bought cheaply by the town of Bristol. We sincerely trust that nothing so mean is intended, but that that great city will support Winsley as it deserves.

Public Mortuaries.

In some quarters, more especially in the Metropolis, a good deal has been heard in late years of the scientific value of properly conducted public *post-mortem* examinations. It is fairly obvious that a vast mine of pathological and medico-legal material lies comparatively unworked in this direction. A little consideration, however, will show that a similar remark applies more or less aptly to a great number of voluntary and Poor Law infirmaries, schools, barracks, and other huge congregations of individuals. From the peculiar circumstance of the case, it is open to doubt whether the scientific aspects of the Coroner's pathological examinations could ever be systematically utilised. His particular court is concerned in the rapid and businesslike investigation of the causes of death, and there is little time to throw away on side issues. It has been freely alleged against general practitioners that their *post-mortem* examinations are unskilled, hasty, and perfunctory. In a vast number of instances they on their side may point to a wretchedly equipped mortuary or to the absolute lack of any such place, so that the *post-mortem* has often to be conducted under degrading and dangerous conditions. It would be more to the point if coroners throughout the United Kingdom were to insist upon the provision of proper mortuaries as an elementary step

in the direction of satisfactory investigation. That obvious step would raise them in the eyes of the profession far more than the attempt to thrust so-called "experts" into a monopoly at the expense of a poor but honourable profession.

A Surgical Millennium.

MODERN Surgery has taken so many ailments out of the hands of the physician that Mr. H. G. Wells might quite reasonably base his next essay on the Millennium of universal surgical operation. If we may accept a report that recently appeared in a London newspaper, a victim of multitudinous operation lives at this day in Paris in the person of a man named Landon, who recently appeared before the judges of the Second Chamber. He had undergone no less than eighteen surgical operations, and had been trepanned three times. One is not surprised to hear that his body is a mass of scars, for most of the great surgeons have used the knife on him. He appears to have passed most of his life in prison or in hospital, and was recently sentenced by default to five years' imprisonment for theft. We are told that he has already bequeathed his skull to the Faculty of Medicine. It really seems as if Landon were as great a testimony to the marvellous resisting powers of the human frame as to the wonders of modern surgery. We are glad to know that in consideration of his many sufferings the Court reduced his sentence considerably.

Hydros.—Past and Present.

In a clever and witty recent article in the *Manchester Dispatch* "An Experienced Dyspeptic," who has evidently seen many summers and a few winters, tells of the modern hydro as he finds it. The hydro is not as it used to be. Years ago the visitor was given pale green gruel, prefaced by family prayers, for supper, and at unseemly hours slumber was broken in order that drill might be performed before breakfast. Now the hydro has become, according to the "experienced dyspeptic," a place of pleasure and a haunt of fun. "Marriages" he writes, "may be made in heaven, but the preliminaries are carried out in your modern hydro." They are gayer than hotels, in spite of the fact that the fun derives no artificial stimulus from purple claret or bubbling hock. One "sad dog" of a clergyman, whose motto appeared to be "our pleasures are not here below," proved a positive deadweight at Sunday Concerts, and though he sat through a rendering of the "Holy City," and managed to abide a recitation entitled "Grandma's Day," left incontinently after a young man had finished "You should see me dance the polka with my coat-tails flying round." Cards were produced after the concert, and bridge with pecuniary accompaniments became the order of the day. "One lady, old enough to know what she wanted to do, kept a lighted cigarette in her mouth." Tennis, bowls, and coach-rides attracted those who enjoyed the open air. "It was the Continental Sunday, except that the town band did not play and you could not take a bath." Yet there was much chapel-going, and places of worship to suit all creeds were at hand. At another spa things were not so lively, but there was plenty of open country round for "light communion between the sexes. Seats were provided." But though the attractions indoors were not sufficient to counteract the open air cure, "there was a stage on which Pierrots sang and pirouetted, and revival meetings in a tent where the inhabitants groaned with pleasure." We can only say that for people who like such places, they are just the sort of places they are likely to want.

"Dr. Hawkins, M.D., U.S.A."

WEEK by week the public are being supplied with object lessons as to the worthlessness of the quack medicine trade. We are glad to acknowledge the suddenly awakened activity of the police in this important matter, on the principle of the old tag, "Better late than never." At Brighton they have secured the committal for trial at Assizes of the two Hawkins, father and son, on a charge of obtaining money under false pretences by means of powders called "Gloxiensis" and "Corrassa Compound." The composition of these cure-all remedies was stated to be bromide of potassium and other drugs costing a few pence, whereas they were sold at something near a pound. One point in this case may be commented upon generally. There is no attempt to deny that the defendants traded under the names of several clergymen and of "Dr. Hawkins, M.D., U.S.A." Now it is clear that anyone claiming to practise medicine in this country under that title would have to prove his possession of a recognised degree, and would be bound by the rules of the profession in England. Why should a man be permitted to sell medicines claiming to cure palpitation of the heart and a number of other specific affections under a fictitious name, and therefore a fictitious American qualification? Perhaps the General Medical Council might investigate this point, even if it be a little outside the strict letter of their constitution. It certainly affects the working value of the *Register*.

Holmes and Semmelweis.

IT would appear as if the tardy honour received by Oliver Wendell Holmes on account of his discoveries regarding puerperal fever is likely in some degree to diminish the fame of Semmelweis. It is natural, therefore, that a countryman of the latter, Dr. Győry of Buda-Pesth, should think it right to distinguish between the works of these two great men. He points out, without in any way diminishing the merits of Holmes, that the discoveries of Semmelweis were not merely in advance of the views of Holmes, but were in a certain way opposed to them. Holmes fought for the position that puerperal fever is a contagious disease; Semmelweis proved that puerperal fever and pyæmia are essentially the same process, or, to put it in modern phraseology,

that puerperal fever is a form of sepsis. We know now that both were right, though we do not, with the stricter contagionists, regard puerperal fever as specific. In Semmelweis' time, however, the gap between the two views was a wide one, and Semmelweis devoted much of his later writing to combating the contagionist view. It is a psychological fault that the public is in the habit of tagging to any great advance in science some one name, forgetting that discoveries are rarely sudden or the work of one man. It does not take any of the honour from Lister that he was preceded by Pasteur. Neither is Semmelweis' merit the less in completing the edifice of which Holmes had laid the foundation, and of which long before Holmes, Gordon of Aberdeen had mapped out the lines.

A Return to Vitalism.

Sir James Crichton-Brown touched on many interesting topics in his discursive address to the Leeds School of Medicine last week, but he himself seemed to think most important his criticism of the materialistic school of physiology. There is little doubt that the medical student, and, though to a much less extent, the practising physician, tend towards a materialistic view of the universe. In chemistry and physics and such studies we are accustomed to deal with matters which receive sufficient explanation on the basis of a materialistic theory. There are many things in life which cannot be so explained, but as they are not forced on the attention of the medical student, he is liable to overlook them. Sir James Crichton-Browne's protest against the application of materialistic theories to physiology is therefore not misplaced. He emphasises the immense difference between a living cell and a dead crystal, and he points out that no chemical process yet known can start a living process. No mixture or combination of elements can make live protoplasm. It is possible that Sir James protests a little too strongly, and that he is hasty in assuming that because the beginnings of life have so far escaped notice, they will always remain unobserved. Nevertheless, he is right in maintaining that when chemistry and physics have said their say, there yet remains much unexplained. It is, of course, of no avail to call such unexplained matters "vital phenomena," unless the phrase be regarded as a statement of ignorance. In the present stage of our knowledge, we must leave the explanation of such matters to speculation, but it is well to delimit as accurately as we can the field of speculation from the realm of science.

Pharmacists for the Army.

There is no doubt that there has been just cause for dissatisfaction as to the status and capability of the pharmaceutical service of the Army. This became most marked during the late war, when it was due, at least in part, to the fact that in their anxiety to obtain a sufficient number of dispensers, the Army authorities were not very particular in their choice. As a result, a number of pharmacists, broken down in health or unfit for ordinary civilian work, found their way into the service. It is proper that the subject should in time of peace receive full discussion, as the onset of another war would otherwise find things in much confusion. Surgeon-General Evatt, already well-known as an energetic reformer, has come forward with a scheme which, whether accepted or not, is likely to do good by giving a centre for discussion. He urges that there should be established a reserve of fifty pharmaceutical officers, who should, in war time, do duty in the larger military hospitals These gentlemen should be commissioned officers ranking as second lieutenant, lieutenant, captain, or major. There should be only one major, who should be commanding officer of the corps. They should, while on reserve, do a certain period of duty in a military hospital each year, so as to train them in military discipline and the routine of the service. Surgeon-General Evatt suggests a reserve fee of £25 a year, and pay during war service of ten shillings a day for second lieutenants, and so on in proportion. We are not sure that the officers of the Royal Army Medical Corps would welcome the establishment of a separate corps of commissioned officers whose quasi-independence might prove misleading, but no harm can result from a fair discussion of Surgeon-General Evatt's scheme.

PERSONAL.

Dr. Fred Carter, who has been in practice at Billericay for the long period of forty-four years, has been presented with an address and a handsome testimonial by his many patients and friends.

Professor Flinders Petrie, F.R.S., will deliver the seventh Annual Huxley Memorial Lecture before the Anthropological Society of Great Britain and Ireland in the Civil Service Commission Theatre, Burlington Gardens, at 8.30. p.m., November 1st, on the subject, "Migrations."

The Board of Governors of the Norfolk and Norwich Hospital recently presented an illuminated address to Mr. Charles Williams, F.R.C.S., on his resignation after thirty-six years' service as honorary surgeon to the Institution.

It is announced that the name of Dr. W. T. Parker Douglas, of Speen, Newbury, has been placed on the Commission of the Peace for the county of Berks.

The Harveian Oration at the College of Physicians was delivered by Professor Osler last week. The subject was "The Growth of Truth."

A bazaar will be held in aid of the Maternity and District Nurses' Home at Canning Town on December 13 and 14. Princess Henry of Battenberg has graciously promised to perform the opening ceremony.

Mr. John Humphry will shortly complete his fiftieth year of service as Medical Superintendent in charge of the Bucks County Lunatic Asylum, and the Visiting Committee of the asylum is inviting subscriptions to a testimonial to mark the public sense of his able and conscientious discharge of duties "which have been performed to the entire satisfaction of the committee, to the advantage of the county, and with uniform kindness and consideration for the unfortunate patients under his charge."

A CLINICAL LECTURE
ON
SURGICAL ASPECTS OF TUBERCULAR PERITONITIS. (a)

By FRANCIS J. STEWARD, M.B., M.S.Lond., F.R.C.S.Eng.

Assistant Surgeon to and Surgeon-in-Charge of the Throat Department, Guy's Hospital, Surgeon to the Hospital for Sick Children, Great Ormond Street.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—Before going on to the surgical aspects of tubercular peritonitis and its clinical manifestations, which I mean to discuss together, I think I shall perhaps clear the ground by dealing with some of the pathological points, and also with the question of surgical treatment and its rationale.

With regard to the pathology of tubercular peritonitis, the disease begins either as general miliary tubercle all over the peritoneum, or as local tubercular disease attacking, say, the Fallopian tube or the appendix, and gradually spreading from that primary focus. The great majority of cases are of the miliary form. The onset is generally rather acute as regards the development of tubercles, though not always as regards symptoms.

The tendency, in tubercular peritonitis, is towards the production of one or more varieties. There are three main varieties which it is important to remember. The first variety is what is generally spoken of as the ascitic form of tubercular peritonitis, in which the main symptom really is the production of ascites. The belly becomes distended with fluid, and the inside of the peritoneum is studded with little grey tubercles. Secondly, there is the form known as the plastic variety, and this may in certain cases be an early form of the ascitic, in which there is a certain amount of plastic lymph and a smaller amount of thicker fluid than in the ascitic form, and again the peritoneum is studded with tubercles. The parts which become chiefly affected are the omentum and the mesentery. The omentum in a child, for instance, instead of being quite thin, may be several inches in thickness. I shall presently show you a case illustrating that. The third variety that one sees is the caseating form, which is possibly the later form of the second or plastic variety, and in which there is a great tendency to the formation of adhesions and caseating foci. The intestines get stuck together and studded with caseating tubercles, and the walls become softened. Because of the caseation you get little loculi of pus and these often communicate with the intestines. In short, the whole abdominal cavity becomes a mass of adhesions and loculi of caseating material and fæcal matter. Very frequently, also, external sinuses or fistulæ develop, particularly at the umbilicus. If you see a child who is very ill, and has got a swollen abdomen and a red patch or sinus at the umbilicus, you may be certain that it is suffering from tubercular peritonitis. Another variety which I might mention is really a result of healed tubercular peritonitis, the fibrous form, in which there is no active tubercular disease but as a result of previous tubercular disease fibrous tissue is formed, and practically the whole of the abdominal contents become matted together and converted into a solid mass. This condition of things is liable to give rise to intestinal obstruction.

Just a word with regard to the surgical treatment, and I am not going to deal with any other form of treatment except the surgical; though, of course, I do not want by any means to suggest that there is nothing to be done in tubercular peritonitis but to operate. First, I may mention the fact that the real value of simple laparotomy in cases of tubercular peritonitis was discovered accidentally. In cases of mistaken diagnosis laparotomy was performed for some other disease, or for diagnostic purposes, and tubercular disease was found. Nothing was done, and the abdomen was closed up, and the patients rapidly got well. It was these mistakes, leading to the patients getting well, which really started the practice of operation for cases of tubercular peritonitis. Nobody knows how it is that the patients are so greatly benefited by laparotomy, especially in the plastic and miliary and ascitic forms of the disease. It seems most likely that the admission of light or air, or both, into the abdominal cavity produces some influence upon the disease process which tends to arrest it.

With regard to the final results of laparotomy, in cases of tubercular peritonitis, different observers give different percentages, but all agree that in nearly all cases the patients improve for a certain time. Rouel collected 358 cases in which laparotomy had been performed, and he found that 75 per cent. were either improved or cured. Watson-Cheyne gives 50 per cent. as improved or cured. Treves says that 35 per cent. are cured, and many are improved. Considering that a very large proportion of cases of tubercular peritonitis go downhill rapidly if not operated on, I think that these figures form a very strong argument in favour of surgical treatment.

From a *clinical* point of view, it is important to remember that tubercular peritonitis is quite an extraordinary disease in the many ways in which it develops. The cases that I am going to describe to you will illustrate that very well, and also, I trust, help you to realise that in any difficult case of abdominal disease that you have to tackle, you should always ask yourself the question, "Is this tubercular peritonitis?" By doing this, you will find that very often you will avoid a mistake.

This boy that I now show you was in Clinical ward, and was operated on on the 27th of February, 1905. As you will see, his abdomen is its normal size. It was enormously distended, owing to very marked tubercular peritonitis of the plastic variety. As it is more than a year ago since the operation was performed, and he appears to be quite well, he may, I think, be considered to be cured.

We will now consider some other cases. I have tried to divide the cases up into different groups. First, there is the *acute form*, which is frequently diagnosed as some disease differing altogether from tubercular peritonitis. I will first describe the case of a woman, 22 years of age, who was admitted into Clinical ward on July 12th, 1903. The notes state that she complained of severe pain in the abdomen. She was taken suddenly ill five days before admission with acute pain all over the abdomen. The pain was followed by sickness, and the symptoms got daily worse until the time of admission. When I saw her she was very ill, cold, and collapsed, her pulse was 120, and she was incessantly vomiting. Her abdomen was rigid and boardlike all over, and did not move on respiration; it was also tender, but more tender below than above the umbilicus. From the signs and symptoms we judged that the case was one of acute general peritonitis due to appendicitis. The only dubious point about the case was that whereas patients, three or four days after the onset of peritonitis, usually have a subnormal temperature, she had a temperature of 102 degrees. I operated, making an incision over the appendicular region, and, instead of finding that she had appendicitis, I found that she had the plastic form of miliary tuberculosis. All the peritoneum on the intestine, mesentery, and omentum, and down into her pelvis, was studded over with myriads of tiny tubercles. There was also a little fluid. The appendix was not affected at all, and I did not remove it. We put stitches

(a) A Clinical Lecture delivered at Guy's Hospital, Friday, May 25th, 1906.

into the abdominal wall, and put the patient back to bed. Her temperature came down, and all her other symptoms disappeared, and at the end of three weeks she left the hospital well. Only a short time ago I heard that she is still quite well.

The next case was a child admitted into Clinical ward about the same time as the last case. She was admitted for acute pain in the abdomen, vomiting, a tender, rigid abdomen, and she was also passing blood from her rectum. It was thought that, as she was passing blood, she might have intussusception or peritonitis. But she was so excessively ill that I did not think she would be able to stand an operation, and no operation was done. She was put to bed and given salines and strychnine, and she slowly but gradually improved—so much so that she was sent away to a convalescent home. Now comes the interesting point. That child was re-admitted three months afterwards with a fistula at the umbilicus and, obviously, well-marked tubercular peritonitis. These two cases serve very well to illustrate the *acute form* of the disease.

We now come to the second group, which is perhaps more commonly met with. In this group of cases the disease is not usually recognised very soon, because its onset is very insidious. The patient does not seem well, the bowels are irregular, he loses flesh, the temperature is sometimes up and sometimes normal. But one feature which stands out is that, while the patient loses flesh generally, he gradually develops ascites. I will read you some of the chief points about a case which will illustrate that very well. A young woman, aged 16, was admitted, under Dr. Pitt, on June 15th last year. A month before admission the patient had pain in the upper part of the abdomen, which began to swell, and gradually became more and more distended. Her bowels were irregular, she had profuse sweating, night and day, and lost flesh. When admitted, her temperature was raised to 100-101 degrees every day practically, and she had well-marked ascites. After she had been in some little time, and had not improved, I was asked to see her, and strongly recommended operation, feeling sure that she was suffering from tubercular peritonitis. Twelve days after she came in I operated. The patient was given an anæsthetic, and I made an incision three and a half inches below the umbilicus. The peritoneum was found to be thickened, and on opening it, some fluid escaped. Tubercles were found on the peritoneum, and some of them seemed to be caseating. There was also some lymph on the intestines. This was, then, a case of the ascitic form of tubercular peritonitis, and it seemed as if the disease was advancing, because some of the tubercles were apparently caseating. The temperature came down soon after the operation, no re-accumulation of fluid took place, and the patient went out on July 23rd. She returned again at the beginning of this year with a stitch sinus. There was no sign of any return of the disease, and she is to all intents and purposes perfectly well, and looks a different girl.

Here is another case of the ascitic form. A child, æt. three, complained of pain a month before admission. His mother noticed that his abdomen was swelling. He had more or less severe attacks of pain every day which made him scream. His bowels had kept regular, but the motions were loose. The abdomen continued to increase in size, and the patient was noticed to be short of breath two days before admission. At the time of admission the abdomen was tender and distended, dull in the flanks and resonant in front. The evidence of ascites increased rather than diminished. After the patient had been in for some little time, I saw him and recommended that an operation should be performed. He had been admitted on November 29th, and a laparotomy was done on February 1st of this year. A tremendous amount of fluid escaped, and the peritoneum was studded with small grey tubercles, a few of which showed evidence of caseation. The patient had no re-collection of fluid, and did well from that time, and went out on March 31st. He is up here again to-day, and you will see that he is quite well. So much for the ascitic form. Both of these cases, as we saw, had a lot of fluid. Other cases, however, in which the onset is slow and insidious, do not get ascites, but some other form of tubercular peritonitis.

I had such a case at Great Ormond Street recently, a child, æt. five, who for four months had been ill. He was very thin, his skin was dry, and he had a big, distended abdomen, but no evidence of fluid. It was thought that he had probably got tubercular peritonitis. He was not expected to recover, because he was so extremely ill and wasted. But, in view of the unexpected cures that do take place after laparotomy, I decided to operate. I opened his abdomen and found the intestines matted together by masses of adhesions, and there were numerous loculi full of caseating tuberculous material and pus, and owing to the action of the bacillus coli the pus stank like an appendicular abscess. I had to be extremely careful to avoid tearing holes in the infiltrated intestines. Very soon after the operation the intestine gave way in several places, fæces poured from the abdominal wall, and the child very soon died.

In the third group I have put down *cases resembling typhoid*. Four years ago I operated on a very interesting case of that kind. A boy, æt. seventeen, was in the South-Eastern Fever Hospital, and was thought to have typhoid. A month afterwards it was decided that he was not suffering from that disease, and he was transferred to Guy's and placed under the care of Sir Cooper Perry. He was found to have a distended abdomen, his temperature was uniformly high—103 degrees or 104 degrees—and he had signs of fluid in the abdomen. I was asked to see him, and decided to operate. Under cocaine anæsthesia, I opened the abdomen and found that the peritoneum had tubercles all over it, and that his omentum and mesentery were enormously thickened. He had also a fairly large amount of fluid, which was let out. The wound leaked for some days, but eventually healed, and the patient went out apparently quite well and weighing 2st. more than when he was first brought in. That was four years since, and he was up here a year ago quite well. I mention that case to show you how very important it is, when you have doubtful cases of typhoid, to think of tubercular peritonitis.

We now come to another group—those *cases which resemble appendicitis*. In this group comes the case of the boy whom I showed you a few minutes ago. He had been ill a month. His illness began quite suddenly, so that it was really an acute case. He had been playing at football, and on the following day he was taken ill, had pain over the appendix area, and vomited several times. The pain continued off and on for three weeks, and three days before admission he returned to bed with pain over the same area, and a temperature of 101°-103°. There had been no constipation, but rather a tendency to diarrhœa, and no vomiting since the attack a month before. When the patient was admitted his abdomen was found to be full, but moved well, excepting over the appendix area, which was tender to touch and slightly rigid. There was also bulging into the anterior wall of the rectum. Although we thought he had appendicitis, yet we were struck by the fact that he looked remarkably well for a child who had been suffering from appendicitis for over a month, and this feature of the case determined me not to operate at once, but to keep the patient under further observation. The temperature, on the second day after admission, was 101·4 degrees, and after going down a little rose to 102 degrees. Five days after admission it was 103·8 degrees, and the patient seemed more ill. On the following day I operated, and found some coils of intestine adherent to one another and to the anterior abdominal wall. On passing the finger into this part of the abdomen between the coils, a certain amount of blood-stained serum escaped—two or three ounces. The cæcum was free, and so was the appendix, but the omentum was enormously thickened with tuberculous growth, which we thought at first was a great mass of sarcoma. The wound was closed, and from that time the patient steadily got well, and he has been all right

ever since. That shows how closely a case of tubercular peritonitis may resemble appendicitis.

The last group of cases that I want to mention to you are cases in which the disease is *causing intestinal obstruction*. A woman, æt. nineteen, was admitted under Dr. Taylor, on November 16th, 1901. From May to September she had had continual headaches, and her eyes were bloodshot. She was given some medicine, and this cured her headaches and her eyes became better. On October 22nd she vomited and had pain across the abdomen. The abdomen became distended, and the patient suffered from constipation. Beyond these symptoms there was nothing definite made out by examining her abdomen. She was given enemata, but it became more and more difficult to get her bowels opened. Her abdomen got increasingly distended, and eventually she began to vomit. Dr. Shaw, one night, asked me to see her. He diagnosed intestinal obstruction, and advised operation. Accordingly I operated, making an incision from just below the umbilicus to the pubes. Enormously distended coils of intestine were found, and the peritoneal surface was seen at once to be studded with small tubercles. Two of the most distended coils were punctured, and a large quantity of gas and fluid fæces escaped. The cause of the obstruction was then found to be at the site of the appendix, which, as the result of the tuberculous disease, had become partially adherent to the mesentery, so forming a band beneath which a loop of small intestine had passed and become compressed. The appendix was removed, the wound was closed, and the patient was but back to bed. This then was a patient who had intestinal obstruction and also tubercular peritonitis. I removed the obstruction, but nothing was done for the peritonitis, and the patient went out perfectly well six weeks afterwards.

I have got notes of one other case of obstruction caused by tubercular peritonitis, but it is a case of a different type to the last. Here the obstruction was not due to the actual presence of tubercular peritonitis, but to dense adhesions which were the result of a cured tubercular peritonitis. The patient was a man in Stephen ward under Dr. Beddard. He had a very long history of constipation, and when he came in it was quite obvious that he was suffering from intestinal obstruction. He was constantly vomiting, and neither enemata nor drugs had had any effect. I operated, and found that practically all his intestines were tied up into a solid mass by fibrous adhesions. There were kinks and numerous patches of distended and twisted gut. I opened some of the coils of intestine and let out the fluid, and sewed the holes up again, but practically no good could be done, because the bowel was kinked everywhere, and the man died two or three days afterwards. This case illustrates the way in which a cured tubercular peritonitis may produce obstruction.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by R. F. Tobin, F.R.C.S., Surgeon to St. Vincent's Hospital, Dublin., on "Urethral Impediments to the Evacuation of Urine." Lecture delivered to Senior Students at St. Vincent's Hospital.*

AT Selkirk School Board on October 15th, it was reported that several children had been examined on account of the recent outbreak of diphtheria in the town and out of 41 so examined, 8 were found to have bacilli in their throats. Out of another batch of 78, 12 were found to be affected, and the fear was expressed that when others were examined other cases would be reported. No fewer than 60 were absent from one school that morning. It was curious that although bacilli were found in the throats of the children, there was no sickness

ORIGINAL PAPERS.

THREE CASES OF UTERINE FIBROIDS OF UNUSUAL INTEREST (a).

BY F. BOWREMAN JESSETT, F.R.C.S.,
Senior Surgeon, Cancer Hospital, Brompton, etc., etc.

Case I.—UTERINE FIBROIDS—CALCIFICATION—CŒLIOTOMY—FIBROIDS REMOVED—RECOVERY.

S. J., widow, æt. 51, no family, was sent to me by Dr. Frazer, of Brighton. Admitted into Cancer Hospital on September 15th, with the following history:—

History.—About seven months ago health failed, and suffered pain in left side of back, radiating down left leg, with a feeling of contraction in the leg when walking. The pain steadily increased, and difficulty in walking became more pronounced, until now she can get about only by using a stout stick. Bowels regular, and no difficulty in micturition. No vaginal discharge. Climacteric two years ago.

Previous History.—Ten years ago left breast was removed by me at the Hospital for Scirrhus. There was no recurrence for three years, when she presented herself again with recurrence in axilla. This I removed, and a third operation was performed in the same axilla after another three years. Since this operation, four years ago, there has been no recurrence.

Present Condition.—The woman looks pale and ill, with anxious expression of countenance. Has been steadily losing flesh during the last few months, complains of constant pain in her back, and difficulty in walking. Abdominal examination reveals little; the abdominal walls are flaccid, and no enlargement, but by deep pressure over the uterus there is some resistance, and pain is accentuated. Per vaginam the os and cervix uteri are found to be somewhat hard, but not enlarged. Bimanually, a large, somewht irregular lump can be felt in the right fornix, which is evidently connected with the uterus. The fundus of the uterus is prominent, and several hard nodules can be felt connected with it. Uterus is quite mobile.

On September 18th I performed cœliotomy, the patient being placed in extreme Trendelenburg position. A hard nodular tumour the size of a cricket-ball readily came in view, pedunculated and fixed to the right corner of uterus. On withdrawing this the attachment to the uterus tore through, although only slight traction was made. I transfixed the pedicle, and ligatured it. Three other smaller growths were brought into view attached to the posterior surface of the uterus. By dividing the peritoneum over them they were readily enucleated, the bleeding being arrested by deep catgut sutures, and the peritoneum carefully closed over.

Another larger growth the size of a hen's egg was found on drawing the uterus out of the wound, situated on the posterior surface of the organ. This was enucleated in a similar way to the others, the capsule being stitched with catgut.

The abdominal wound was closed in layers, the peritoneum united with catgut, then four silkworm-gut sutures passing through all the tissues excepting the peritoneum acting as supporting sutures; then the aponeurosis was united with continuous sutures, and the skin also by a continuous suture, the four silkworm-gut supporting sutures being finally tied.

Ten days after the sutures were removed, and patient has made an uninterrupted convalescence.

Remarks.—This case is of interest on account of the relative absence of symptoms leading one to suspect the presence of fibroids of the uterus. There was no enlargement of the abdomen, no interference of the functions of the rectum or bladder, and no hæmorrhage. In fact, the patient applied only on account of the pain in the left side of the back and pains down the leg, which caused her to walk with great difficulty. When she consulted Dr. Frazer he, on examination, discovered something in the pouch of Douglas, and sent her to me, as

(a) Cases shown and notes read before the British Gynæcological Society, London, October 12th, 1906.

I had operated on her on previous occasions for carcinoma of the breast, and it was feared there might be some secondary growths in the pelvis.

The case also shows the advisability of in all cases examining the pelvic organs when women complain of pain extending down the nerves of the leg, as no doubt the pressure of a tumour on the sacral and lumbar plexus must often be responsible for these pains, and if these are not discovered any amount of local or general treatment will be of little avail in relieving the patient of her symptoms; whereas if a tumour or growth is discovered, and can be removed, the patient is at once relieved of her symptoms, and enabled to enjoy life again.

The case is also of interest on account of the calcification which has taken place in the tumours. They are, as you see, entirely calcified, and it is comparatively rarely that such a condition exists. They are usually present in elderly women, some years past the menopause. When occurring before this the tumours are always, I believe, as in this case, either subperitoneal or pedunculated subserous growths, in which the means of nourishment are extremely slender. In elderly women all varieties of fibromyoma are liable to calcification, and may exist in either of two forms—peripheral or interstitial. In the former and rarer variety a thin, rough, chalky deposit is found on the surface of the growth only; in the latter, there is an infiltration of lime salts throughout the thickness of the growth, which may be localised in patches, or invade the whole mass. Where peripheral calcification is complete, the centre of the tumour usually becomes necrotic from complete arrest of its circulation.

The calcified tumours have been known and described so long ago as Hippocrates and other ancient authors. One of the largest calcified tumours, described as weighing 2lb. 5½oz., is now in Edinburgh Anatomical Museum, and was found in a grave within the pelvis of an apparently elderly woman.

The case is further of interest on account of her having had carcinoma of the breast, which had been removed ten years previously, and that although she had had recurrence on two occasions, she had been free from such recurrence for at least four years.

I have at present under my care another similar case, in which I removed a large fibroid tumour several years previously, and where I had removed the breast for scirrhus. In my practice I have only had very few such cases, so that the coincidence of fibroids following carcinoma cannot be very common, and probably is of no significance, although it has been stated by some authorities to be so.

Case II.—Case of Severe Menorrhagia—Fibroid of Fundus—Vaginal Hysterectomy—Recovery.

E. L., widow, æt. 49, seven children. Admitted into Cancer Hospital, September 15th, 1906.

History.—Enjoyed good health until about a year ago, when she complained of general weakness and debility. Had always been quite regular, not excessively so, up to this time, when menstruation became irregular and fitful, sometimes losing excessively. She took little notice of this, thinking it was "change of life." She would be quite free from any loss perhaps for six weeks at a time, then a severe loss of blood would occur, lasting on and off perhaps for a month, passing at times large clots. These attacks have become more frequent lately, coming on often quite suddenly, until now she has become pale and weak, and more or less a confirmed invalid. Suffers slightly from constipation.

Previous History.—Never suffered from any severe illness; a big-framed woman, and been accustomed to work until present illness.

Present Condition.—Pale, anæmic appearance; pulse, want of tone; complains of general lassitude and disinclination to do anything. The abdomen is soft and flaccid. No tumour can be felt. Per vaginam, the walls are lax, and a quantity of leucorrhœal discharge. In Douglas' pouch a good-sized tumour can be felt, smooth and apparently fixed. The os was soft and papulous, the lips thick, and a finger could be almost passed. I took the lump in the pouch of Douglas to be a retroverted uterus. By firm pressure it could be pushed upwards to the brim of the pelvis. Bimanually, this was found to be enlarged and smooth.

The question of diagnosis was not altogether easy, as the menorrhagia might be caused by one of three conditions—viz., uterine polypi, submucous fibroid, or carcinoma of the fundus. I gave it as my opinion, however, that it probably was caused by a submucous fibroid.

On September 18th she was anæsthetised, and placed in lithotomy position on the operation table. The uterus was readily drawn down through the vagina with Vusellum forceps, and I dilated the canal up to 21 Hagar. Owing to the great length of uterine cavity, digital examination revealed nothing. I decided to remove the organ, which was readily done in the usual way.

The patient made an uneventful convalescence. On cutting open the uterus a fibroid the size of a walnut was, as you see, found in the fundus uteri close under the mucous membrane, and was the cause unquestionably of the hæmorrhage and the retroversion.

This case represents one of a number of cases which have been under my notice in which patients have been allowed to go on for months and years continually losing large quantities of blood, and becoming anæmic and useless members of society, spending a large part of their time in bed, being dosed with ergot, iron, and other drugs without any good effect. At the end of the period, which usually lasts a week or ten days, they get up, only to repeat the same process in a week or two's time. The diagnosis is, as in this case, not always easy, as the loss may be caused by several different conditions; but in all such cases I consider a most careful examination of the uterus should be made, and if nothing is discovered by ordinary digital examination or by the speculum, the patient should be placed under an anæsthetic and her uterine cavity dilated and explored, and if no polypi be found, the uterus had better be removed. I have seen many cases in which women have been suffering from severe menorrhagia, in whom the uterus has been curretted, often several times, without any good accruing. At last, by full dilation and exploration a submucous fibroid has been found, and in some cases fairly readily removed, and the patient's symptoms relieved.

Case III. is one of peculiar interest. It is a case which I was asked to see by Dr. Wickham, of Fleet, to whom I am indebted for the following:—

Notes.—E. H., married, æt. 46, eight children, youngest 2½ years old. Instruments used at confinement on two occasions, always convalesced well after confinements, being up and about in a fortnight.

Has never suffered from leucorrhœa. Urination normal until present illness, when about a month previous she thought she noticed she had to pass water more frequently than usual. Menstruation regular.

Remembers seven years ago after one of her confinements having an attack of severe vomiting, accompanied by great abdominal pain, which lasted twenty-four hours, but left no bad results, and she was quite well in a day or so.

Last May (four months prior to present illness), had a severe attack of abdominal pain, no vomiting. This only lasted for twenty-four hours, and she was able to get about again the following day.

Present Illness began five weeks before Dr. Wickham saw her, with pain in abdomen, which rapidly became worse, accompanied with vomiting during the night; this subsided. She was given an opium pill, which kept her comfortable the following night. Next day she was seen by her doctor, who found the abdomen a good deal distended and tender on palpation. Temperature 102, pulse 100. Bowels had not been open since the beginning of the attack. A large enema was administered, but produced but little effect. She then took, on her own initiative, a dose of castor oil, which caused vomiting the whole night. A large turpentine enema was given and bowels were copiously relieved, and the distension of abdomen disappeared. The temperature, however, remained high, never falling below 100-101, for the next two days. A vaginal examination at this time revealed the os uteri slightly pushed forward, and a smooth elastic swelling could be felt

in the pouch of Douglas. At this stage Dr. Wickham asked me to see the patient with him; the swelling in pouch of Douglas had increased somewhat.

The abdomen was somewhat distended, and a distinct sense of resistance could be defined below the umbilicus. Bimanually this fulness was well marked, and evidently was one with the fulness in Douglas' pouch, which felt elastic and doughy. Fluctuation could not be made out. The patient complained of very little pain, and the examination did not cause her any great distress.

The question of diagnosis was difficult and obscure. We were disposed to think it might be a soft, rapidly-growing fibroid, or an ovarian cyst which was suppurating. It was decided, however, that an operation should be performed as early as possible.

On the following day, September 16th, assisted by Dr. Wickham, Dr. Wilcox giving the anæsthetic, I opened the abdomen between the umbilicus and pubes, when the intestines were found to be matted together, and extensive peritonitis present. In separating a coil of small intestine which was somewhat firmly adherent to the brim of the pelvis, a quantity of badly smelling pus welled up. This was carefully wiped away, and seemed to be localised to a pocket, at the base of which a considerable rounded swelling was seen filling the pelvis, the peritoneum over which was coated by a thick coating of lymph. I cautiously tried to free some of the other coils of intestine, but found them very firmly adherent, and being afraid of breaking into the swelling in the pelvis, which I was pretty sure contained a quantity of pus, I approximated the wound in the abdominal parietes by means of pressure forceps, and had the patient drawn to the bottom of the table and placed in lithotomy position, and then with a fine aspirating needle explored the swelling by puncturing it, when pus was withdrawn. I then with a bistoury made a free opening into it, and evacuated a large quantity of most foul-smelling pus. I made a very free opening into it, and wiped it out with gauze, and with the douche washed the cavity out, and then introduced a large drain of iodoform gauze.

The patient having been replaced in the prone position on the table, I again examined the abdominal cavity, and finding no sign of any pus, placed a drain of iodoform gauze on the lower angle of the wound, and closed it in layers. The temperature steadily fell, but remained somewhat high for the first week, when there was a sudden large escape of pus, through the abdominal wound evidently, and another pocket formed by the intestines.

The patient made an excellent convalescence, and is now—nearly a month after the operation—free from any discharge, and the wound in the abdomen firmly healed.

I venture to think this case is one of considerable interest and importance, both from a diagnostic point of view as well as to the best method of treatment.

What the cause of this abscess was it is very difficult to say. Whether it was caused by perimetritis, cellulitis, or a suppurating ovarian cyst, or could it be one of those cases of appendicitis in which the appendix became adherent to some of the pelvic viscera, becoming perforated and thus forming the abscess, it is difficult to say. Even at the time of the operation it was impossible to make out without breaking down the intestinal adhesions and freeing them from the pelvis, which proceeding I think would have been fraught with considerable danger to the patient.

With respect to the best operation to be performed in these cases, I should be glad to have the views of some of the Fellows of this Society. In the first instance I was disposed to explore the swelling in Douglas' pouch through the vagina with an aspirating needle, when of course I should have discovered pus and opened up the abscess cavity and drained; but then what about the two pockets of pus which were disclosed around the intestines by the abdominal incision? I am quite certain they were not connected directly with the abscess in the pouch of Douglas, and if not, clearly the patient would not have materially benefitted unless they opened later into the abscess cavity connected with the vagina.

Then, with regard to flushing the abdomen, I was asked why I did not. My reply was, we have the pus now limited to the cavity from which it had been wiped, whereas if I flushed the cavity out some of the pus cells might be carried to other parts of the abdomen which are at present uninfected. I should very much have liked to have examined the appendix, but I think I acted in the best interest of our patient by not venturing to disturb the adhesions which nature had apparently placed there to protect the other parts of the abdomen from infection.

I should have mentioned that in the first instance on which Dr. Wickham saw the patient the abdomen was much distended, and symptoms of some intestinal obstruction, which he feared might occur, were present; but after the administration of a large turpentine enema, the bowels were freely relieved, and the distension disappeared.

THE IMPORTANCE OF THE EARLIEST POSSIBLE RECOGNITION OF MALIGNANCY IN TUMOURS (a).

By FRANK T. PAUL, F.R.C.S.,

President of the Liverpool Medical Institution; Surgeon to the Liverpool Royal Infirmary, &c.

The author drew special attention to the diagnostic value of the microscope, and said that in dealing with new growths two mistakes were frequently made, either of which was sufficient to bring about a failure in treatment: one was waiting in the early and doubtful stages until malignancy was declared; the other was throwing the responsibility of the diagnosis on a pathologist who had never seen the case and had only a shred of tissue on which to base his opinion. If it was intended to ask a pathologist to make the diagnosis, he should also be asked to see the patient. Histology alone was not sufficient in difficult cases; either the clinician should be better trained in histology, or the pathologist should become a clinical pathologist. Most medical men had seen cases of cancer become hopeless whilst waiting under drug treatment until a certain diagnosis should be arrived at and an operation recommended. It was a small matter to snip off a papule or sore from the tongue or to excise a nodule from the breast in order that the necessary information might be quickly obtained. In spite of all that had been done by the brilliant band of workers in Cancer Researches, up to the present early and complete removal had proved the only reliable cure. Recurrence meant incomplete removal—though it was true that in some people the tendency to cancer was so inveterate that the cure of one growth might be followed by the development of another of a different type.

Discussing epithelioma of the tongue, the President said that he associated himself with Mr. Butlin in believing that it was curable, under favourable conditions. The early diagnosis could only be made with the help of the microscope. The difficulty generally lay in the differential diagnosis of epithelioma, papilloma, simple and tubercular ulcer. Epithelioma often began in syphilitic tongue, and it was to be feared that many lives were lost owing to the delay caused by the six weeks' specific treatment it was usually

(a) Abstract of Presidential Address delivered before the Liverpool Medical Institution, October 11th, 1906.

thought necessary to prescribe, while the microscope would often reveal in a specific or apparently simple ulcer a small centre of malignant disease. Butlin's radical operation was not too extensive for the smallest epithelioma of the tongue. Solitary tubercular ulcers of the tongue or lips might occur in apparently healthy subjects, and without microscopical examination be mistaken for epithelioma. Papillomata should be invariably removed, and if found to be undergoing malignant changes an extensive dissection should be performed, although the papillomatous form of cancer, because of its outward growth, was much less malignant than the ulcerous variety. Apparently innocent growths of the mouth were better snipped off and examined, if only to relieve the mind of the patient. Speaking of malignant disease of the maxillary antrum, Mr. Paul said that a reference to his note-books showed him that 20 or 30 years ago sarcoma was more common than carcinoma; he thought carcinoma was attacking younger people, whilst sarcoma was diminishing in frequency. Microscopic examination of fluid drawn off by the exploring needle, although the fluid might appear to be nothing but blood, occasionally enabled the surgeon to make a diagnosis of malignant disease. The value of the microscope was further shown in the diagnosis of cancer of the cæcum from appendicitis. Mr. Paul then discussed the varieties of fibromata, malignant and benign, skin tumours, implantation cysts and rodent ulcers. The latter disease was a true cancer of the sebaceous glands, was often multiple, and, contrary to the statement often made, it did occasionally infect the lymphatic glands. At its commencement rodent ulcer had to be differentiated from minute cysts and adenomata, from warts, moles, and epitheliomata. Complete removal (when possible) was more valuable than X-ray treatment.

The author then related a case of extensive epithelioma of the perineum, which he thought originated in an included remnant of epiblast in the mesial line. Carcinomata often began in imperfectly removed sebaceous cysts. The old idea that parotid tumours were always innocent was not correct, and growths which were at first innocent often became malignant. Salivary carcinoma was as malignant as breast cancer. Malignant diseases of the bladder and of the breast were then discussed, Mr. Paul's well-known views on the pathology of the latter being re-stated, and the importance of early microscopical examination in doubtful cases of disease of either organ insisted upon.

The address was illustrated by 71 lantern slides taken from Mr. Paul's micro-photographs.

THE DIAGNOSIS OF SOME FORMS OF DYSPEPSIA (a).

By WM. G. BARRAS, M.D., C.M., D.P.H.,

Hon. Physician to the Elder Cottage Hospital; Bacteriologist to the Borough of Govan, Glasgow.

Dr. Barras pointed out that, normally, the stomach occupies the left hypochondrium, the epigastrium, and part of the right hypochondrium, but as five-sixths of it are situated in the left hypochondrium, it follows that much the greater part lies to the left of the middle line. Part only of the stomach wall is to be found just under the abdominal parietes, viz., that in the epigastric region. The pylorus is level with the tip of the ensiform cartilage, in the right sternal line, and it, with the lesser curvature of the stomach, is covered by the left lobe of the liver, whereas the fundus is covered by the left leaflet of the diaphragm and lower anterior part of the left lung.

The tympanitic note of a normal stomach should cease about one inch above the umbilicus.

The term indigestion should be limited to cases where there is no organic or functional disease present, the cause of which is to be found in the food, which may be abnormal in quality or quantity. The importance of thorough mastication can scarcely be over-estimated, as bolted food is a fruitful source of indigestion. Improper arrangement of meals is another fruitful source of dyspepsia. Dr. Barras condemned the tea habit after meals, and what are called appetisers. Excess and defect in the supply of food leads to pathological conditions. Dr. Barras, in speaking of neurasthenia, said that, in that malady, we are dealing with poisoned and not simply with exhausted nerve centres, and pointed out the evils that may arise from constipation, the tea and tobacco habit in this connection. Agreeing with Dr. Herschell, Dr. Barras stated that in primary hyperchlorhydria, we have an excess of pepsin and hydrochloric acid, but secreted only at the normal digestive periods, and ceasing in the intervals, thus distinguishing it from hypersecretion. This condition is said to account for a fourth of all the so-called indigestions, and the greater part of all acutely painful dyspepsias. The common symptom present is, at first, uneasiness after meals, then, as the case advances, pain is commonly present two to four hours after a meal, and can be relieved by a large dose of alkaline medicine. In hypersecretion, the worst paroxysms are usually experienced at night. The patient may complain of cramps in the epigastrium and left mammary region some time after meals. The introduction of a meal of food relieves for the time being, by absorbing the acid. In anæmia, pain is not so severe and appears sooner after a meal. In ulcer, again, the pain often begins at once, on the taking of food, and is relieved by vomiting.

The neuroses of the stomach were discussed, paresis of the pylorus leading to diarrhœa. In hyper-excitability, we may have eructations, regurgitation of food, spasm of the cardiac or pyloric ends of the stomach, leading to a feeling of great distension, the patient being unable for a time to dispose of wind either upwards or downwards. Further, nervous vomiting may ensue. Dr. Barras cited a case under his care where a young lady had persistent vomiting of food without any obvious cause, which was relieved when she took rest in bed. She has been under medical care for a year, but no recognised method of treatment has done any positive good. Her loss in weight has not been serious. Dr. Barras referred to a case of bulimia, related by Reyer, where a lady, 32 years, after a long period of worry and trouble, was suddenly attacked with hunger, and within an hour consumed three pints of milk, 23 eggs, and two pints of wine, after which she fell asleep, and on waking was perfectly well. The presence of hydrochloric, in cases of ulcer of the stomach, was contrasted with that generally found in cancer, namely an absence of hydrochloric acid, with an excess of lactic acid. Dr. Barras concluded his interesting address, by discussing the question of gastric neurasthenia.

(a) Abstract of a Presidental Address delivered Oct. 17th, 1906, before the Glasgow Eastern Medical Society.

CLINICAL RECORDS.

VENESECTION IN URÆMIA.

BY W. E. WATERS, L.R.C.P. & S.I.,
Medical Officer, Carbury Dispensary District.

ON the 6th inst. I had a case of uræmia in a girl æt. 22, which had grown worse since the day before, in spite of ordinary treatment. I could not gather from the history how long there had been albuminuria, but on this day the urine was loaded with albumen and very scanty. She had intense headache and constant vomiting of quantities of bile; pupils widely dilated, and total blindness—she could not even see where the window was. She had occasional hallucinations, but was rational between them. Temp. 102, pulse 110. No pulmonary œdema. Respiration normal. Seeing there was no time to lose, I took 18 ozs. of blood from the arm. There was not any decided improvement that night or next morning; so I then (24 hours after the first bleeding) removed another 18 ozs. of blood. She soon appeared better, and from that improved so rapidly that on the 10th inst. there was not a trace of albumen in the urine, and she felt quite well, except for the natural amount of weakness.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Multiple Gummata of the Tongue.

By T. P. LEGG, M.S., F.R.C.S.

AMONG the out-patients was a married woman æt. 37, who presented herself suffering from two ulcers on the dorsum of the tongue. She stated that these had been present for some weeks, that they had caused very little pain, and that they had begun as small lumps in the substance of the tongue. On examination, there was seen to be a deep ulcer with sharply-cut edges on the right of the dorsum to the right of the middle line, and round the ulcer there was a good deal of thickening. On the left side of the tongue at its posterior part there was a second smaller but otherwise exactly similar ulcer. The bases of the ulcers were quite smooth and covered by a yellowish slough. The tongue as a whole was considerably enlarged, its margins were indented by the teeth, and the papillæ had disappeared over the greater part of the dorsum, the epidermis being thickened, with the characteristic appearances of chronic superficial glossitis. There was no interference with the mobility of the tongue, which could be fully protruded. The mouth was in a filthily dirty condition, there being many septic stumps in both the upper and lower jaw. The glands on the left side of the neck in the submaxillary region were considerably enlarged; they were not tender or painful. Under the treatment they diminished in size as the condition in the tongue improved.

As far as the past history was concerned, the only evidence pointing to syphilis was the fact that she had had three miscarriages. The diagnosis of the condition was obviously multiple gummata. Mr. Legg said that the case illustrated how extensive the disease may be without in any way interfering with the mobility of the tongue, thus offering a marked contrast to carcinoma, where even a small mass or one limited to half the tongue will produce great interference with the movements of the organ. The next point the case illustrated was the importance of the septic condition of the mouth in many of these cases, and the necessity of getting rid of this factor by local treatment. Hence it was advisable to remove all decayed stumps, to insist upon the regular use of a toothbrush, so as to cleanse the gums and the teeth. Mr. Legg also thought that the local application of a mercurial preparation such as glycerine of perchloride of mercury, 1 in 2,000, would be of great value, in addition to the internal administration of iodide of potassium. In some cases, he said, where the tertiary symptoms do not yield to iodide of potassium, one finds that mercury administered internally in small doses will be of benefit, and the *hydrarg. cum creta*, in the form of a pill *bis die*, is one of the best preparations to employ. Whether the enlargement was a gummatous condition or one due to sepsis was not quite certain, but Mr. Legg was inclined to the former view. He mentioned also that he had had a similar case in a younger woman who presented herself on account of having two or three round lumps in the substance of the tongue; each lump was elastic and about the size of a Barcelona nut. The patient volunteered the information that these lumps had been present some months before and had disappeared under treatment by iodide of potassium; there was no doubt that the lumps were multiple gummata. There was no glandular enlargement. In the course of a fortnight under iodide of potassium all that remained of the gummata was some slight thickening at the site of each of them. In this case, as there was no ulceration, no local treatment was adopted except keeping the mouth clean. Provided this is done in all cases, Mr. Legg pointed out, a very rapid improvement takes place. It was important, however, to impress on the patient the necessity of continuing the treatment after the local manifestations of the disease have disappeared. This treatment would consist in gradually dropping the mercury in those cases in which it had been administered and continuing the iodide of potassium for from three to six months.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

CASE OF CEREBRAL ABSCESS.—MR. JOSEPH CUNNING operated on a man, æt. 32, who had been admitted on account of severe headache, which had been going on for a week. For 10 years the patient had suffered from discharge from the left ear, which had ceased when the headache began. He had been under the care of his doctor during this time, and the night before the operation he had been sent to the hospital. On admission his temperature was 102, and although he had severe posterior headache, there was no tenderness over the region of the mastoid. The pulse was 100, and there were well-marked signs of chronic otitis media. On the morning of operation he developed further signs: slight drowsiness and a slow pulse rate varying from 64 to 74. There was no paralysis, but the left knee-jerk was considerably increased; other reflexes were apparently not altered. Before operating, Mr. Cunning remarked that there were distinct signs of increased intra-cranial pressure, as exemplified by the slow pulse rate, for in all other conditions, when a patient is as ill as this man, the pulse rate would be increased to 100 or over; next, the drowsiness was another symptom pointing to the same condition. The only other sign of pressure was the increase of the knee-jerk on the left side. As the patient was suffering from chronic otitis media, the present condition was, Mr. Cunning remarked, almost certainly a complication of that disease, and a collection of pus was probably what would be found. There was no evidence, however, as to the situation of the pus, whether it was in the cerebrum, cerebellum, or outside the dura mater. The eyes of the patient had been examined, and no optic neuritis had been found, but as this symptom was an unreliable one in respect to diagnosis, no great weight could be attached to its absence. Lateral nystagmus, which was usually a late symptom of pressure, was not present. He pointed out that, although there perhaps might seem insufficient reasons for

operating at this stage, yet those who had most experience of intra-cranial abscess knew that by the time the diagnosis has become easy and undoubted, the patient was generally beyond the reach of surgical aid. The patient was anæsthetised with chloroform by the house physician, Miss O. B. Smith, and Mr. Cunning pointed out that chloroform was the better anæsthetic for these cases, as it produced less congestion about the brain than ether, and he considered that the anæsthetic should be administered very lightly to this man on account of the risk of respiratory failure. He then said a few words about his plan of procedure, which was to begin by opening the mastoid antrum in the hope of discovering the direction taken by the pus; if no indication were found in the antrum or middle ear, then to trephine by separate openings so as to expose in turn the temporo-sphenoidal lobe and the cerebellum, these being the situations in which an abscess was most likely to be found. The mastoid antrum was then opened, and the bar of bone between the antrum and middle ear removed. It was then found that the tegmen tympani which formed the roof of the antrum was absent, having been destroyed by the disease. On passing a scoop through the opening thus left, a large abscess cavity, containing about two ounces of green and extremely fœtid pus, was entered and evacuated. Two drainage tubes were then put through this opening into the abscess cavity, which was then gently irrigated with saline solution. The ends of the tubes were then stitched to the lower part of the skin incision, dressings applied, and the patient sent back to bed. Mr. Cunning remarked on the wisdom of always exploring the antrum and middle ear to begin with. Though it was unusual for an abscess to be evacuated in this position, yet if one can do so, it undoubtedly was the best method, as the drainage of the abscess was through its most dependent part, and the surgeon has not to go through healthy brain-substance to reach it, as he would have to do by trephining. Another reason was that in a case with any serious complication of mastoid disease, thorough clearing out of the mastoid cavity must anyhow be effected, otherwise the patient would still be liable to further complications. He pointed out that it was always found that, in these cerebral abscesses, organisms (usually bacillus coli) producing a foul smell were present, as was exemplified in the present case. It was by no means certain, he thought, that the patient would eventually recover, although the abscess had been found and opened, as the pus sometimes extended to the descending horn of the ventricle even after the abscess had been evacuated.

It is satisfactory to state that a week after operation the man is free from headache, and able to sit up and talk to his friends. The drainage tubes are still in situ.

TRANSACTIONS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting Held Thursday, October 12th, 1906.

Mr. F. Bowreman Jessett, President, in the Chair.

Dr. Macnaughton-Jones: Specimen of necrobiotic fibroid shown, and notes read by Dr. Harry Overy.

This tumour (shown) was removed from a patient æt. 39, and was accidentally discovered, as she never suffered from any pain or discharge, and her periods were regular and not excessive; she complained of feeling the abdomen distended and of passing urine with some difficulty. When I saw her the tumour distended the abdomen on the left side and reached to the umbilicus. On exposing the tumour, the protrusion at its left side was found to contain fluid which, on evacuation, proved to be disintegrated blood of a coffee-ground colour. The wall of the cavity was covered with soft semi-purulent exudation protruding into the cavity, evidently the necrobiosis had not been of recent occurrence. The central portion of the growth was very hard and thick, but nearer the necrobiotic cavity become œdematous. It would appear to me that infection did not reach from the uterine cavity, but that there had been a telangiectasis of portion of the tumour, and secondary breaking down of the tissue after hæmorrhage.

Dr. Cuthbert Lockyer examined the growth and reported that it was not malignant. The clinical history is interesting in the complete absence of any symptoms caused by the tumour, which must shortly have ruptured with probably a fatal issue. The patient made a complete recovery.

Dr. J H. Dauber: Specimen of necrobiotic fibroid, with notes. In July, 1905, saw a patient in consultation. She was æt. 40, single, and had been suffering acute pain for two or three years. Three weeks previously she had a sharp attack of pain while stooping over her housework, and had to take to bed. When he saw her the temperature was 101°, there was subacute peritonitis, and a tumour arising two or three inches above the umbilicus. On vaginal examination, another tumour was felt in Douglas's pouch. She was removed to the Hospital for Women, Soho Square, for operation. Upon opening the abdomen the tumour exhibited was found, which was a fibroid springing from the fundus of the uterus, with a twisted pedicle. There were many adhesions to the intestines, which were readily separated when the pedicle was transfixed and tied off. The uterus contained two or three fibroids, and was removed by supravaginal hysterectomy. The tumour was offensive, spongy, and dark, with contained blood. It would probably have become gangrenous, and caused the patient's death. It seemed to be a fibroid in which some change had taken place, such as twisting of the pedicle or infection from the bowel, and required immediate operation.

Dr. Heywood Smith understood there was some oozing in the case after operation, and wished to know whether any means were taken to stop it by adrenalin, and if drainage was used.

Dr. R. T. Smith proposed that Dr. Macnaughton-Jones' specimen should be referred to the Pathological Committee. It seemed to have been a very acute process, and there seemed to be nothing in the symptoms to account for it, such as rise of temperature, nor any indication of gross change. There may have been albuminuria to account for the lesion. In reference to Dr. Dauber's case, the symptoms exactly tallied with those of twisted pedicle in an ovarian tumour. It was very rare to have twisted pedicle associated with fibroid, or to see a fibroid with such a small pedicle.

Dr. W. H. Slimon seconded the proposition, which was agreed to.

The President said it was not uncommon for a pedunculated fibroid to get twisted. He thought most of the cases of gangrenous fibroid were due to calcareous change, interfering with the blood supply.

Dr. J. H. Dauber considered there might have been a twisted pedicle and consequent interference with the blood supply.

Dr. Harry Overy said he had noticed that in large fibroids hæmorrhage was found when examined microscopically. Whether the fibroid was pedunculated or not, the centre of the tumour showed early degeneration, even when to the naked eye it looked homogeneous throughout, and the microscope showed red blood-cells among the tissues in the centre.

Dr. J. H. Swanton said in Dr. Dauber's case there

was pyrexia and a history rather of gangrenous fibroid than necrobiotic. On section of a necrobiotic fibroid there was a soft liquefied centre which was caused by an infiltration of watery fluid, and more or less liquefaction of muscular fibres. In the specimen shown, there seemed to be no evidence of liquefaction having occurred.

Dr. J. H. DAUBER said the hæmorrhage was easily controlled, and he did not employ any drainage. He very rarely did drain, even in septic cases, and he had never had cause to regret it. He did not know the definition of necrobiosis was as narrow as stated. It was considered at the hospital to be a case in which necrobiotic changes had taken place.

The PRESIDENT showed a specimen from "A Case of Multiple Pedunculated Fibroid of the Uterus, with Calcareous Degeneration, removed by Cœliotomy and Enucleation of the Tumours" (which will be found in full on page 438 of the present issue).

Dr. F. A. PURCELL said he regarded the last case narrated as interesting, owing to the history of successful removal of the mammary glands some years previously being followed by calcareous degeneration in the fibroid tumours of the uterus.

Dr. HEYWOOD SMITH said the interest of this case consisted in the disease which arose in the uterus separated by ten years from the cancerous condition of the breast. He contended that the two diseases in this case were quite independent, but he was not sure that the fibrous condition of the uterus was not the primary cause of the mischief. One did not know how those fibroid tumours arose, but they were probably from uterine trouble. There were not sufficient cases to allow a generalisation, but the course of events seemed to be that the uterine irritation from the presence of the fibroid set up irritation in the breast, and from that carcinomatous degeneration arose. He believed there was no convection of the disease, but that the irritation took the form of cancer. He believed the fibroids occurred prior to the formation of cancer of the breast. The fibroids were small at first, and did not seem to have developed for many years afterwards.

Mr. HOWELL EVANS said one point of interest was the fact that the patient had malignant disease of the breast, and survived eight years. While possessing that condition of malignancy that there should be subsequently discovered a condition of natural protection in the way of calcification in a tumour which was recognised as being innocent. What was the state of that scirrhus of the breast? Was it one in which the fibroids and the calcareous tendency was extremely marked, and would consequently have given perhaps one of the rare occurrences of Nature's expulsion of a malignant tumour? If so, there was present an individual factor in a patient who showed a tendency to protection against malignancy. Apart from the question of any association with cancer of the breast, he had seen, in the practice of one or two gentlemen who had a great number of cases passing through their hands, three cases during the last three years of calcification of fibroids, and the small degree of symptoms was noteworthy. Unless they happened to be cervical or submucous, they had given rise to few symptoms. Was it possible to learn anything about the life history of fibroids from these calcifications? Patients came before the medical man at the age of 21 to 30, with symptoms which no gynæcologist was able to impute to fibroids. In five or ten years, or even longer, those patients might appear with a crop of fibroids, which more resembled the tuber of a potato than anything else. A fibroid might lie relatively dormant for many years, and then suddenly burst out, so that there was a crop of tumours. He asked whether any member of the Society could throw any light on the relation which bands of fibrosis or calcification in fibroids bore to the life history of fibroids.

Dr. J. H. DAUBER said he could see no relation between the carcinoma of the breast and fibroid disease of the uterus. It was common to find uterine carcinoma in conjunction with fibroids. With regard to calcification of fibroids, he had always looked upon calcification as a sign of the long duration of a fibroid.

Mr. CHARLES RYALL said the subject of enucleation of the tumours had always been a question of interest to him, as to when one should enucleate fibroid tumours of the uterus. There were some cases upon which enucleation should certainly be tried. In such cases as the President's, where there were calcareous fibroids, he regarded it as excellent treatment. Fibroids such as those just described had passed their days of growth and were undergoing calcareous degeneration. In his experience calcareous degeneration was not very common in fibroids. With regard to enucleation, there were certain cases of fibroid of the uterus in which he thought enucleation was desirable, cases where the condition of the fibroid somewhat approached calcareous degeneration—namely, where there were one or two hard fibroids of the uterus, especially in young women. He did not think it was justifiable to remove the uterus from a comparatively young woman where she had a very hard single fibroid. But where they were multiple, hysterectomy was certainly the proper treatment to carry out.

Dr. J. H. SWANTON wished to know the condition of the ovaries. In patients with calcified fibroids who submitted themselves to operation the chief symptoms complained of were pressure symptoms and uræmia, but otherwise there were very few symptoms. He would also like to hear about the mortality of the operation for the removal of fibroids, as Piquand's statistics of 175 cases showed a very high mortality compared with that of fibroids generally, namely, as much as 12%, against one of 3%-5%.

The PRESIDENT, in reply, said he had removed the ovaries on several occasions as a kind of last resort in cancer of the breast, but had not seen any improvement whatever follow. He had very little doubt that the fibroid in question had been of long duration, and only when it became calcified and pressed on the pelvic nerves, causing a radiating pain down the legs, was attention drawn to it. He agreed that the calcification of fibroids was an evidence of their long duration. He could not say whether calcification of the cancer in the breast was found. He had seen few calcified tumours of the uterus, and he was rather astonished to hear that Dr. Dauber had seen so many. With regard to enucleation, he agreed that generally it was bad practice to enucleate uterine fibroids, because there were probably more interstitial fibroids in the uterus than could be found on external examination. When subperitoneal calcified tumours were found at the age of this woman, he did not think there was any chance of further trouble, and therefore he enucleated them all. They came out easily, and there was no difficulty with hæmorrhage. In some of the deeply seated interstitial fibroids of the uterus there was considerable difficulty in stopping the hæmorrage. The ovaries were small, but quite healthy, and were not removed. He had very little doubt that if this woman's fibroids had not become calcified she probably would not have been troubled with any pain whatever. He could not say what was the mortality after operation in these cases, as he had not a sufficient number of cases on which to form an opinion.

The PRESIDENT then showed a specimen from "A Case of Severe Menorrhagia with Retroversion of Uterus and Intramural Fibroid in Fundus. Vaginal Hysterectomy" (which will be found on page 439 of the present issue). He said that in connection with this there was another specimen which he removed a week later, and was interesting, because he doubted the diagnosis. The patient was a woman æt. 36, who had had a miscarriage about two months before coming in, and she had had constant hæmorrhage more or less ever since. When she was admitted she had a foul-smelling discharge coming from the uterus. On passing the sound into the uterus, hæmorrhage was very free. He formed the opinion in that case that

she had carcinoma of the fundus, so he removed the uterus, and had brought it up for inspection. She made a good recovery. The pathologist informed him that it was a piece of placenta.

Dr. R. T. Smith desired to know whether the President would have removed the uterus if he found the growth on examining with the sound, or used a snare after dilatation.

Mr. Howell Evans said with regard to the question of menorrhagia, that he agreed with the President in saying that when the menorrhagia was marked there seemed to be little short of hysterectomy to relieve the condition. There was a true scientific treatment of all cases of menorrhagia. One observed the patient for a short time and might adopt a palliative method, but the point was to recognise not by the quantity lost alone, but by the condition of anæmia. If the patient at each successive period lost more blood than she ought to, as shown by the blood count in the intermenstrual period, that patient was losing ground, and the more she lost ground the less use she had for an organ which had an abnormal and irregular function, and one had to decide between removal of that organ as a useless organ and the preservation of the individual as a useful member of society.

Prof. R. J. Kinkead (Galway) said he thought the last speaker had gone too far. He had in his mind half a dozen cases in which there was marked menorrhagia, continuing for a long time, and in some of which, when they came into hospital under his care, they were in a condition of profound anæmia. One case showed the difficulty of diagnosing submucous fibroids. She was over 56, and he curetted her four times. He examined the uterine cavity with his finger, but could find no evidence of fibroid at all. She came in again suffering from menorrhagia. He then dilated the cervix uteri, and on that occasion he found a polypus which he could touch. He removed it with an écraseur, and found it to be the size of a goose egg. It must have extruded since he operated before. She was now healthy and resumed her ordinary occupation. He had recently had under care a series of cases of persistent menorrhagia for which he felt he could have done nothing. There was nothing wrong except that there was a natural want of contractile power. Curetting was of no use. But he found that by steadily applying iodine and phenol to the inside of the uterus the patient recovered. The last case was that of a woman who had been married twelve months and had miscarried. She was sent to the hospital from the Union. He went to the hospital a few hours after her arrival, and the hæmorrhage was more profuse than he had ever seen before. He had to plug the uterus, but she was now perfectly well, after treatment with iodised phenol twice a week for two months to the uterine cavity. He opposed removal of the uterus for hæmorrhage in all cases.

Dr. C. H. Bennett said he had had a considerable experience of menorrhagia, but he had not heard a word that evening with regard to treatment of it in the shape of medicine. All that had been discussed had been operation. He had had some bad cases of menorrhagia which had been considerably relieved and eventually stopped by giving 10-grain doses of gallic acid. Under that treatment the cases had soon got very much better, and the flow had eventually ceased altogether. If he had another case of the kind he would try that before suggesting any operation, unless of course it was clear that there was some fibroid or polypus present to cause the bleeding.

Dr. F. A. Purcell pointed out that the medical side of the matter was not being discussed. It was the common practice to treat cases of menorrhagia by other means before deciding to operate; such things as sulphide of calcium or tincture of hydrastis or the tincture of any astringent were employed.

Mr. C. Ryall remarked that it was notoriously easy to be wise after the event, but on looking at the specimen as brought forward, it seemed to be more a matter for dilating the cervix than for hysterectomy. It looked as if it could have been enucleated and the organ put back again. The first and most important treatment for the condition was rest. The patient might be put to bed and given all sorts of drugs, but it was the rest which did the good. Where reasonable treatment was carried out and was found to be of no avail, and where no tumour could be detected, the organ was functionally useless, and not only so, but it was a source of danger.

The President, in reply, said it was impossible to get a snare round it. It was submucous, and more or less interstitial.

The President, continuing, said it was a very large uterus, about three and a half inches in length. The top of the uterus could not be reached, and therefore it could not be ascertained whether it was a submucous fibroid or a fibroid at all. At all events, the finger could be introduced far enough in to make sure that there was no polyp. If that could have been found the polyp would have been removed and the uterus saved. But he thought the result would probably warrant what he did. She was a poor woman, with seven children, and the living of those seven children depended upon her efforts, as she was a widow. It was true he might have given her a pint or two of gallic acid and kept her in bed, a treatment which might have stopped the hæmorrhage, but his impression was that all the gallic acid in the world would not stop it, because she still had the fibroid, and she would have lost the chance of getting her living and that of her children. Therefore he contended it was far better to get rid of a useless organ, and allow the woman to have a chance of recovering her health and strength, than to delay for months with the bare chance of doing her good. He fell in with the remarks expressed by Professor Kinkead, and he had not only used iodised phenol, but had found fuming nitric acid more useful. If one dilated the uterus in some of the cases of simple endometritis with general thickening of the mucous membrane, then by curetting and applying fuming nitric acid, relief would follow. It was a more beneficial treatment than the application of iodised phenol. It was necessary to pack the vagina with carbonate of soda solution to prevent burning of the vagina. But the patients had no pain afterwards. It caused no discomfort. But in such a case as that now under discussion, where no cause for the condition could be ascertained, the treatment was to remove the uterus.

The President then read the notes of "A Case of a Large Abscess in Douglas's pouch simulating a suppurating Ovarian Cyst causing Bowel Obstruction." (This is published in full on page 439 of present issue.)

Dr. Smallwood Savage took it that a case which definitely showed pus in the pelvis should be opened per vaginam. But there was a certain class of case in which it was most difficult to diagnose pus, either acute salpingitis or a case of extra-uterine gestation. The operation in either of those cases would necessarily be by the abdominal route. He did not think he could follow the President when he said he did not think the vaginal operation would have been successful. He thought probably it would, because pus would always follow the line of least resistance, and if one had made a line of least resistance by doing a posterior vaginal cœliotomy, one would be producing a track which the pus would follow and come down by the vagina, except for that which collected in little pockets.

The President, in reply, said he was still in doubt as to the origin of this pus. But the history pointed to appendicitis. Four months ago she had severe pain and vomiting. Five weeks before operation she had severe abdominal pain and vomiting, which lasted for twenty-four hours. With regard to opening the vagina, he did not think those pockets in the abdomen would have discharged into the vagina. About a week after the operation she had a sudden rush of pus through the abdominal wound, probably from another pocket of pus. He was very much

afraid of pulling the intestines about, because he thought that if he did he would make the patient's condition very much worse.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, OCTOBER 16TH, 1906.

PRIESTLY SMITH, F.R.C.S., President, in the Chair.

MR. GEORGE COATS read a paper on

POSTERIOR SCLERITIS, AND INFARCTION OF THE POSTERIOR CILIARY ARTERIES.

He referred to the first description of this condition by Fuchs in 1902, and to cases probably similar reported by Knapp, Wagemann and Salzer. Only two such cases had been submitted to pathological examination. In his own case the disease was not diagnosed during life, as the eye when first seen was already disorganised by iridocyclitis.

On dividing the globe, a peculiar round area 10 mm. in diameter was found above the papilla, in the form of a brown island, surrounded by a broad yellow moat or gutter. Within this area, the inner third of the sclera, and the whole thickness of the choroid and retina were completely necrotic. There was no inflammatory thickening of the necrotic patch, but a moderate round cell infiltration of the living tissues. The other changes in the eye were due to iridocyclitis and secondary glaucoma.

Mr. Coats pointed out that the amount of necrosis was out of all proportion to the inflammation, so that there must have been vascular obstruction. The necrosis was more extensive in the retina than in the choroid, and in the choroid than in the sclera, and this corresponded to the usual wedge shape of the infarction. The affected area would correspond to the distribution of one of the larger posterior ciliary vessels, and these vessels had but scanty anastomosis with each other. The changes in the retina were closely similar to those found in the rabbit after ligature of the ciliary arteries, and in man after optico-ciliary neurotomy. The surrounding chronic inflammation was similar to that found in non-infective infarctions elsewhere, and the chronic iridocyclitis was probably of the same nature, due to the diffusion of toxines of low virulence into the vitreous. There was some evidence of vascular obstruction in two of the other reported cases.

MR. HOLMES SPICER read a paper on

METASTATIC AFFECTIONS OF THE EYE.

The first case was that of a young man who had a sudden attack of pain in one eye, with obliteration of the central part of the field of vision. He was in good general health, except for a large crop of boils on the buttocks from rowing at Cambridge. On examination of the eye three days after the attack of pain, a brilliant green mass was seen springing from the centre of the disc; it was round, sharply defined, and had no appearance of structure, such as hooklets. Its appearance suggested a parasitic cyst. It continued to grow, and was making the patient very ill. It was lacerated with a needle under ophthalmoscopic guidance, but it only contained some cloudy opaque material like pus. The eye was enucleated.

The swelling was found to be an abscess in the substance of the retina, having in its centre a large mass of staphylococci. The patient made a rapid recovery in health.

The second case was also that of a young man, who had had a large boil on the neck, and was suddenly seized with pain in one eye, with loss of sight. He had well-marked phlebitis of the retinal arteries in one eye and slightly in the other. After prolonged treatment one eye got well, and the other became quiet with loss of sight. Two years later it became acutely inflamed and was then enucleated. Although very seriously ill at the time, he recovered promptly after removal of the eye, showing it to be the only part affected.

The third case was also that of a young man, who had retinal phlebitis, followed by local keratitis profunda after a serious attack of diarrhœa and ptomaine poisoning.

The fourth case was one of diffuse exudation on the surface of the choroid, invading slowly nearly the whole of it and producing in places detachment of the retina. This also occurred in a young man suffering from a large crop of boils on the neck. Treatment by anti-staphylococcal injections was commenced, but he refused to continue it.

DR. EDRIDGE-GREEN read a paper on

OBSERVATIONS ON HUE PERCEPTION.

These observations were made with an instrument by means of which the exact size of a portion of the spectrum which appeared monochromatic was ascertained, when it was isolated from the adjacent portions. Hue perception was found to be most accurate in the blue and yellow regions, though in most it was more accurate in the yellow region. Then there was a gradual diminution towards the centre and ends of the spectrum. Green came next, then violet, and lastly red. These facts were in accordance with the author's theory of colour perception, and were predicted by it, namely that the colour perception of different individuals varies with the development of a colour-perceiving centre in the brain, that those with a greater development of this centre see more colours (points of difference) than those with a less development, and that colours appear in a regular order at the successive points of difference in a straight series.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD OCTOBER 11TH, 1906.

DR. ALEXANDER MORISON read a paper on the

CARDIO-VASCULAR STATE IN ASPHYXIA NEONATORUM, AND ITS MANAGEMENT.

He adopted the usual classification of these cases into the cyanotic and pale varieties, regarding the latter as a more advanced stage of the former, and proceeded to discuss the underlying physiological and pathological conditions in the two varieties.

In discussing prognosis he regarded the condition of cardiac action as the best guide to a forecast, and stated that asphyxia under these circumstances represented the etymological origin of this term—namely, *pulselessness*, the prognosis being favourable in proportion to the vigour of cardiac action. The more remote consequences of asphyxia neonatorum were then discussed, and he considered that many of the certified causes of death in early infancy, such as hæmorrhage, atrophy, convulsions, and atelectasis, bore a direct relation to asphyxia neonatorum.

In considering treatment he discussed the question of dividing or not dividing the funis immediately after the birth of the child, and stated that only in the cyanotic variety was it advisable to allow the funis to bleed for a short time. He then considered the methods of artificial respiration, and remarked that recent anatomical investigation and physiological conceptions of cardiac action justified a prolonged effort to resuscitate the stillborn infant, as pulsation of the auricles might continue after the heart had ceased to be heard beating, and might provoke ventricular contraction even after the case appeared to be hopeless from general signs.

DR. LONGRIDGE stated that at Queen Charlotte's Hospital they considered that the "blue" baby and the "white" baby resulted from totally different conditions. The former was the result of asphyxia, and the proper treatment was to clear out the pharynx and perform artificial respiration. The latter was due to shock, and pulsation in the cord was usually absent. The proper treatment was a hot bath, gentle stimulation, and massage of the heart. Artificial respiration was unsuitable.

MR. T. HERBERT HERRING then read a paper on

EASY METHODS OF STERILISING URETHRAL INSTRUMENTS,

giving a practical demonstration of the methods. He considered that cystitis was most commonly due to

the employment of septic catheters or bougies. The use of a catheter was entrusted to anyone, the instruments were often not efficiently sterilised, the lubricant more especially was a frequent cause of sepsis as usually applied, and efficient cleansing of the operator's hands was neglected. He had therefore devised a method of sterilisation of catheters by which both the catheter and lubricant were sterilised, and little manipulation of the catheter by the operator was required. The catheter, or series of catheters, were suspended from hooks in a cylindrical metal vessel containing water and a small quantity of vaseline. The water was then brought to the boil by a spirit lamp underneath, and the catheter sterilised, and when withdrawn was coated with a thin layer of sterilised vaseline. If catheters were wanted some time after sterilisation, they could be placed separately in glass tubes and sterilised in the same way, each glass tube being corked up with a sterilised rubber plug after withdrawal from the steriliser. He showed a number of ingenious contrivances of a similar nature for sterilising one or more catheters very rapidly, and also a sterile lubricated catheter in a hermetically sealed case which could be carried about ready for use.

Mr. Raymond Johnson had found the method of boiling water and oil in a test-tube for sterilisation and lubrication of a catheter efficient, but the boiling oil tended to roughen the catheter.

Mr. Daniel had also used this method, but had much greater success with Mr. Herring's steriliser, which he had used for some time. He had not had an instance of cystitis after this method of catheterisation.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting at the Medical Institution, Liverpool, Friday, October 19th.

Mr. R. Favell (Sheffield), President, in the Chair.

Dr. A. W. Lea (Manchester) showed a specimen consisting of a portion of skin from just below the umbilicus with a fistulous trail extending from it to the ovary. The whole was removed by abdominal section.

Dr. Lloyd Roberts (Manchester) showed a specimen of carcinoma of the clitoris, the third case he had seen within a few months. Also a complete specimen of ruptured ectopic gestation of about three months' growth.

Dr. Walter (Manchester) showed a uterus removed from a single woman, æt. 27, with a sub-peritoneal myoma which occupied the broad ligament. This required special treatment, and was bunched up and sutured in several places to avoid the formation of a hæmatoma. The uterus also contained a small fibroid undergoing cystic degeneration.

Dr. W. Blair Bell (Liverpool) mentioned two cases of fibromyomata which presented interesting complications.

Dr. W. F. Shaw (Manchester) read a paper on

Chorea of Pregnancy

illustrated with 11 cases which had occurred in the practice of St. Mary's Hospital, Manchester, during the last fifteen months. The first two cases were treated on traditional lines, given nourishing diet, arsenic, salicylates, and finally abortion induced, with the very worst results; both mothers died and also both children. The succeeding nine cases were treated on the supposition that their condition was due to a toxæmia; they were kept strictly in bed, their diet consisted solely of milk, and elimination was increased by acting on the bowels, skin, and kidneys with purgatives, diaphoretics, and diuretics. Thyroid extract was given to five patients without any definite result. Under the treatment every mother recovered, and all the children were born alive except one which could not be resuscitated, although the fœtal heart was heard a little time before delivery. Only four patients gave a history of previous chorea, or rheumatism; the remaining seven had histories of shock or worry, though two of these were doubtful. Nine patients were primiparæ, one had one previous pregnancy with chorea; the remaining patient had had two previous pregnancies without any chorea.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 21st, 1906.

Chronic Leucæmia.

Leucæmia is characterised by an enormous and progressive increase in the number of the white corpuscles of the blood, and can be observed under two principal forms: *lymphogene* leucæmia, characterised by the increase of the non-granular mononuclears, and a decrease in the red corpuscles and the polynuclears; *myelogene* leucæmia, with increase of all the granular leucocytes, and especially the myelocytes, and decrease of the red corpuscles. Leucæmia can be either acute or chronic, but the former is rare.

A patient suffering from chronic leucæmia gets gradually weak and thin, while the skin becomes of almost livid pallor. These general signs are frequently to be observed at the very outset of the affection, but in many cases they are preceded by some local but very characteristic signs. Generally the patients complain of a sensation of tension, weight, and even of pain in the left hypochondriac region, or of gastric troubles, such as tedious digestion and tympanism. In some cases abundant gastric hæmorrhage or recurring epistaxis aggravate the already pronounced anæmia. On examination hypertrophy of the spleen is found, with which is associated sooner or later other signs, as tumefaction of certain superficial glands, chiefly the sub-maxillary. Later on new glands are affected, constituting chains, which ultimately fuse into one hard mass. Sometimes these signs are wanting or are little apparent; the pallor and the frequent tendency to hæmorrhage are the principal troubles which guide the medical attendant to seek for more special physical signs. The glands, the spleen, and the liver should be carefully explored. Although the cervical ganglions may not be attacked, those of the axillary, inguinal, iliac, and popliteal regions should be examined—they are frequently found hypertrophied. The increase in volume of the spleen is one of the most habitual signs of leucæmia. At the very outset of the disease the spleen is increased in volume, passing below the false ribs and invading all the left hypochondrium; to the touch it seems smooth and regular. It increases in size progressively, and finally fills up the left iliac fossa, provoking digestive troubles and difficulty in the respiration.

Hypertrophy of the liver is frequent, but not to the same extent as that of the spleen.

Other symptoms may exist, such as anorexia, vomiting, diarrhœa, cutaneous lesions (eczema), priapism from thrombus of the cavernous body, pains in the spine, the sternum, or the long bones, retinitis (one-fourth of the cases) œdema of the extremities, phosphaturia, increase of uric acid. The patient falls into a state of cachexia, fever sets in, and death supervenes from marasmus. The duration of the malady is from one to two years, but the end may be hastened by an attack of hæmorrhage.

Acute Leucæmia.

Parmentier resumes the essential clinical features as follows:—The début is brusque but variable in its symptomatic expression. One patient, perfectly healthy, is suddenly seized with abundant epistaxis, slight rigors, headache and prostration, and enters the hospital with all signs of purpuric infection. Another presents fever, cutaneous hæmorrhage, ulcerative stomatitis, which in a few days determines gangrene of the gums, of the cheeks, and the lower lip. In a third

the affection commences insidiously by great prostration, with dyspnœa soon followed by an eruption of purpura, tumefaction, and bleeding of the gums.

Sometimes acute leucæmia manifests itself by pains in the joints and erythema, easily mistaken for acute rheumatism, or by œdema of the face or a sensation of debility, with pain in the region of the spleen.

The cutaneous hæmorrhage sets in early, the skin is covered with purpuric spots, the gums and the mucous membrane of the mouth are swollen and bleed easily, and finally become covered with ulcers.

The patients are profoundly anæmic, as is witnessed by the general debility, the pallor of the skin, vertigo, and palpitations. The tumefaction of the liver, the spleen, the glands, are much less pronounced than in the chronic form, or may be entirely absent. The uric acid in the urine is enormously increased, while albuminuria is constant. The malady may run its course in three or four days, but it never exceeds eight or ten months, and is always fatal.

CYSTALGIA.

The following will be found of great service in treatment :—

Bromide of camphor, 2 grs.
Ext. of valerian, q.s.
Per one pill. Four daily.

Tincture of thurga accidentalis, 10 grams.
Ten drops three times a day.

Chloroform, 2 dr.
Ether, 3 dr.
Spirits of camphor, iv grs.
To rub on the lumbar region twice a day.

GERMANY.

Berlin, Oct. 21st, 1906

AT the Naturforscherversamnilung Oberstabsarzt, Bieck spoke on the supervision of the soldier. Perhaps nothing that has yet occurred has shown the value of such supervision as the late Russo-Japanese War, in which intelligent care of the soldier practically added many thousands of seasoned men to the ranks of one of the contending armies. Dr. Bieck recognises that in European armies also more attention must be paid to the health of the fighting man. Military surgeons, he says, should show activity in barracks, on parade grounds, on the march, supervising the healthy man, and should use their hygienic knowledge for the maintenance of the soldier's health. He, and not the officer, should arrange the bill of fare, and should care for the needful dietetic changes, and say what is and what is not suitable. Wheat bread in its turn is urgently needful. In the canteen the soldier should be able to procure what fills up the deficiencies of the ordinary diet. He should be able to buy fat, lard, bacon, good country butter, or at least margarine that is above suspicion, albumen in the form of herrings or thin cheese, cakes, and fruit or vegetables. The beer should be nourishing and cheap, and spirits should be forbidden altogether. The surgeon must visit the canteen often and unexpectedly. The greatest cleanliness must be observed in the living and sleeping rooms and in the latrines. The "Kommissgeruch" must disappear. Frequent bathing—a daily bath or at least a daily douche. In summer, in connection with bathing in the open air, there should be sun baths, gymnastic exercises, the soldier being unclothed, or at most having only bathing drawers on. On the parade ground the surgeon should observe which men the exercise tells on, and which quickly get out of breath. He must further note the weak ones, and those with inherited or other tendencies to disease. He must not rely on the weaklings being brought before him. Early dismissal of men who are not able to fulfil the military requirements often prevents life-long invalidism. On every long march a surgeon should accompany the troops as the counsellor of the officer in command. He must give advice as to suitable clothing, and on the choice of material his word should be decisive. Sunstroke will not cease until the present clothing is changed. In summer, instead of woollen, it should be linen, drill, or khaki. In summer, also, the foot-covering should be lighter than in winter; half-wool or cotton socks; thin shoes or sandals in place of heavy boots. Sweaty feet and blisters might be avoided in this way. In the surgeon the soldier should see the benevolent adviser rather than the superior officer. The soldier cannot choose his doctor, and for this reason the doctor ought to strive to gain the men's confidence and trust.

SCOPOMORPHINE.

Under this name a preparation has been brought out by Riedel, Berlin, intended to play a part in producing anæsthesia. It is a compound of hydrobromide of scopolamine and hydrochlorate of morphia. It is claimed that hydrobromide of scopolamine has certain definite properties and produces a definite effect without any disagreeable or unwished-for by-effect. The intention is to employ it for producing total anæsthesia (scopolamine-morphia narcosis of Korff). The patient is to be prepared beforehand. The bowels must be opened and the teeth and buccal cavity, if possible, kept in order 24 hours before employment. During this period easily-digested liquid food should be given, and an hour before the anæsthetic a quarter of a litre (8 ozs.) of milk tea, milk coffee, or strong broth. (It should be stated that the preparation is sold in sterilised ampullæ.) One-third of an ampulla should be injected two and a half to three hours before the operation, a second third one and a half hours before, and the last about three-quarters of an hour before. The anæsthesia is completed by ether spray or minute quantities of ether or chloroform. After the first painful skin incision but little of these latter anæsthetics will be required—perhaps none at all. From the time of the first injection the room should be kept dark and absolutely quiet.

After the operation the patient should be left at rest to enjoy the full benefit of the anæsthetic. When he begins to waken he may have some Fachingen or Vichy Celestine water in teaspoonful doses, and after about six hours a cup of broth or milk tea.

For what is called half-anæsthesia for obstetric cases, etc., half the above-named doses are given.

It is also used as an analgesic and sedative for the calming down of excitement and the relief of pain, as in inoperable carcinoma and tabes, for instance. Here one-sixth, one-quarter, or a half of an ampulla may be given once or more times daily. The general employment of scopolamine has hitherto failed, as is known, owing to the impossibility of manufacturing the alkaloid in a sufficiently pure and stable form. Now success has been attained in this direction, it is expected to come into more general use.

THE HANDLING OF FOODS.

Dr. Cohn, of Charlottenburg, in the *Med. Reform*, calls the attention of the police to the unnecessary and uncleanly custom of touching nearly all sorts of foods with the hands of the server at the time of selling. In selling sweets, for instance, the hands of the man, woman, or girl, whether clean or unclean, are thrust into the receptacle containing them. A handful is taken out and put on the scales. If too many, the surplus is put back into the receptacle, to be handled at least once more before they leave the premises. Sweets, one remembers, go directly, without cooking or other preparation, into the mouth, with all their imperfections on them, whatever they may be. But, as the *Deutsch. Med. Zeit.* points out, there are shops *and* shops, and the would-be buyer need not buy if he sees any mis-handling of the food-stuff he was intending to purchase. Education will mend these and many other matters in time, and the public itself may hasten the process almost as fast as it likes if it will only take trouble to do so.

AUSTRIA.

Vienna, Oct. 21st, 1906.

DISEASE IN THE LARGE INTESTINE.

SVEHLA drew attention, at the Prague meeting, to several diseases in the mucous membrane of the large intestine that simulated other diseases, or, rather, the symptoms lead the clinician astray in his diagnosis. A simple hyperæmia was often so severe in its

symptoms as to lead to the belief in a rupture; while others give rise to such localised pain in the extremities as arouses the suspicion of coxitis. Irritation of the large intestines will produce spermatorrhœa, and lead to the erroneous diagnosis of gonorrhœa.

His method of treating such intestinal troubles was to give a patient a sitz bath three times a day, or after every motion if the bowels move often, and treat the large intestine with 2 per cent. cocaine ointment of vaseline. The bowel should be brought into a loose condition as soon as possible, and cocaine suppositories used, containing 0.01 of a gramme = .15 of a grain each. Five to seven days is the usual duration of such treatment in very severe cases.

Xanthoma Tuberosum.

Brandweiner showed a boy, 5 years old, with large tubercles in the cutaneous surface, which were examined histologically and found to contain all the characteristics of xanthoma tuberosum, which confirmed the clinical diagnosis.

The peculiarity of this case lay in the absence of diabetes and icterus, both or either of which are usually associated with the disease. The boy was brought to the clinic suffering from diphtheria, from which he recovered, leaving the xanthoma.

Umbilical Hernia.

Escherich exhibited a six weeks' child with a hernia that had existed from the fourth day after birth. When admitted, the swelling was about the size of a hen's egg, with a very wide base, unfitting it for surgical operation. A dry powder was used over the ulcerating navel cord, which gave off an offensive odour. The temperature continued high for some time, but ultimately fell, followed by healthy granulation, which he hopes will finally heal without further interference.

Epidemic Cerebro-Spinal Meningitis.

Semerad reported the case of a 13-year-old girl who appeared to suffer from cerebro-spinal meningitis, but the attack was so slight that a bacteriological examination of the cerebro-spinal fluid was necessary to confirm the diagnosis by the presence of the meningococci. After eight days she began to recover for a short period, but the fever began to intermit, with severe pain in the head and occasional jerking, which extended down the neck, with slight paresis down the left side of the face, associated with vomiting. The fluid from the cerebro-spinal membranes was again examined, and found normal. After this she became rapidly worse, becoming unconscious, with paralysis of the right side of the face, right extremities, with involuntary emissions of fæces and urine, and high fever. Shortly after this, all these symptoms disappeared, and the patient recovered, leaving aphasia and deafness as the sequelæ, which we cannot clearly explain. The deafness seems to be improving, but the aphasia remains stationary.

Rhinoscleroma.

Mesicek and Guttmann demonstrated a case of this disease. Frankenburger raised a discussion on the locality—the north-east of Bohemia—where this patient had come from, which was a centre of the disease. He advocated isolation and medical control of the neighbourhood. Finally, a commission was formed by the Society to undertake the examination and report on the subject.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Royal Infirmary, Edinburgh.—At their last meeting the managers made the following appointments to the staff of the institution:—Dr. Harry Rainy, to be assistant physician, vice Dr. Philip, promoted to be full physician; Dr. John S. Fraser, to be assistant surgeon in the Ear and Throat Department; and Dr. R. C. Low to be assistant physician for diseases of the skin.

The Professor of Physiology, University of Glasgow.—Dr. Noel Paton was entertained at dinner by a numerous company of his Edinburgh friends on the 16th inst., prior to his taking up his duties in Glasgow. The function took place in the hall of the Royal College of Physicians, and was presided over by Sir John Batty Tuke, M.P., the croupiers being Dr. John Playfair and Mr. C. W. Macgillivray, the presidents of the two Royal colleges. Dr. G. A. Gilson proposed Dr. Paton's health in felicitous terms, and after replying Professor Noel Paton proposed "The Edinburgh School," to which Professor Cunningham replied. The toast of "The Glasgow School" was given by Professor Schaefer, and responded to by Professor Stockman. Professor Paton took up his new duties on the 19th, when he was formally introduced by Professor Stockman, Dean of the medical faculty, and delivered his inaugural lecture. After paying a tribute to his two predecessors, Professors Andrew Buchanan and McKendrick, he defined the purpose of the medical profession as a great organisation to prevent, rather than cure, disease. The reason why they were not more successful was want of knowledge. Magnificent as their victories had been in fighting cholera, diphtheria, and tuberculosis, the territory compassed was small in comparison with that still unsubdued. Cancer remained, but when they obtained, as they must, knowledge of its nature, it would become as preventible as cholera. The public, however, must take a share in their quest, and give it moral and material support. The medical profession knew, and they must see that the public also knew, that for the advancement of medicine and surgery experiments on the lower animals were required.

Opening of the Winter Session.—The winter session opened in Edinburgh on the 16th. A new departure in the systematic teaching of medicine has been made in the extra-mural school. Three of the most popular teachers, instead of each conducting a separate course of lectures, have combined their forces, and will now give a conjoined series of a hundred lectures, in which each will deal with the department of medicine over which he has especial mastery. The idea is quite revolutionary, as nothing of the kind has hitherto been attempted. If we are to judge by the numbers of students who are attending the combined class it will be as successful as it is novel, and one may predict that Drs. G. A. Gilson, Bruce, and Philip will have not a few imitators in the other branches of medicine within a very few years.

Opening of the New Physical and Engineering Departments, University of Edinburgh.—These new departments, which have been constructed on the site of the old fever hospital, the buildings of which have been to a great extent utilised in the process, were formally opened on the 16th by Dr. Andrew Carnegie, on whom at the same time the degree of LL.D. was conferred. Mr. Carnegie's address took the form of a plea for science teaching, and a protest against the classical tradition and outworn philosophy and metaphysics. He condemned the retention of Greek as a necessary preliminary to obtaining a degree at Cambridge, and rejoiced that the Chancellor (Mr. A. J. Balfour) had travelled to that university to vote against it. Mr. Carnegie also gently satirised two of his hearers (Mr. Balfour and Mr. Haldane) who, he said, "found recreation from the high affairs of State searching for the foundations which are never found, or for the pathway to reality, proving to the satisfaction of readers that there is about the pathway no reality whatever." Subsequently Mr. Balfour in his turn, in acknowledging the debt which the University owed to Mr. Carnegie and Lord Elgin, poked a little mild fun at Mr. Carnegie, who, he said, began with a broadside which certainly demolished the Chancellor of the University, the Lord Rector, the Professors of Ancient Languages, the Professors of Divinity, and the Professors of Philosophy. But all Scotsmen, he said, had the taint of metaphysics in their blood, and Mr. Carnegie's Scotch blood was too much for him.

Diphtheria Epidemic in Paisley.—On account of the prevalence of diphtheria it has been found necessary to close all the Board schools, and most of the other schools in the town. About 12,000 children are affected by the closing order.

BELFAST.

THE WORKHOUSE SANATORIUM.—At the last meeting of the Board of Guardians, the question of a permanent medical staff for the new sanatorium was discussed, and it was decided to appoint a visiting medical officer and two residents, the senior at £150 per annum, and the junior at a lower rate. The senior will be required to hold office for at least a year. The mode of appointment for the visiting officer has not yet been decided.

PUBLIC HEALTH.—On October 16th, a deputation from the Belfast Citizens' Association waited on the Chief Secretary in Dublin with reference to the general health of the city. The deputation was a large and influential one, comprising men of all shades of political and religious opinions. It was introduced by Sir Charles Brett, and its objects were clearly stated by Professor Byers and Dr. Calwell. They dealt with the high death-rate of the city, the alarming amount of preventable disease, specially typhoid and phthisis, and the questions of milk supply, infantile mortality, and hygiene in elementary schools. Other speakers who followed drew attention to the failure of the authorities to comply with the obligations incurred under the Act of 1889 dealing with the sewage question, with the evils of jerry-built houses on filled-in land, and other causes of bad health in the city.

Mr. Bryce gave a most sympathetic reply, and explained in what way the various points could best be dealt with. A Royal Commission could only be obtained by Act of Parliament if it was to take evidence on oath. The Local Government Board had certain powers not yet exercised in Belfast, which might meet the case. He asked for a written statement of the case put before him by the deputation, and promised it every attention.

On the following day, October 17th, a deputation from the Public Health Committee of the Corporation waited on Mr. Bryce with regard to the necessity for re-introducing into Parliament the Public Health Bill, which was brought in last year and dropped. The sudden zeal of this Committee, following so closely on the deputation from the Citizens' Association, is hardly likely to escape Mr. Bryce's notice, and no doubt will afford him some amusement.

BELFAST CHRISTIAN CIVIC UNION.—Under the auspices of this Society, a two-day Conference was held in Belfast last week, the opening meeting being presided over by her Excellency the Countess of Aberdeen. The Union is a new society, the objects of which are to purify city life and induce men to realise that good citizenship is an essential part of good Christianity. It has already obtained widespread and influential support, and will no doubt prove a power for good in the affairs of the city. The papers read dealt with such subjects as street betting, temperance, the employment of children, charity organisation, infant mortality, and so on. An admirable address was delivered by Professor Byers, who took as his subject "Infantile Mortality, Child Insurance, and Cleanliness." The infantile mortality in England, he said, was about 145 per 1,000—that is, that of every 1,000 children born 145 died in their first year. In Ireland generally it was little over 100, but in Irish towns it was about the same as in England, and in Belfast it was 150 for the past six years.

LETTERS TO THE EDITOR.

"DIRECT REPRESENTATION" ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I had decided to withdraw my name from the list of applicants for the election of three direct representatives on the General Medical Council, and this decision has been mentioned in the *British Medical Journal* for October 6. The advice of professional friends, on whose judgment on this matter I rely more than on my own, has induced me to reconsider the question, and I now beg to offer myself as a representative of the profession on the General Medical Council.

For thirteen years previous to 1888 I was a general practitioner at Hartlepool, and as medical officer to large clubs and friendly societies, and Medical Officer of Health to the Borough and in private practice also, I obtained an extended experience of the requirements of ordinary everyday practice and practitioners.

For the last five years I have been President of the Northumberland Medical Association, now merged with the North of England Branch of the British Medical Association, and known as the Northumberland Committee. Its functions are limited to the advancement of the interests of its members directly, and indirectly of the medical profession in Northumberland. The work that has been done by us here, especially in increasing the fees for contract practice has satisfied me that, if we know what we want and the whole profession co-operates in any reasonable demand, it will not, because it cannot, be refused.

There is one point on which I must offer a strong opinion. It has been urged that only those in practice as general practitioners should be appointed to fill the vacancies on the General Medical Council. It seems difficult to believe that this view can be held by any but a minority of the 20,000 voters on whom the result depends unless the invaluable services rendered by Sir Victor Horsley can be left out of consideration. In this part of the country we derived very great advantage from the help and co-operation of consultants, and I feel strongly that to divide the profession into independent sections can only end in disaster. The co-operation of all is needful if any real and permanent improvement in the conditions of medical practice is to be obtained. I am acquainted with the work that has been done by the General Medical Council of late years, and am fully in sympathy with the efforts that have been made to suppress disreputable forms of practice. Without, however, a new Medical Act passed on the lines adopted by the British Medical Association, I am of opinion that the chief evils from which the profession now undoubtedly suffers cannot be satisfactorily dealt with.

I am, Sir, yours truly,

RUTHERFORD MORISON.

Saville Row, Newcastle-on-Tyne.

MOTOR-CARS AND DUST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of your correspondent, "A London Physician," is more suggestive than perhaps he intended it to prove. It explains to the reflective observer why the medical profession in England exerts so little influence on ordinary public opinion. Why does "A London Physician" look for an authority to "One of our highest-class newspapers"? The question of mofor-cars and dust concerns the student of hygiene; what can the editor of even a distinguished lay paper know of the matter. Instead of quoting the opinion of the journalist in question, "A London Physician" should rather have assumed the right and the duty of questioning the validity of the criticism. In answer to the familiar charge that the motor-omnibus is "noisy," why did he not state that this purely relative defect is being rapidly remedied by improved machinery? In reply to the trivial accusation of objectionable "smell," why did he not remark that it is a mere matter of temporarily defective respiration (*i.e.* carburation)? To remove the reproach of "ugliness" why could he not invoke the tyranny of evolution which forces the motor-car to resemble an antiquated stage-coach? And lastly, why did he not use the opportunity in meeting the incrimination of "dangerous" to deliver an instructive lecture on the growing complexity of our higher reflex nervous action?

How many journalists know that the horse is the host of the bacillus of lockjaw (tetanus)? How many have ever heard bacteriologists ask themselves whether the dust in the street, contaminated from the same source, is not one of the causes of the fatal summer diarrhœa of children? When I was a student at Middlesex Hos-

pital I remember Mr. Walter Lang often remarking in the out-patient department on a windy day: "We will soon have the usual series of cases of inflamed eyes." And his prediction was invariably verified. That was a time when the newspapers deplored the prevalence, owing to the ignorance of the population, of infective ophthalmia in Egypt!

"A London Physician" should read M. Clemenceau's recent speech at Draguignan. It should, in the first place, have a superficial interest for him. For the speaker resembles your correspondent in being a medical man, but differs from him in using a motor-car! And it should have, on a deeper study, an animating influence upon him, for the powerful and fascinating orator would show him what medicine and medical men are doing for a socially aspiring France. M. Clemenceau informed his audience that the new subordinate departments of hygiene and social science are already forming the elements of a ministry in the future. I am afraid that this coming ministry would scarcely seek for inspiration in the view of "A London Physician."

I am, Sir, yours truly,
A. W. Gilchrist, M.D.

Nice, October 20th, 1906.

THE SUPPRESSION OF QUACKERY.

To the Editor of The Medical Press and Circular.

Sir,—In one of your recent leaders deploring the backsliding of *The Times* in publishing quack puffs of the sort formerly denounced by its editors, you remarked that the probable result might be that inferior papers would now "go one worse" than the erstwhile leading journal. Your prophecy has unfortunately turned out to be correct. I send a copy of a country paper in my locality in which appear two puffs of the cruel kind which promise cure of organic disease by medicines. Formerly all puffs in this paper were marked conspicuously "advt."; these puffs are printed in every respect like editorial matter, and will no doubt drive simple readers into the hands of the quacks. If the proprietor of this paper were appealed to he would no doubt reply that not only *The Times* but all the leading newspapers do the same. How could he be expected to take a higher stand than the proprietors of *The Times*, or the noblemen who own great London dailies—*The Telegraph*, *The Daily Mail*, and *The Morning Post*—and who have made their position and their wealth through this property.

I am, Sir, yours truly,
Surrey, Oct. 20th, 1906. S.

OBITUARY.

JAMES FINLAYSON, M.D., LL.D., L.R.C.S.

Death has robbed Glasgow of one of the leading ornaments of its medical school in the person of Dr. James Finlayson. His name and fame have reached far beyond the bounds of the city in which he practised, and are household words South of the Tweed and in the British Colonies. Born in 1840 in Glasgow, and educated at the High School of his native city, Dr. Finlayson began his college career as an arts student at the early age of sixteen. But he soon turned out into the world, and earned his living in business for five years before taking up medical study in 1863. After a distinguished university career, he graduated M.B. with honours in 1867, and at the same time took the L.R.C.S.Edin. After serving as house physician at Manchester, and as assistant to Sir William Gairdner at the Glasgow Royal Infirmary, he was appointed physician to the Western Infirmary in 1875. In 1883 when the Glasgow Sick Children's Hospital was opened, he was elected physician, and in this post he served till 1898, when he was made consulting physician. As a clinical teacher, Dr. Finlayson was widely and deeply appreciated, as his classes abundantly testified, whilst as a consultant he was in great request. His opinion was always worth having, and none who called him in a difficult case ever failed to glean something from his peculiarly sagacious and well-balanced mind. But Dr. Finlayson's fame will not die with him, for he was the author of perhaps more books and papers than any man in the profession. No less than sixty contributions he made to the *Glasgow Medical Journal*, twenty or more to the *British Medical Journal*, and just ten to the New York *Archives of Pediatrics*. His taste for medical literature was evinced by his holding for twenty-five years the post of librarian to the Faculty of Physicians and Surgeons of Glasgow, an institution of which he was particularly fond, and of which he became successively vice-president and president. Finlayson's *Clinical Manual* is known the world over by students. In America, under the title of "Clinical Diagrams," two large editions were speedily exhausted soon after publication. Of his other works a mere list would extend to two columns, but we cannot forbear to mention particularly his erudite contributions to the history of medicine. Dr. Finlayson was performing his usual professional duties on the 8th of this month, when he was taken suddenly ill. His death, which took place on the 10th, came as a great shock and grief to all those associated with him.

FREDERICK HURST CRADDOCK, M.A. Cantab., M.R.C.S. Eng.

We regret to announce the death of Mr. Frederick Hurst Craddock, medical superintendent of the Gloucestershire County Asylum, who was found dead in his bedroom at his residence at Wotton, Gloucester, yesterday. He was fifty-five years of age, and had occupied the post for twenty-four years. For a long period deceased suffered from heart affection. His medical education was carried out at St. Bartholomew's Hospital Medical School, whence he took the diploma of the English College of Surgeons in 1877. His loss will be greatly felt in the county.

Dr. TOM WALKER.

By the recent death of Dr. Tom Walker, announced yesterday, the medical profession in Manchester has lost a man of brilliant parts and promise. At the age of twenty-eight he determined to leave the work of a schoolmaster and to enter upon the study of medicine, having in the meantime taken his B.Sc. at the London University. He entered the Medical School at Owen's College, where he was the first holder of the Professor Tom Jones Memorial Surgical Scholarship, of the value of £100. At the time of his death he had just passed the 37th year of his age.

LIEUT-COL. CALEB WILLS, C.B., L.R.C.S.I. L.R.C.P.I.

Lieut.-Col. Caleb Shera Wills, C.B., died at his residence, Lunecliffe, Lancaster, on Friday night, after a lingering illness, aged seventy-two years. He took part in the Zulu War in 1879, being senior medical officer at the base of operations, and of the line of communications between Durban and the Lower Tugela, and received a medal and C.B. for his services. Deceased qualified in 1861.

FRANK LESLIE PHILLIPS, M.D. Brux., M.R.C.S. Eng.

We regret to notice the death of Dr. Leslie Phillips at the comparatively early age of forty-nine years. For many years deceased devoted himself to dermatology, and had consulting rooms in London and in Birmingham. During the past few years, however, he lived at Leamington, and practically retired from practice. He was educated principally at Queen's College, Birmingham, and at the London Hospital. He took the diploma of the English College of Surgeons in 1882, and the M.D. of Brussels in 1883. He was closely associated with the late Mr. Lawson Tait in the Medical Defence Union, but later seceded from that body and was one of the founders of another similar association. For many years he held the post of surgeon to the Birmingham Hospital for Skin and Urinary Diseases.

SPECIAL ARTICLE.

REPORT OF THE IRISH PRISONS BOARD.

THE Report of the General Prisons Board, Ireland, for the year 1905 (*a*) shows that Ireland remains in a fairly satisfactory condition as regards crime. The daily average number of prisoners, 2,601, in 1905, was almost identical with that in the previous year, 2,570. The proportion of the daily average number of prisoners to the total population has remained practically stationary for several years; but it is to be noticed that the number of convicts has shown during the past ten years a very remarkable decrease. In 1896 the average daily number of convicts in Irish prisons was 395; last year it was 238, showing a diminution in that period of 39 per cent.

One hundred and ninety-six juveniles (*i.e.*, under 16 years of age) were committed during the year. Of these, 31 were either discharged or remained untried, and 165 were convicted. Of the latter, 100 were sentenced to short terms of imprisonment; 29 were discharged under the Summary Jurisdiction over Children Act, or under the Probation of First Offenders Act; 30 were sent to reformatories or industrial schools; and 5 were bound over to keep the peace. It is satisfactory that the number of juveniles committed shows a marked decrease during the past ten years, no less than 343 having been committed in 1897. It is remarkable that no less than 12 children under 12 years of age were committed to prison during the year. It is significant that, of these, 4 committals came from one Bench. Regarding the imprisonment of children of tender age, the Prisons Board make the following remarks:—

"We cannot too strongly express our regret that children of from 9 to 11 years of age are still sent to prison by some magistrates, as the above table shows, for such offences as throwing stones into a harbour or in the street, loitering at a harbour or near goods, or trespassing in pursuit of game. Although the common objection to sending children to gaol—viz., the allegation that they 'herd with common criminals'—is absolutely untrue, the practice is deplorable on other grounds. They become for life branded with the prison taint, and being well and kindly treated, lose the salutary dread of prison of which they acquire no experience in its severer disciplinary aspect. All juvenile prisoners are located in a part of the prison entirely by themselves, and have no intercourse whatever with adult prisoners. Those under sentence of a month's imprisonment and upwards are sent to Mountjoy Prison, Dublin, for special reformatory treatment. A considerable amount of time is devoted to school, gardening, and physical drill. They are also taught some useful industry, at which they work in their cells with doors open under the supervision of specially selected officers."

With regard to the health of prisoners, the Report states:—

"The health of the prisoners has been good. There was very little zymotic disease except influenza; there was no case of either typhus or typhoid fever.

"Among local prisoners there were, excluding an execution, 5 deaths. Two were the result of cardiac syncope in constitutions debilitated by drink, 1 was caused by valvular heart disease, 1 by delirium tremens, and 1 from sudden failure of the heart's action. There were 2 deaths in the convict prisons, 1 from paralysis, and 1 from angina pectoris. From local prisons 31 were released on medical grounds before the expiration of their sentences, and one from the convict prisons. Of these, 11 were women who were near their confinement.

"Sixty-four insane prisoners were transferred from local prisons to lunatic asylums. Out of this number 52 were insane on reception, 5 had been ordered to be detained during the pleasure of the Lord Lieutenant as having been insane at the time of committing the offence, or being incapable of pleading, and of the remaining 7, 1 was weak-minded, 1 was an epileptic, and 1 had been an asylum inmate. Two insane convicts were transferred to Dundrum Criminal Lunatic Asylum; 1 of them had always been weak-minded."

It is satisfactory to learn that during the past 13 years corporal punishment has only been administered twice. It is never now inflicted except for mutiny, incitement to mutiny, or gross personal violence to an officer or servant of the prison.

The Board express regret that at only one prison has advantage been taken by Visiting Committees of the power given to them under the new rules introduced in 1902 to organise lectures for prisoners—*i.e.*, at Dundalk Prison, where the series of lectures delivered in the year 1904-5 was followed by another lecture, the subject of which was "Temperance and Hygiene," on October 8th, 1905.

In the prisons generally there is an increase in industrial employments for the prisoners.

In Ireland there is one State Reformatory for Inebriates, situated at Ennis, and during the year 10 persons were committed to it. As five years have now elapsed since habitual drunkards began to be discharged from Ennis, the Board is able to afford some information with regard to the effects of the treatment. During the five years, 63 persons have been discharged; of these, 5 are dead, 3 in lunatic asylums, 4 re-committed, 21 relapsed, 27 doing well, and 3 whose after-history is unknown. This record is certainly not unsatisfactory, but nevertheless the Board hope for better results if the committals were earlier and the sentences longer.

The Report as a whole furnishes much interesting reading, and its arrangement is more simple than that of most Government publications.

(*a*) "Seventy-eighth Report of the General Prisons Board, Ireland." With an Appendix. Dublin: Printed for His Majesty's Stationery Office by Alexander Thorn and Co. 1906. Price, 8½d.

LITERARY NOTES.

THE October number of the *Westminster Review* contains a statistical and well-reasoned article on the "Progress of Insanity in Our Own Time," by Mr. W. J. Corbet, in which he shows the increase of insane in this country in a decade to have reached the terrible proportions of 25,000.

***

THERE is an amusing satire in a recent issue of the *World*, by Oakley Williams, introducing its readers, in dialogue form, to two recognised types of medical men, under the heading "Bedside Manners." Lady Ethel Chloride is suffering, or imagines she is suffering, from indigestion and a cold in the head; she wants an excuse for getting her husband to take her to Egypt to spend the winter. Dr. Jones, a young man of distinguished academic career, who has recently started in private practice, enters, and after the customary questioning, tells the patient honestly, although in scarcely polite professional language, that there is nothing seriously the matter with her—nothing, in fact, that cannot be readily cured with a little walking exercise and a dose of simple medicine. Exit Dr. Jones, the patient being soon after visited by Dr. Lequaque Smith, of irreproachable get-up and suave to breaking point. He has been strongly recommended by a lady friend, and tells her her case is one of great scientific interest, frightens her by talking of the antrum of Highmore, the Eustachian tube, and the vermiform appendix, and, finding his cue, suggests she should spend the winter in Cairo after his treatment—limited to two visits per diem for three weeks—and retires, conscious of having secured a wealthy patient, and she delighted at the discovery of a man who exactly understands her constitution.

***

WE have received from the *News of the World* office a book of over 200 pages, entitled "Medicine for the Million." It is written by a family physician, and contains a large amount of useful information arranged under alphabetical headings. Many terms are used,

however, which are too technical for the lay reader, and actual prescriptions should have been entirely omitted from a book such as this. The price is 1s. net.

***

Among British health resorts, Bath, Buxton, Harrogate, and Matlock, stand pre-eminent. Of their claims to the consideration of the medical profession when it becomes, as it necessarily does daily, a question of the suitability of one or the other for their patients' particular needs, it is not our purpose here to speak. Before us lies a gorgeously-illustrated guide-book, entitled "Harrogate for Health and Pleasure," written and compiled by Hy. J. Buckland, and published by the corporation of Harrogate. If anything in the nature of beautiful pictures could attract, nothing better than this book would be necessary for the purpose. But this health resort has more than its picturesque surroundings to recommend it; its bathing establishment is probably the most perfect in Great Britain, its hotel accommodation unique, and the comfort and amusement of its visitors are as well catered for as at the most favoured resort on the Continent. All this is described and illustrated in the book before us, which we understand is sent free to members of the profession on application.

THE NEW PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

We reproduce above a portrait of the newly-elected President of the Royal College of Physicians of Ireland. Dr. J. M. Redmond is well-known and is most popular in Irish medical circles. He obtained the Licence of his College in 1878, the Membership in 1881, the Fellowship in 1884, and in 1901 and 1902 he served as Vice-President. He holds the posts of Visiting Physician to the Mater Misericordiæ Hospital, and of Consulting Physician to the Coombe Lying-in Hospital and St. Michael's Hospital, Kingstown. He has made numerous contributions to medical literature both in these columns and in those of our contemporaries.

REVIEWS OF BOOKS.

THE TREATMENT OF GONORRHOEA. (*a*)

The terseness of the author's style makes this book pleasant reading, besides the evidence acquired during its perusal that Mr. Leedham-Greene knows what he is talking about, and that, whilst shunning the realms of theory so often invaded by writers on venereal diseases, he is eminently practical. The first two chapters are devoted to "Some Important Details Concerning the Anatomy of the Urethra and Bladder," and here the author rather shatters the theory of Professor Finger, that the bladder when distended becomes pear-shaped owing to the formation of a "bladder neck" through the yielding of the internal prostatic sphincter. Mr. Leedham-Greene shows by his own experiments that the distended organ is oval, the outline of the urethra in the radiograph being sharply cut off from the bladder with a suggestion of a "bladder neck." He lays also great stress on the separation of the urethra into anterior and posterior by the compressor urethræ. After describing acute anterior and acute posterior urethritis and devoting two interesting chapters to the bacteriology of, and the morbid changes in, the urethral secretion, he enters upon the treatment of (*a*) anterior urethritis, and (*b*) posterior urethritis, pinning his faith to the proper use of injections; the ideal remedy being (1) one that is able rapidly to destroy or remove the virus, the gonococcus; (2) one that does this without injuring the mucous membrane; (3) one that allays the existing inflammation. With reference to chronic urethritis, Mr. Leedham-Greene is of opinion that the frequency with which the prostate is involved is greatly underestimated. The chapters on chronic urethritis and its treatment are very interesting with regard to the pathology, diagnosis, &c.; unfortunately, however, bearing in mind the title of the book, we were disappointed in finding nothing new in the *treatment* of this most rebellious affection, most reliance being placed on Diday's and Janet's methods when only the mucous membrane is affected, and rational and systematic dilatation with bougies or dilators in cases where the inflammation has penetrated deeply into the tissues. We were all the more disappointed as, after having read the author's preface, we were prepared to be startled by some fresh and boldly thought out methods of treatment (made in Germany) to guide English surgeons in their struggle with urethral discharges. Part II. is devoted to the Complications of Gonorrhœa, with a chapter on Gonorrhœal Metastases. The last chapter is excellent, and deals with a very difficult subject, "The Proof of the Cure of Gonorrhœa." Among other dicta in this part of the book the following words should be treasured by all surgeons:—"In treating gonorrhœa, as, in fact, all diseases, the patient must be considered as well as the disorder. We must be careful lest in our anxiety to eradicate the last vestige of inflammation we unduly prolong the treatment, and by centering the patient's thoughts too much on his trouble, we induce serious neurasthenia and hypochondriasis.

The formal opening of the Brussels School of Tropical Medicine took place last week. The school has been founded by King Leopold, and will work in conjunction with the similar establishments of London and Liverpool.

The medical officer for Bermondsey reported to the last weekly meeting of the Council that scarlet fever was excessively prevalent in the borough. The cases were scattered fairly evenly over the whole district, and there was no common cause discoverable, such as milk, school infection, &c. The disease was of a very mild type, so much so that many children were going about with the rash fully developed.

(*a*) "The Treatment of Gonorrhœa in the Male." By Charles Leedham-Greene, M.B., F.R.C.S. Pp. xii., 151, with 36 illustrations. London: Bailliere, Tindall and Cox. Price 5s. net.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of Edinburgh.

AT the Annual Meeting, held on the 17th inst., the following office-bearers were elected for the ensuing year:—

President.—Charles Watson MacGillivray, M.D.

Vice-President.—Sir Patrick Heron Watson, M.D., LL.D.

Secretary and Treasurer.—Robert M'Kenzie Johnston, M.D.

Librarian.—Henry Alexis Thomson, M.D.

President's Council.—Joseph Bell, James Dunsmure, Joseph M. Cotterill, Francis M. Caird, George A. Berry, James W. B. Hodsdon. *Ex-Officio*, The Vice-President, the Secretary and Treasurer, the Representatives on the General Medical Council.

Representatives on the General Medical Council.—James William Beeman Hodsdon, M.D.

Examiners.—John Smith, Joseph Bell, Alexander G. Miller, George Hunter, James Dunsmure, Charles E. Underhill, Sir John Halliday Croom, James Ritchie, William Craig, Charles W. MacGillivray, Joseph M. Cotterill, James Hunter, Charles W. Cathcart, Francis M. Caird, George A. Berry, James W. B. Hodsdon, James Maxwell Ross, Robert M'Kenzie Johnston, Robert H. Blaikie, Robert A. Lundie, Russell E. Wood, George Mackay, Junr., David Wallace, Henry Alexis Thomson, Kenneth M. Douglas, Harold J. Stiles, William George Sym, Henry Harvey Littlejohn, Alexander Miles, Arthur Logan Turner, William Guy, James Musgrove, John W. Dowden, Frederick M. Graham, Archibald A. Scot Skirving, James Veitch Paterson, Theodore Shennan, David Waterston, Nathaniel T. Brewis, James Haig Ferguson, R. Stewart MacDougall, Thomas W. Drinkwater, George H. Gemmell, James Kerr, Cargill G. Knott, Duncan MacDonald.

Public Health Examiners.—James O. Affleck, William Craig, James Maxwell Ross, Henry Harvey Littlejohn, Alexander Buchan, George H. Gemmell, J. Falconer King, Cargill G. Knott.

Dental Examiners.—John Smith, Joseph Bell, William Craig, Robert A. Lundie, William Guy, Archibald A. Scot Skirving, George W. Watson, Frederick J. Turnbull.

Assessors to Examiners.—Sir Henry D. Littlejohn, Sir Patrick Heron Watson, John Smith, John Chiene.

Conservator of Museum.—Henry Wade, M.B.

Clerk.—James Robertson, Solicitor.

Auditor of Accounts.—George H. Carphin, C.A.

Officer.—Clarendon Hyde Creswell.

Assistant to Conservator.—George Reid.

Dr. Jowett's New Appointment.

Dr. H. A. D. Jowett, who has just been appointed Manager of Works of Burroughs Wellcome and Co., acted as chief research chemist under Dr. F. B. Power in the Wellcome Chemical Research Laboratories, and during his ten years' connection with these laboratories he conducted a number of important investigations, notably on the chemistry of the jaborandi alkaloids, the constituents of cascara, etc. Dr. Jowett has distinguished himself at every step of his career. A Bell Scholar in 1891, he passed the Minor and Major Examinations of the Pharmaceutical Society, and secured the Pereira Medal and Redwood Scholarship in 1892. The following year he graduated as B.Sc. London. Between 1894 and 1896 he acted as Assistant Lecturer in Chemistry to the Pharmaceutical Society and Demonstrator in its Research Laboratories, and in 1896 took his degree of Doctor of Science at the London University. His exceptionally brilliant scientific work is well known through papers read before the learned societies, and his contributions to scientific journals. His researches in regard to the active principles of aconitine and jaborandi are classical, and he has contributed largely to our knowledge of effective methods of drug standardisation. During the present year he has been elected a Member of Council of the Chemical Society.

Royal Commission on Trinity College and the University of Dublin.

This Commission has been sitting daily in the Board Room of Trinity College. The sittings are private. During the past week the witnesses called before it have principally consisted of the Provost, Fellows, and Professors of the University. Medical witnesses were called for the first time on Saturday, when Professors A. C. O'Sulivan, M.D., A. F. Dixon, M.B., and W. H. Thompson, M.D., were examined. The Royal Commission have intimated their willingness to receive from persons who have not already submitted their views on the matters in question any objections or criticism which they may desire to submit for the consideration of the Commission, in regard to the schemes, suggesting changes in the constitution and government of the College and the University, which are contained in the appendix to their first report. It is necessary that such statements of objections or criticisms should be brief, and that they should reach the Secretary of the Commission, 16, Ely Place, Dublin, not later than November 1st.

Convocation of the Royal University of Ireland.

The following have been elected members of the Annual Committee for the coming year:—Walter E. Adeney, D.Sc.; S. Lombard Browne, M.A., K.C.; John J. Charles, M.A., M.D., M.Ch., D.Sc.; Denis J. Coffey, M.A., M.B., B.Ch., B.A.O.; John Donaldson, M.A.; Daniel S. Doyle, LL.B.; Francis T. Heuston, M.D., M.Ch.; Christopher Joynt, M.D., Surgeon-General; John C. M'Walter, M.A.; Edward J. M'Weeney, M.A., M.D., M.Ch., M.A.O.; Edward Magennis, M.D.; James C. Meredith, M.A.; Joseph F. O'Carroll, M.D., M.Ch.; John Park, M.A., D.Lit.; Joseph P. Pye, M.D., M.Ch., D.Sc.; Alfred J. Smith, M.B., M.Ch., M.A.O.; Sir Thornley Stoker, M.D., M.Ch.; Andrew Todd, M.A., LL.D.

PASS LIST.

Royal College of Surgeons in Ireland.

The winter session commenced on Monday, October 15th, when the following prizes of the previous session were distributed by Mr. H. R. Swanzy, President of the college.

Barker Anatomical Prize.—£31 10s., P. G. M. Elvery.

Carmichael Scholarship.—£15, C. Greer.

Gold and Silver Medals in Operative Surgery.—Gold, D. Adams. Silver: R. M. Bronté.

Stoney Memorial Gold Medal in Anatomy.—G. S. Levis.

Descriptive Anatomy.—Junior—W. A. Swan, First Prize (£2) and Medal; A. A. Pelissier, Second Prize (£1) and Certificate. Senior—G. C. Sneyd, First Prize (£2) and Medal; I. Scher, Second Prize (£1) and Certificate.

Practical Anatomy.—First Year—H. D. Gasteen, First Prize (£2) and Medal; H. G. P. Armitage, Second Prize (£1) and Certificate. Second Year—H. J. Hedley, First Prize (£2) and Medal; Miss I. M. Clarke, Second Prize (£1) and Certificate.

Practice of Medicine.—H. W. White, First Prize (£2) and Medal; D. Adams, Second Prize (£1) and Certificate.

Surgery.—H. W. White, First Prize (£2) and Medal; T. Sheehy, Second Prize (£1) and Certificate.

Midwifery.—H. C. Carden, First Prize (£2) and

Medal; W. E. M. Hitchins and T. Sheehy (equal), Second Prize (£1) and Certificate.

Physiology.—H. J. Hedley, First Prize (£2) and Medal; J. Menton, Second Prize (£1) and Certificate.

Chemistry.—J. J. Lyons, First Prize (£2) and Medal; R. White, Second Prize (£1) and Certificate.

Pathology.—H. F. Kay, First Prize (£2) and Medal; G. S. Levis, Second Prize (£1) and Certificate.

Physics.—R. White, First Prize (£2) and Medal; R. H. Weir, Second Prize (£1) and Certificate.

Practical Histology.—R. Adams, First Prize (£2) and Medal; O. W. J. Wynne, Second Prize (£1) and Certificate.

Practical Chemistry.—J. J. Lyons and P. I. Wigoder (equal), First Prize (£2) and Medal.

Public Health and Forensic Medicine.—T. C. Boyd and C. T. Cullimore (equal), First Prize (£2) and Medal.

Materia Medica.—J. J. Lyons, First Prize (£2) and Medal; H. W. White, Second Prize (£1) and Certificate.

Biology.—H. D. Gasteen, First Prize (£2) and Medal; J. S. Pegum, Second Prize (£1) and Certificate.

The Royal University of Ireland.

The following candidates have passed the undermentioned examinations:—

The M.D. Degree Examination.—Michael Cagney, M.B., B.Ch., B.A.O.; Charles G. Lowry, M.B., B.Ch., B.A.O.; Isabella G. A. Ovenden, B.A., M.B., B.Ch., B.A.O.; Frederick W. Stewart, B.A., M.B., B.Ch., B.A.O.; John J. Wallace, M.B., B.Ch., B.A.O.

The M.Ch. Degree Examination.—Samuel T. Irwin, B.A., M.B., B.Ch., B.A.O.

The M.B., B.Ch., B.A.O. Degrees Examination.—*Upper Pass.*—Francis X. J. Callaghan; John L. Dunlop, B.A.; James R. Hackett, Robert F. Kennedy, Patrick T. McArdle, Robert M'Crea, A.M.L., Charles B. Pearson, Percy B. Ridge, Maria Rowan, Thomas Tobin, James Warnock, M.A.

Pass.—Charles D. Bell, Samuel Bradbury, Harry L. Bristow, Holden Carson, John Dowling, John Dunlop, Patrick J. Dwyer, Edward Fitzgerald, James J. A. Gannon, James Gaston, Mary E. Jeremy, B.A., Charles G. Knight, Samuel W. Kyle, Morgan Lane, Samuel McCormac, William T. McCutcheon, Daniel McGrath, Jeannie R. Murray, Joseph A. O'Halloran, B.A., Maurice A. Power, William B. Purdon, Charles H. G. Ross, Maurice P. Scanlon, James M. Warnock, Ernest F. Watson, Thomas West.

The following candidates may present themselves for the further examination for Honours in the Groups set after their names:—Francis X. J. Callaghan, Medicine; John L. Dunlop, Medicine, Surgery; Robert F. Kennedy, Surgery; Patrick T. McArdle, Surgery; Robert McCrea, A.M.L., Surgery; Charles B. Pearson, Medicine, Surgery, Midwifery; Maria Rowan, Medicine; James Warnock, M.A., Medicine, Surgery, Midwifery.

Diploma in Mental Diseases. — Frederick W. Stewart, BA., M.B., B.Ch., B.A.O., Queen's College, Belfast.

Royal Academy of Medicine.

The annual general meeting of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians of Ireland on October 12th. Dr. J. Magee Finny was elected President, for three years, in place of Sir Thornley Stoker.

The following officers were elected for the ensuing year:—

General Secretary—James Craig, M.D., Secretary for Foreign Correspondence, Sir J. W. Moore, M.D. Medical Section—President, the President R.C.P.; J. B. Coleman, W. R. Dawson, H. C. Drury, T. P. C. Kirkpatrick, A. R. Parsons, G. Peacocke, F. C. Purser, W. Langford Symes, W. J. Thompson, W. A. Winter. Surgical Section—President, the President R.C.S.; C. A. Ball, Alex. Blayney, Sir A. Chance, T. E. Gordon, W. S. Haughton, G. J. Johnston, J. Lentaigne, R. C. B. Maunsell, E. H. Taylor, W. Taylor.' Obstetrical Section—President, R. D. Purefoy; Paul Carton, Gibbon FitzGibbon, R. H. Fleming, A. J. Horne, H. Jellett, F. W. Kidd, Sir A. V. Macan, A. J. Smith, Sir W. J. Smyly, E. H. Tweedy. Pathological Section—President, J. F. O'Carroll; A. H. Benson, J. B. Coleman, H. C. Earl, L. G. Gunn, E. J. M'Weeney, H. C. Mooney, T. G. Moorhead, A. R. Parsons, J. A. Scott, A. H. White. Section of Anatomy and Physiology—President, A. F. Dixon; D. J. Coffey, A. Fraser, H. M. Johnston, E. P. M'Loughlin, J. Alfred Scott, W. H. Thompson. Section of State Medicine—President, F. C. Martley; A. E. Boyd, T. P. C. Kirkpatrick, E. J. M'Weeney, J. A. Matson, Sir John Moore, W. A. Winter.

Royal Colleges of Physicians and of Surgeons.

Conjoint Examinations in Ireland — First Professional Examination.—Cadidates have passed this examination as under-noted:—H. E. Clarke, J. Devine, H. D. Gasteen, J. Gormley, J. J. Glynn, J. D. Hamilton, E. E. Holden, R. H. Hodges, W. V. Johnston, A. P. Kennedy, A. M. A. Lanphier, L. A. Moran, W. H. Murray, H. M'Adee, J. M'Mullan, T. B. Newman, M. A. O'Callaghan, B. O'Donnell, J. H. O'Neill, J. Purcell, A. Wiley.

Second Professional Examination.—W. S. Coffey, F. J. Colgan, J. Donoghue, D. J. Harty, J. Healy, J. T. Heffernan, L. C. Johnston, J. Marmion, J. J. O'Connell, M. C. O'Hara, W. Rahilly, L. C. Rorke, W. F. Russell, I. Schor, R. S. White. Copies of the preliminary regulations for 1907 can be obtained on application.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The following candidates having passed the requisite examinations of the Conjoint Board during October, were admitted Diplomates in Public Health:—Edward M. Nicholl, M.D., Edin.; David M. Mathieson, M.B., Ch.B., Edin.; Laurence W. Pole, M.B., Ch.B., Edin.; William H. Hill, M.D., Kelso; William Darling, M.B., F.R.C.S.E., Edin.; Hugh A. Stewart, M.B., Ch.B., Pitlochry; Murdoch Macdonald, M.D., Shettleston; Katherine J. S. Clark, M.B., Ch.B., Edin.; Edward Valenzia, M.B., Ch.B., Edin.; Henry M. Sauzier, M.B., Ch.B., Edin.; Thomas Scoresby-Jackson, M.B., Ch.B., Walthamstow; Edward P. Calder, M.B., Ch.B., Coldingham; Francis E. Larkins, M.B., Ch.B., Edin.; and Jamshyd D. Munsiff, F.R.C.S.E., Portobello.

The following passed the First Examination in Public Health:—Francis P. Lauder, Cap., R.A.M.C.; Ferniehirst H. Borthwick, M.B., Ch.B., Edin.; Sohrab Hodiwalla, L.R.C.P. & S.E.Edin., and Thomas R. Smith, M.B., Ch.B., Edin.

Royal College of Surgeons of Edinburgh.

The following candidates, having passed the requisite examinations, were at a meeting of the College, held on the 17th inst., admitted ordinary Fellows:—John R. Askew, L.R.C.S.E., Fochabers; William L. Bennett, M.B., Ch.B., Capt. R.A.M.C.; Bertram M. Bone, M.B., C.M., Marske-by-Sea; Devereux Gwynne-Hughes, L.R.C.S.E., Sydney; H. Astley Knight, M.B., L.R.C.S.E., Lieut., I.M.S.; Charles D. Lochrane, M.B., Ch.B., Glasg.; Arthur L. Lynch, M.D., C.M., Ottawa; George B. McKean, M.B., M.R.C.S. Eng.; Belfast; Maxwell MacKelvie, M.B., Ch.B., Capt. I.M.S.; Edward J. Morton, M.B., Ch.B., Edin.; Frederick G. Twigg, M.R.C.S. Eng., Rotheram; and John H. Yearsley, L.R.C.S.E., Edin.

The medal and set of books presented to the College by Colonel William Lorimer Bathgate, in memory of his late father, William McPhune Bathgate, F.R.C.S.E., Lecturer on Materia Medica in the Extra-Academical School, was awarded after the usual competitive written examination in Materia Medica, &c., to John Joseph O'Sullivan, 31, Warrender Park Terrace, Edinburgh.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Endometritis Atrophica Purulenta Fœtida.—Broese (*Zeitsch. für Geb. u. Gyn.*, Bd. LVIII., Hft. 1) records his observations on two women, aged 65 and 67 years, who had passed the menopause by 18 and 21 years respectively, and who had been suffering for many months from a profuse, purulent, and extremely foul discharge. One patient complained, in addition, that she had cramp-like pains every day in the lower part of the abdomen, and in the discharge shreds of friable material were found. There was no hæmorrhage in either case. Since the purulent matter was certainly coming from the uterine cavity, cancer of the body of the uterus was immediately suspected. Microscopical examination of the curettage showed no evidence of cancer in either case. The tissue removed from the first case looked like an abscess membrane. That removed in the second showed an advanced interstitial endometritis with disappearance of the glandular tissue in some places. The packing of the uterus with iodoform gauze after the curetting improved the condition very materially in both cases. The application of chloride of zinc and antiseptic intra-uterine douches were also found useful. G.

Pyelonephritis in Pregnancy.—Ruppaurer (*Münchener med Wochensch*, 1906, Nr. 6) observed ten cases of this complication of pregnancy within two years. Infection may come either through the blood or through the urine. The bacillus coli plays the most important part. The author's experience coincides with that of Opitz, that during pregnancy by far the most frequent path of infection is upwards from the bladder. Pressure on the ureter by the pregnant uterus, and the consequent damming back of the urine is an especial predisposing cause (the compression pyelitis of pregnancy of Sippel). The disease is more frequent on the right side. It generally makes its appearance during the middle months of pregnancy, and its onset is usually sudden, with rather severe symptoms. The clinical picture is that of the so-called urinary sepsis. The quantity of the urine is at first lessened, but later it is often increased, and its condition is fairly characteristic. Tenderness on pressure is usually found in the region of the right kidney, and there may be also pain on pressure over the path of the ureter. The latter may even be felt from the vagina thickened and painful. The condition generally begins to improve immediately after the conclusion of labour. Endocarditis is a dangerous complication. The disease fairly frequently causes premature expulsion of the uterine contents. Treatment consists in rest in bed, by which means the pressure of the uterus on the ureters becomes less, and at the same time urinary antiseptics, copious drinks, and dietetic treatment are of the utmost importance. Surgical treatment may perhaps also be required. G.

The Intestinal Disturbances of Breast-fed Infants.—As a result of the examination of twenty breast-fed infants during the period from the second to the fifth days of their life, Schahort (*Monatssch. für Geb. u. Gyn.*, Bd. 24, Hft. 1) observed green stools in every case without exception. He found that during the same act of defæcation yellow-coloured matter may be followed by green, or the motion at first green may finally become yellow; and again, although in some cases the daily stools consecutively showed the normal colour for a time, they also ultimately became green. In short, the stools of these infants of three to five days' old were without exception those which can be described as dyspeptic. The transition of this condition to one of normal stools occurred in some of the cases at very varied intervals. From bacteriological examination, the author found that the contents of the rectum immediately after birth were always sterile. The time of the first infection was quite independent of nutrition. Bacteria were found in the meconium from 10 to 20 or more hours after birth. With the appearance of the milk stools the bacillus acidophilus and the bacterium coli were regularly discovered, and in 2½ to 4 days after birth, in addition to the latter, diplo- and staphylo-cocci were found in every case. The disturbances of digestion increase at the same rate at these cocci make their appearance, and the earlier they appear the more severe are the clinical symptoms. The number of these cocci varies according to the severity of the symptoms, and of them the staphylococci are associated most strikingly with the intestinal disturbances. The sources of this staphylococcal infection are very varied. It may arise from air infection, or from substances coming into contact with the infant—e.g., vaginal secretion, bath water, lochial secretion, etc. Cohn and Neumann have shown that the breast milk regularly contains staphylococci, most frequently albus, which have made their way from outside into the milk ducts. It is therefore clear that the milk, when there are long intervals between the nursing, and also during the first suckling, must be rich in staphylococci, and particularly the first milk extracted. Escherich has shown that the milk of septic women contains staphylococci. The clinical symptoms vary very much in the different cases, and undoubtedly depend on the power of resistance of the infant, as well as on the number and virulence of the infecting staphylococci. The question whether the intestinal catarrhs which play so important a part in infantile mortality during the first year of life are fresh exacerbations of chronic intestinal disease, which, beginning in the first days of life, takes on acute forms with every new and severe irritation, or whether, on the other hand, these catarrhs remove a good deal of the resisting power of the infantile organism, and thus render it incapable of resisting later bacterial invasion during the first year of its life—the author leaves this question unanswered. He considers that either may be possible. He believes that icterus neonatorum and these intestinal affections of the first days of life are ætiologically connected. G.

Primary Carcinoma of the Ovary.—McIlroy (*Jour. Obst. and Gyn.*, October, 1906). In an exhaustive paper the author draws the following clinical conclusions with regard to primary carcinoma of the ovary. It occurs at or near the menopause, although found in patients of 24, 25, and 29 respectively. It is almost as frequent among nulliparous as among multiparous patients, previous pregnancies having little or no influence on the disease. Pain is not a marked symptom, patients seeking advice for the relief of the abdominal swelling with its concomitant symptoms. and ascitis is present in all cases. It has a marked influence on menstruation, tending to cause cessation of the periods, but previous dysmenorrhœa was not a marked symptom in any of the cases. There is often little or nothing to suggest the diagnosis of malignancy, and the patient may be in good health until a few weeks before seeking advice; whereas in secondary carcinoma of the ovary emaciation and feebleness are rather prominent symptoms. In most cases the growths are bilateral, generally mobile, and sometimes, if of large size, are entirely extra-pelvic in situation. Metastatic growths depend on the degree of advancement of the growth and on the integrity of the capsule, and have been found in the bladder, uterine wall, and behind the prevertebral peritoneum. The mortality of operation is high, and recurrence is probable. F.

Mitral Stenosis and Pregnancy.—French and Hicks (*Jour. Obst. and Gyn.*, September, 1906). There are certain points in regard to valvular heart disease and pregnancy upon which there is general agreement. They are—Mitral Stenosis, is the form most commonly accompanied by heart failure during pregnancy; Aortic lesions without mitral are rare in women; and few cases come under observation where symptoms of heart failure have preceded pregnancy. They are made worse by pregnancy, and repeated pregnancies at short intervals cause greater risk of heart failure than do few pregnancies at longer intervals. On the other hand, there are some points upon which there is not the same agreement, and amongst these one of the most important, perhaps, is the question of whether a young woman with mitral stenosis should marry. Having analysed the obstetric histories of 300 women, over twenty, who had mitral stenosis, the authors conclude—That it is not just to absolutely negative marriage in all women with mitral stenosis, and that the dogmatic "no" of Jellett and Porak is unjustifiable. It is right that the physician should make clear to the contracting couple, or to their near relatives, the risk run. If the woman has survived the age of twenty with good cardiac compensation, the likelihood that pregnancy will accelerate the time of heart failure does not seem to be so great as has been declared in text-books, and whether the woman marry or not, it is likely that she will not reach old age. That comparatively few are sterile; that they are not especially liable to abort. That the majority bear children well. That when heart failure develops in relation to pregnancy, it is very often not with the first pregnancy, but after several pregnancies. That the treatment should be the same as for a non-pregnant patient with mitral stenosis. F.

Urethral Bacteria as a Factor in the Etiology of Cystitis in Women.—Taussig (*Amer. Jour. of Obst.*, October, 1906). In discussing the etiology of cystitis in women, we must distinguish three main channels of infection, one by way of the ureters, a second directly through the bladder wall from the surrounding structures, and the third from below by way of the urethra. Of these three by far the most frequent route of infection is the urethral. In general, we may say the ureter acts merely as a channel to carry infectious germs from the kidneys to the bladder. The ureters themselves are normally free from germs, and are rarely the primary source of the infectious material. Likewise the bladder wall is seldom a primary seat of infection, but is only secondarily penetrated by suppurative processes, such as pyosalpinx, etc., or by the invasion of colon bacilli from the rectum. How does this rule apply to the third channel of infection—the urethra? Taussig made bacteriological examination of the urethral secretion of fifty women free from any disease of the urinary track or acute pelvic inflammation. The results of the examination, with the lessons to be drawn therefrom in the way of prophylaxis, may be summarized as follows:—1. The normal urethra free of disease is sterile in only a small proportion of cases—8 out of 45 cases. 2. In about half of the urethræ examined pathogenic germs are present. 3. Of the pathogenic bacteria found staphylococcus pyogenes albus is the most common; the occurrence of the colon bacillus seems very variable—it is found frequently where patients are confined to bed. In his series it was only isolated three times. 4. That these urethral bacteria are actually carried into the bladder by catheterisation. 5. Irrigation of urethra with boric acid removes a large proportion of the urethral bacteria; but where the number is great does not suffice to re-remove all. 6. Wherever repeated catheterisation becomes necessary, certain precautions to prevent infection of the bladder should be advised. Give urotropin, or an allied product, internally, and where catheterisation is necessary for a considerable time it is certainly advisable to use boric acid irrigation after each catheter is passed. F.

Chorea Gravidorum.—French and Hicks (*Practitioner*, August, 1906). In a series of twenty-nine cases these observers found a previous history of chorea or rheumatism in nineteen cases. Chorea may be absent during the first pregnancy, yet occurs in a later one. It may come on at any time, but is distinctly less likely to occur during the later months. When chorea occurs in successive pregnancies it is likely to begin in the same month each time. The pathology is similar to that of infantile chorea, and occurrence is frequent. As regards prognosis, a rise of temperature above 100 Fahr. would justify a grave prognosis, whereas a normal temperature would justify a good one, as far as immediate results were concerned, regardless of the severity of the choreic movements. The majority of cases do well when treated in exactly the same way as non-pregnant cases. The induction of labour is seldom called for, even when movements are severe, and after pyrexia has set in it is too late. The mortality is about 10 per cent. F.

The Rubber Teat and Deformities of the Jaws.—Pedley (*Brit. Med. Jour.*, October 20th, 1906) contributes a long article on the subject of the deformities which may be caused in the jaws of infants by the prolonged use of the ordinary form of rubber teat, and of the so-called "comforter." The paper is illustrated by a large number of drawings of casts of such jaws which the author has met with in his practice in Burmah. The author considers that the defective shape and resiliency of the artificial teat, the severe muscular efforts demanded of the tongue, and its altered shape in sucking it, the extra muscular pressure of the lips and cheeks, the enormously increased atmospheric pressure upon the cheeks and jaws, are all abnormal influences which must have injurious effects upon the delicate bony tissues of the infantile maxillæ, and interfere with their proper growth and development. The ossifying junctions of the maxillæ, the premaxillæ, and the mandible are subjected to these unnatural influences during a long period when they are most liable to be injured. When these processes are prolonged, as they often are, until the temporary teeth have all been erupted, or even into the third or fourth years, it is not surprising that the alveolus containing the upper incisors, both temporary and permanent, should be pushed forward, for the bulk of the premaxillæ is alveolus. At the same time the upper alveolar arch, instead of broadening, is compressed transversely by the atmospheric pressure upon the cheeks. This, with the pressure of the bulk of the teat against the palate, destroys the symmetry of its concavity by preventing the descent which accompanies natural development. The palatal arch may thus remain abnormally high in the centre, and sometimes becomes V-shaped. The author's conclusions are: When an infant is deprived of its mother's milk and has to be fed by hand,, the substitute should be quite different in shape and consistency to the patterns now in vogue. It seems so difficult to make, even in india-rubber, a good imitation of Nature, that it would be much safer to be satisfied with providing a soft end to the spout of a vessel from which the infant is to be fed, and through which the milk can be gently and slowly poured into its mouth. No harm can result from a baby drinking without sucking. As a substitute for the common rubber teat, he recommends the use of a good-sized soft rubber finger-stall. Such a teat may be used on the spout of a vessel like a feeding-cup, or an ordinary feeding-bottle. A baby three months old can quite easily be taught to drink from a cup, and at this age he recommends that all teats and bottles be thrown aside, and that we should revert to the old-fashioned metal pap-bowl with the long open lip.

Pharmaceutical Society of Ireland.

Pharmaceutical Licence Examination.—The following passed:—John Alexander Donaghy, Charles Agnew, Thomas James White, William Edmond Walshe. Five candidates were rejected.

Registered Druggist Examination.—The following passed:—William Manning, Isabella Unsworth. Six candidates were rejected.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

R. R. R. (Liverpool).—On enquiry we are informed that a play, in which "Syphilis" played an important part, was submitted to certain Paris theatrical managers with a view to its production on the stage. This was refused, but it subsequently appeared at one of the theatres in Brussels. We have not heard of a translation being made for the English stage, for the obvious reason that the Lord Chamberlain would refuse licence, even should any stage manager be found willing to produce it.

ADVOCATE.—We quite agree that it is wrong for novelists to use the actual names of well-known physicians in their stories. But we do not think any steps could be taken to restrain the practice, unless the intention to libel were obvious.

R.A.M.C. (Vol.).—There have been two well-known types of service water cart. The first pattern was found unserviceable, but the second seems both practical and efficient.

ANEURYSM.—The Röntgen Rays cannot be considered of any value in aneurysm of the abdominal aorta, unless a positive result is obtained. A clearly defined shadow of course would be valuable confirmatory evidence.

D. S. T.—The upright position for the administration of anæsthetics in throat operations is quite common; it cannot be considered unorthodox.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 24th.

HUNTERIAN SOCIETY (Metropolitan Hospital, Kingsland Road, N.E.).—4 p.m.: Clinical Afternoon.

POST-GRADUATE COLLEGE (West London Hospital).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. 5 p.m.: Lecture:—Dr. Beddard: Practical Medicine.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Berry: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. G. H. Savage: The Insanities of Visceral Diseases.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. R. Wells:—Medicine. 3.15 p.m. Mr. M. Robson:—Surgery. 4 p.m.: Mr. Cargill:—Ophthalmology. Out-patients Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.)—5 p.m.: Demonstration:—Dr. W. Wingrave: Clinical Pathology.

THURSDAY, OCTOBER 25th.

HARVEIAN SOCIETY OF LONDON (St. Mary's Hospital).—8 p.m.: Cases will be shown by Dr. S. Phillips, Dr. A. P. Luff, Dr. W. Harris, Dr. J. Broadbent, Dr. S. Spicer, and Mr. J. Clarke. 8.45 p.m.: Clinical Meeting.

POST-GRADUATE COLLEGE (West London Hospital).—2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Diseases of the Eye. 5 p.m.: Lecture:—Mr. Baldwin: Practical Surgery.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. C. O. Hawthorne: The Field of Vision in Health and Disease.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. G. Rankin: Medicine. 3.15 p.m.: Sir W. Bennett: Surgery. 4 p.m.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.)—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: The Treatment of Eczema in all its Forms.

FRIDAY, OCTOBER 26th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Clinical Evening for the Exhibition of Clinical Cases, followed by Discussion. Patients in attendance at 8 p.m.

POST-GRADUATE COLLEGE (West London Hospital).—2 p.m.: Medical and Surgical Clinics. Diseases of the Throat, Nose, and Ear. 2.30 p.m.: X-Rays. Operations. Diseases of the Skin. 5 p.m. Lecture:—Mr. Pardoe: On the Diagnosis of Surgical Diseases of the Kidneys and Ureters.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m. Dr. J. Horne: Clinique. (Ear.)

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.:—Dr. R. Radford: Medicine. 3.15 p.m.: Mr. McGavin:—Surgery. Out-patient Demonstrations. 10 a.m.: Surgical and Medical. 12 noon: Skin.

SATURDAY, OCTOBER 27th.

POST-GRADUATE COLLEGE (West London Hospital).—10 a.m. Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. Out-patients Demonstrations. 10 a.m.: Surgical and Medical. 11 a.m.: Eye.

Vacancies.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary £110 per annum. Applications to Henry T. Dudley Ryder, Secretary.

St. Bartholomew's Hospital, Rochester.—House Surgeon. Salary £110 per annum, with board and residence at the hospital. Applications to Frederick F. Smith, Clerk to the Trustees, 42 High Street, Rochester.

St. Bartholomew's Hospital, Rochester.—House Physician. Salary £110 per annum, with board and residence at the Hospital. Applications to Frederick F. Smith, Clerk to the Trustees, 42 High Street, Rochester,

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Clayton Hospital and Wakefield General Dispensary.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Macclesfield Parkside Asylum.—Junior Assistant Medical Officer. Salary £140, with apartments, board (no alcohol), and washing. Applications to the Medical Superintendent.

Aston Union.—Resident Assistant Medical Officer. Salary £140, with furnished apartments, rations, and washing. Applications to John North, Clerk to the Guardians, Union Offices, Vauxhall Road, Birmingham.

Bradford Children's Hospital.—House Surgeon. Salary £100 per annum. Applications to C. V. Woodcock, Secretary, Bradford.

County of Lanark.—Middle Ward Isolation Hospital.—Resident Physician. Salary £140 per annum, with board, &c. Applications to W. E. Whyte, District Clerk, District Offices, Hamilton.

Stockport Union.—Stepping Hill, Hospital.—Resident Assistant Medical Officer. Salary £130 per annum, together with furnished apartments, rations, &c. Applications to C. F. Johnson, Clerk to the Guardians, Union Offices, Shaw Heath, Stockport.

County and City Infirmary, Waterford.—House Surgeon. Salary £100 per annum, with board, &c. Applications to E. O'Farrell, Secretary. (See advt.)

Fermanagh County Hospital.—House Surgeon. Salary £52 per annum. Applications to C. Wilson, Secretary. (See advt.)

Appointments.

HAMMOND, E. A., M.D., C.M., Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square, London.

KENNEDY, EDWARD, L.R.C.P. and S.Irel., Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square, London.

MCGLASHAN, J., M.D.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Newhaven District for the county of Sussex.

MCQUEEN, J., M.B., Ch.B.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Cumnock District of the county of Ayr.

NUTTALL, G. H. F., F.R.S., Quick Professorship of Biology at Cambridge University.

ST. JOHNSTON, T. R., M.R.C.S., L.R.C.P., L.S.A., Second Resident Medical Officer to the Lewisham Infirmary.

THOMPSON, A. G., M.B., B.Ch.Oxon., Clinical Assistant to the Chelsea Hospital for Women.

Births.

HART-SMITH.—On Oct. 16th, at 21 Adelaide Road, Brockley, S.E., the wife of Humphry Morshead Hart-Smith, M.B., B.C., of a son.

WILSON.—On Oct. 18th, at Denham House, Goldhawk Road, London, the wife of James Wilson, M.D., of a son.

Marriages.

HEWETSON—BUSE.—On Oct. 17th, at St. George's, Hanover Square Captain Henry Hewetson, R.A.M.C., fourth son of the late Rev John Hewetson, formerly Vicar of Measham, Leicestershire, to Margaret Elizabeth, eldest daughter of the late Henry Buse, Esq., of Bristol.

HOWES—TIBBITS.—On Oct. 18th, at St. Mary's Church, Warwick, the Rev. Richard Howes, only son of the Rev. W. A. Howes, of Cold Higham Rectory, Northamptonshire, to Ida Jane, second daughter of the late Dr. and Mrs. Tibbits, of Warwick.

Deaths.

CHEYNE.—On Oct. 17, at 38 Colby Road, Upper Norwood, William Romley Cheyne, M.R.C.S., second son of the late Robert Romley Cheyne, F.R.C.S., of 27 Nottingham Place, London, aged 58 years.

MACLEAN.—On Oct. 19th, at 10 Widcombe Crescent, Bath, John Lindsay Maclean, M.D. (of "Echoes of Service"), aged 75 years.

SIDDALL.—On Oct. 19th, at Coaybeare, Northam, Devon, Mary Elizabeth, wife of Joseph Bower Siddall, M.D., C.M., D.P.H.Cantab., late Physician H.B.M. Legation, Japan, aged 62 years.

WOOKEY.—On Oct. 20th, at 20 Moor Mead Road, St. Margaret's, Middlesex, James Wookey, M.R.C.S., L.S.A., late of Potter's Bar, Middlesex, aged 73.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, OCTOBER 31, 1906. No. 18.

NOTES AND COMMENTS.

Manchester Midwives.

IT has never been denied by the medical profession that the midwife, if she is to become a part of the medical service of the country, should be educated. It has always been strenuously asserted that the wrong way to educate the midwife is to make her an independent practitioner. Perhaps no medical prediction has so surely and so rapidly been fulfilled as that the registering of free and independent midwives would do little for the poor mother, and most of that little bad. We note that in Manchester for the first nine and a half months of this year there have been no less than thirty-four cases of puerperal fever in the practice of midwives and eight deaths. Is that an indictment of the system? No, say the midwife's backers, it is an argument for it; last year for the same period there were forty cases with twelve deaths. One cannot help remembering that the notification depends on the diagnosis of these highly-trained professional workers.

X-Rays and Sterilisation.

IN speaking of sterilisation in connection with X-rays it is not meant to attribute the bactericidal virtue to the many already possessed by the beams that issue from the Crookes' tube. It is the other kind of sterilisation that is intended; the sterilisation of the mammal. Dr. Martin, the Medical Officer for Health for Gorton, is reported to have lectured recently on the necessity of limiting the families of the fit and obviating the occurrence of families to the unfit. The Psalmist, said Dr. Martin, had remarked that the man was happy whose quiver was full, but to-day it was the parent who quivered at the responsibilities of child-rearing. But to the lunatic, the degenerate, and the diseased, though Dr. Martin would allow a quiver, he would keep him by a judicious administration of X-rays from replenishing it. "The gathering," we read, "comprised both sexes."

Vegetarian, Fruitarian, or What?

THERE are so many people alike in the world that when a man is frankly eccentric there is a good deal to be said for encouraging him. What could be more charmingly refreshing than that Mr. Eustace Miles should write to the *Daily Express* to suggest that some enthusiast should offer a prize of £100 for a satisfactory name for the diet advocated by himself? If Mr. Miles wants a good advertising name for his nuts and biscuits, surely it would not be a bad plan if he offered the £100 himself. Why "some enthusiast"? Why not, one wonders, one of the advertising staff of the *Times*? We shall make no charge for commission if our suggestion results in business.

Our Suggestion.

BUT surely it cannot be so hard to think of a name for this Milesian diet when every other hoarding flaunts the fancy nomenclature of some fresh albumino-phosphate or reduced ox. We are not quite sure what distinguishes Mr. Eustace Miles' particular diet from that of the common or garden vegetarian, but presumably he eschews fish, flesh, and fowl, and advocates some mixture of his own. Being a classical scholar he would probably object to the term "carnophobia" as being a hybrid, and Miles' food would be too much like Milo food, but we would venture to suggest that it might be appropriate to speak of his followers as suffering from "Eustachian stenosis of the diet." If he cares to award us, £100 for the suggestion, we shall be happy to hand it over to the King's Hospital Fund.

Motor Buses and Nervous Exhaustion.

A medical correspondent draws the notice of a lay contemporary to the effect that the driving of motor buses has on the nervous system of the driver. According to his statement the continuous tension created by fear of accident, combined with vibration of the vehicle, gives rise to a form of nervous exhaustion, accompanied with intense fatigue. Yet the subjects cannot sleep properly, and what rest they obtain is broken by nervous starts. We should be interested to hear if any of our readers have noticed similar phenomena in the employés of motor-bus companies. In one case brought to our notice a gentleman, after three narrow escapes in a London street within the space of half an hour, became so nervous that he found himself running across the roadway although no vehicle was near.

Is Mrs. Eddy Ill?

IF Mrs. Eddy is really seriously ill, as is currently reported in America, one would sympathise with her as with any other victim of disease. But one of her followers in denying the report says she is a "surprising illustration of longevity." If, however, illness is merely a falling away from the faith, the only surprising thing is that the leader of "Christian Science" should ever suffer or grow old.

LEADING ARTICLE.

THE HARVEIAN ORATION.

THE Harveian Oration for the year 1906 will be memorable as a display of ripe erudition and wise insight into the evolution of the human intellect. It was delivered by Dr. William Osler, who brought to the task a mental equipment peculiarly fitted for its successful treatment. Year after year the annual panegyric upon Harvey and his great discovery has taxed the ingenuity of the keenest minds in the medical profession, and the time has long gone by when it was possible to say anything new upon the man himself. His great work, however, remains a monumental work for all ages. Inasmuch as the discovery of the circulation of the blood laid the foundation of all modern pathology, the Harveian lecturer, by a judicious application of that truism, is enabled to review the whole field of medical progress. One of the keynotes struck by the Lecturer of 1906 is tersely expressed in the remark of Locke, himself a physician, to the effect that "Truth scarce ever yet carried it by vote anywhere at its first appearance." The frame of mind that three hundred years ago for a time overwhelmed Harvey with a flood of neglect, ridicule, and contempt has hitherto been the rule in the history of scientific achievement. In the present generation two striking instances may be cited in the widespread opposition which met Koch's discovery of the bacillus of tubercle and Lister's aseptic surgery. As Dr. Osler pointed out, both these truths were in the latent possession of scores of workers, but it remained in each case for the genius of a single mind to evolve the brilliant demonstration. At the same time he added the comforting reflection that the times are changing with regard to the receptivity of fresh discoveries. In support of that proposition, he contrasts the cordial welcome of the pallid spirochæte with the chilly reception of the tubercle bacillus. "We are better prepared to-day, and a great discovery like that of Shaudinn is immediately put to the test by experts in many lands, and a verdict is given in a few months. We may have become more plastic and receptive, but I doubt it; even our generation—that great generation of the last quarter of the nineteenth century—had a practical demonstration of the slowness of the acceptation of an obvious truth in the long fight for the aseptic treatment of wounds." Receptivity of new ideas, indeed, becomes difficult to most men after attaining middle age, and it is difficult to estimate the amount of mischief done by those in authority who still cling to the erroneous views of their earlier life. The progress of truth is slow, but in the end its triumph, in spite of all difficulties, is inevitable, a statement that applies to all spheres of human activity. This slowness of general acquiescence has probably proved fatal to many a great intellect, with all the finely-tempered and emotional qualities that as a rule accompany genius. In presenting a graphic picture of Harvey's life, the lecturer threw into high relief the blindness to things at their feet that may affect even the most illustrious observers. This tendency is illustrated in the case of Harvey himself by his refusal to recognise the truth of the lymphatic circulation. No less interesting is the failure of so acute a man as Fabricius, an enthusiastic teacher and investigator, to grasp the inwardness of the study on which his pupil, Harvey, was destined later to found an undying reputation. The mystery of this oversight is expressed by Dr. William Osler in the following fine passage. "How Fabricius, a man who did such work—how a teacher of such wide learning and such remarkable powers of observation, could have been so blinded as to overlook the truth which was tumbling out, so to speak, at his feet, is to us incomprehensible. But his eyes were sealed, and to him, as to his great predecessors in the chair (at Padua), clear vision was denied. The dead hand of the great Pergamite lay heavy on all thought, and Descartes had not yet changed the beginning of philosophy from wonder to doubt." There can be little doubt that many such mysteries await the evolution of medicine into the position of even a fairly exact science. Meanwhile it would be well to apply the moral of the Harveian orator, and to ask ourselves from time to time whether we may not be rejecting obvious truths and closing our ears to the gospel of unrecognised prophets in our midst.

NOTES ON CURRENT TOPICS.

Medical Service in the Field.

The recent experiment at Bulford in the shape of a camp of instruction in field hospital work, under the direction of Colonel Dundon, will we hope lead to more extensive work of the same sort. It has become a platitude to remark that in a campaign disease is more to be feared than the enemy. It is, however, matter for rejoicing that the Army authorities seem at length to recognise this. Precautions against disease must, of course, come in the first instance from the medical officers, but it is essential for their success that the strictest hygienic regulations should be drawn up, breach of which should be regarded as a serious offence against discipline. It is necessary also that combatant officers should not only receive but accept advice from medical officers as to the site of a camp; and that, unless it be unavoidable, no camp should be occupied for longer than a fortnight. Colonel Dundon's camp at Bulford, however, was more particularly concerned with instruction in ambulance work, which also stands in need of much improvement. At present, when a man falls he is carried off by three or four of his comrades, thereby weakening the firing line to a considerable extent. Any method, therefore, which renders more rapid the removal of the wounded from the field will help forward the efficiency of the army as well as to the cause of humanity.

Convalescent Homes in London Parks.

The question of devoting the empty mansions situated in the London public parks to a beneficent

purpose of providing convalescent homes has frequently been discussed, and the London County Council has always expressed itself in favour of such a scheme. The rebuff, therefore, administered by the Parks Committee of the Council to an influential deputation who recently waited on them in connection with this matter came rather as a surprise. The deputation representing the Convalescent Homes Association, led by Sir William Church, asked that the house at Golder's Hill might be given over for use as a convalescent home for children. In reply, the members of the deputation were told that the first floor of the mansion, the best part of a very fine house, was let at a rental of £15 a year! It is intolerable that a nominal sum such as this should block an important humanitarian scheme, and it is doubtful whether the County Council were even aware of the letting of the house. In fact, the transaction seems to have been smuggled through the Council in a peculiarly shady manner. The matter is all the more inexplicable as some time ago the Parks Committee recommended to the Council "that any houses and mansions in the Council's parks which are suitable for the purpose should be allowed to be used as convalescent homes." We trust that the letting of the house at this absurd sum will soon come to an end, and that a boon may then be conferred on the sick children of London.

French Minister of Public Health.

Among the things they do better in France is to welcome to their legislature medical men and medical views. It is possible in France—indeed, it is far from uncommon—for medical men to carry on a life of public political utility, whilst with us only a few academic medical representatives or men of means are able to do so. Moreover, medical men here necessarily enter political life late, and therefore seldom have a chance of attaining more than very minor posts of influence in the Ministry. In France, on the contrary, a medical man has actually been premier, and the Ministry generally includes one or two representatives of the profession. One is not, therefore, surprised to find that M. Clemenceau's new Ministry have already created a new office, that of Minister of Public Health and Labour, such as is urgently needed in this country. Not till there is a Minister specially charged with public health functions can we expect the subject to assume the full importance it deserves, and in the present case in France its conjunction with Labour forms a happy illustration of how closely the science of hygiene is bound up with the well-being of the working classes. Indeed, to the credit of the Labour Party in the present House of Commons may be attributed their zeal for the medical inspection of school children and cognate reforms.

Derby Guardians and Vaccination.

As we recently anticipated, the Derby Guardians have received a well-merited snub from the Local Government Board. The Guardians, it may be remembered, were called upon to appoint a new vaccination officer, and they took the opportunity to make it a condition of appointment that no prosecution of defaulters should be undertaken except at their initiative, and it may be guessed how often that initiative would be taken. This power of initiative was wisely reserved by the legislature for the Local Government Board, perhaps the only wise thing about the Vaccination Acts. At any rate, the Guardians at Derby have received a letter from the Board saying that the condition demanded of candidates for employment is illegal, and that they therefore decline to sanction the appointment of the officer selected. There will therefore have to be a new election, with its consequent trouble and expense, and if the same officer is elected again under the new conditions it is highly likely that the Local Government Board may again demur. Those who dislike a law would consult their own dignity and the public interest better, either by not seeking election to Boards charged with its administration, or by divesting themselves of their prejudices when placed in authority.

The Cost of "Fever."

The economic aspects of disease are far from being recognised at their proper value. The cost of preventable maladies falls not only upon the individual, but also upon the community, which in the long run has to bear the loss inflicted by the crippling and death of its citizens. Hence money paid for sanitation—which in its essence is the same as prevention of unnecessary disease—represents a sound investment by way of insurance premium paid by the ratepayers. In the municipal elections now going on throughout the kingdom many arguments have been advanced by persons who fail to grasp the first principles of public health expenditure. In the case of the Metropolis, for instance, it is shown that while the County Council and other local bodies have during the past three years spent something like £70,000,000, much of it in enforcing sanitation, nevertheless the Metropolitan Asylums Board has during that period spent nearly two millions upon fever. The obvious answer is that had the splendid service of the Board not been available for the isolation, disinfection, and treatment of Londoners suffering from infectious disease, the total loss to the community would have been infinitely greater. It is possibly the best investment of the whole £70,000,000.

The Midland Medical Union.

The pernicious effect of contract or club medical practice upon the medical profession has long been recognised. If protest take no stronger form than pious resolutions, however, things are likely to go on indefinitely in the same unsatisfactory manner. The Midland Medical Union have resolved to strike for themselves, and if the local profession can for once be induced to act in unison they should be able to control the situation. At a recent meeting the Union unanimously adopted the following reso-

lution :—"That it is desirable in the interests of the profession that immediate steps be taken for the formation of a public medical service on the following lines :—(1) To provide attendance for those members of the community who are not in a position to pay ordinary medical fees. (2) The service to be under the entire control of the medical profession in the district. (3) The service to be open to every medical practitioner in the district who so desires, provided he holds no 'private medical club.'" If carried into practice this will mean that the clubs will be under the control of medical men instead of lay committees. Obviously, if medical men act together they can boycott the clubs and friendly societies in the supply of qualified practitioners. The only danger is the presence of medical "blacklegs" who will accept appointments independently. Meanwhile, the Midland experiment is of supreme importance to the profession, which would do well to bear in mind more generally the old motto, "God helps those who help themselves."

Violet Leaves and Cancer.

THERE can hardly be a more distressing sight to the humane medical man than the spectacle of patients suffering from cancer falling into the hands of quacks. Among the host of so-called "cures" that have been foisted upon the public from time to time no single one has hitherto withstood the test of scientific examination. Among other fantastic remedies violet leaves have had their day and are still being exploited as a commercial asset by charlatans in various parts of the kingdom. The medical profession have unanimously rejected the idea of there being any virtue in violet leaves in the treatment of cancer. That their view is founded upon knowledge is shown by the fact that the chemistry of violet leaves has been thoroughly investigated by Whippell Gadd and others. Yet only a week ago a reported cure of cancer by violet leaves, "internally and externally," ran the round of the papers. The tale presents the usual fallacies. A Liverpool medical botanist treated a lady for alleged cancer of the breast, but there is no scientific proof that the disease was actually cancerous. Secondly, the growth was said to have sloughed out, leaving a healthy cavity. Thirdly, the patient, although improved, is not well. That an unqualified person should be allowed to inflict such cruelty and defraud the public in this way forms a scathing commentary upon the worthlessness of the Medical Acts so far as the protection of the community from ignorant medical practice is concerned.

Naval Medical Service.

THE Naval Medical Service must come into line with the Army. It took the medical profession some ten years to convince the nabobs of the War Office that if educated gentlemen were required for the Army Medical Service it was necessary to pay them for their education, and to treat them like gentlemen. The Navy, which was a distinctly better service than the Army, has now been left behind by the latter, that is, as far as attracting good candidates for its medical department is concerned, and the Lords at Whitehall must look to it that they bring their regulations into line with those of the junior service if they wish to provide their officers and sailors with the best care in times of war and sickness. The stirring address of Sir Lambert Ormsby which we recently published has begun to produce effect, for in last week's *Naval and Military Record* his criticisms are discussed seriously, and to some extent sympathetically. For instance, that journal agrees that it is not unreasonable that medical officers should claim to sit on courts-martial which try offences alleged against surgeons, and it emphatically associates itself with the claim that medical officers should have disciplinary power over hospital and sick-berth staffs. It considers, too, that more surgeons should be passed through the hospitals, instead of the latter employment being reserved for certain individuals to the exclusion of others—a point strongly insisted on by Sir Lambert Ormsby. On the other hand, the *Naval and Military Record* considers that other grievances mentioned are either imaginary or not capable of being rectified, and it concludes with a regret that Sir Lambert should advocate boycotting the service till justice is done. But can the journal point out any other effective method of accomplishing our determination? If so, the profession would be glad to adopt it, but its past experience in dealing with the Army has taught it that "peaceable persuasion" is an unserviceable weapon.

Public v. Fees

To part with money is to some people as hard as to part with life itself; indeed, it happens not infrequently that they seem to set a higher value on their money. Few practitioners have not had the experience of piloting a man safely through a severe illness, only to find their bill conveniently shelved when the time comes to pay. A glaring case of this ineffable form of meanness was shown up at the Clerkenwell County Court last week, when Dr. Douglas Gardiner, of Muswell Hill, sued John Maccoy, engineer and shipowner, of Gateshead-on-Tyne, for £31 15s. 6d. for medical attendance and medicine for his son. It seems that the latter was staying in lodgings near Muswell Hill and was taken ill with abscess of the liver. The illness was a desperate one, and by the care and skill of Dr. Gardiner and Mr. Cantlie, who was called in to operate, the son's life was saved after many weeks' illness. Dr. Gardiner was indefatigable in his attention, visiting the patient as often as two or three times a day, and spending hours dressing his wounds and attending to him. On the son's departure he sent in an account to the father for the exceedingly modest sum mentioned, and received a reply that he (the father) could take no responsibility in the matter. As the son had no money this was tantamount to saying that Dr. Gardiner could whistle for fees, so he promptly brought a County Court action to decide the matter. The defence was simply that the father was not liable, no suggestion of

improper treatment being made. The jury found that the father was liable, and judgment with costs was entered for the plaintiff. We heartily congratulate Dr. Gardiner on his success, and we trust that the action and its result will become known in Gateshead, so that his fellow-citizens may become aware of this shipowner's incredible meanness.

The Despotism of Doctors.

From the Queen's Square Club, W.C., there issue from time to time extraordinary theories and doctrines, but last week came forth a lecture by a Mrs. Fagan, which for inflated nonsense, one would imagine will hold the field for a considerable time. The subject was "The Despotism of the Medical Profession: A Growing Danger to the Public." Some of the more reptilian "rags" have an offensive way of referring to the "tyranny" of doctors, but we have never quite discovered wherein this tyranny lay. If it is tyranny to give advice, the world must be populated with tyrants, and only the most ignorant or sarcastic of people could imagine that the legal powers of the profession were other than a not very polite farce. However, Mrs. Fagan has enlightened us, or rather informed us, for we cannot say that we are much wiser after all. The "despotism" is not of the individual, but of the profession as a corporate body, which presents a "solid front of unanimity." Doctors "never differed from each other's expressed opinions," said this lady. We cannot help being glad that someone at last has been found bold enough to assert that doctors do not differ; so sick are we of hearing the opposite urged with wearisome reiteration. Mrs. Fagan then shows her hand. These terrible doctors—corporately, that is, not individually—have opposed the higher education of women, thinking it bad for future generations. Considering that medicine is the only one of the recognised professions open to women, this is rather a bad shot, but there is worse to come. "The advancement of women has been of immense benefit, and the woman of to-day is nearly an inch taller than a century ago, stronger, and not half so hysterical!" There is a time for everything, but surely the time to crow about the decline of hysteria in women comes rather badly the day after the Suffragette incident in the House of Commons. We may be old-fashioned, but in women we prefer the Georgian "vapours" to Edwardian hooliganism. But perhaps we are despotic.

Christian Science Again.

A correspondent calls attention to an inquest recently held at Hammersmith upon the body of a lady who was being attended by a "Dr." Riley, of Hanover Square. The gentleman named was a Christian Scientist, who did not believe in medicine, and who received a guinea per week for praying over deceased. In the witness-box Riley described himself as a Christian Science practitioner, whatever that may be. He gave an address at Hanover Square and another at Datchett. The letters M.D., C.S., were, he said, his registration form in Boston. He formerly held the M.D. degree of the University College of Missouri, but had been struck off the roll when he joined the Christian Scientists. We quite agree with our correspondent's suggestion that it would be desirable to ascertain the precise legal position of a man professing to practice medicine under what amounts to the assumption of a degree he does not possess. It is to be hoped that the police authorities will inquire into the matter, so that the public may at least be informed as to the value of the claims of Christian Science "practitioners." In the course of his evidence "Dr." Riley made the incredible statement that in cases of infectious disease he called in regular medical men. By the way, why should a scientist shy at fevers?

PERSONAL.

Dr. S. J. Sharkey, physician to St. Thomas's Hospital, will deliver the Bradshaw Lecture before the Royal College of Physicians of London, on Tuesday next, November 6th, the subject being "Rectal Alimentation."

It is announced that a Congress of Military Medicine will shortly be held in Paris. Its declared object is to bring the medical officers of the regular army and the all the officers of reserve into personal and scientific contact with each other.

On December 13th next a suitable entertainment festival will be held at the Philharmonic, Berlin, on the seventieth birthdays of Dr. Wilhelm Waldeger, Professor of Anatomy, and Dr. Ernst von Bergmann, Professor of Surgery, in the University of Berlin.

Professor Noel Paton, introduced by Professor Stockman, last week delivered his inaugural address in the physiology class-room of Glasgow University.

Dr. J. M. Redmond, F.R.C.P.I., was elected President of the Royal College of Physicians of Ireland on St. Luke's Day; Dr. Conolly Norman, Censor and Vice-President; and Dr. John Murphy, Dr. Henry Jellett, and Dr. R. Travers Smith, Censors.

We understand that Mr. Jonathan Hutchinson, F.R.C.S., F.R.S., has kindly placed his educational museum at Selby at the disposal of the vicar for services during the re-building of Selby Abbey, recently destroyed by fire.

Dr. Charles Dundee, of Ballycarry, was last week sworn in as a Justice of the Peace for County Antrim.

Dr. Aubrey D. P. Hodges, of Knebworth, Herts, has been presented by Prince Luigi with a gold watch for his services to his chief of staff who was stricken with fever while travelling with the Prince in Uganda. Dr. Hodges is making investigations into the cause of sleeping sickness in East Africa and the Uganda Protectorate for the Foreign Office, and so came in contact with the Prince.

The Chair of Midwifery and Gynæcology in the Cairo School of Medicine has been offered to Dr. Roy Dobbin, Assistant Master at the Rotunda Hospital, Dublin. The selection of Dr. Dobbin from a large number of candidates from all parts of the kingdom is a compliment to the Dublin School of Midwifery.

Sir Christopher Nixon, Bart., M.D., has been appointed Vice-Chancellor of the Royal University of Ireland in place of the late Monsignor Molloy.

A CLINICAL LECTURE
ON
URETHRAL IMPEDIMENTS TO THE EVACUATION OF URINE. (a)

By R. F. TOBIN, F.R.C.S.,

Surgeon to St. Vincent's Hospital, Dublin.

GENTLEMEN,—Clinical teaching, I take it, consists not in communicating to men classifications of ascertained facts, but in showing them how to work, and in encouraging them in the making of original observations, and in independent reasoning on such premises. It is a process in which the willing co-operation—perhaps ardour would be a better word—of the student is essential. What do you do when you want to teach a puppy to hunt rats? You take the cub with an old "ratter" to a place where a rat has been seen, and you pat him on the back, saying, "Good dog! good dog!" It is even so with clinical teaching. One can only take pupils to the patient, give them a few words of encouragement, and at times join in the hunt to show them how the thing is usually done.

I shall proceed with the two cases before us. In each there is some impediment to the evacuation of the bladder. A. is a man of 60, a farm labourer. For two or three years he has had frequency of micturition. He tells us that he empties his bladder, or supposes he does, on going to bed, but notwithstanding, in an hour or two he is awakened by a want to micturate. The call is repeated a couple of times before daybreak. The frequency is not so troublesome during the day. Now for the physical examination of him. I make a digital exploration of the rectum while he leans over and supports himself by the back of a chair. For present purposes I look on the front wall of the rectum as the back wall of the bladder and urethra. The prostate is considerably and uniformly enlarged. It gives a feeling of resiliency rather than hardness to the touch. The lobes are not distinct; they seem pressed into one; the finger cannot reach their upper edge.

I now ask him to make water. You see he has difficulty in starting it, and now, although he is straining, it does not come in force, but dribbles from the end of the penis. He tells us that he has emptied his bladder—he is sure of it. To see whether he has or not, I draw on these aseptic gloves, and having cleaned the orifice of his urethra—the urethra itself, remember, has been washed (a most important point), in the only way it can be properly washed, by water from the bladder—I pass this recently boiled soft rubber catheter, and at a distance of eleven inches I draw off an even larger quantity of urine than that which he has passed. It is about six ounces. I put both specimens aside to be fully examined in the laboratory.

We now pass to case B. He is about 35. He tells us that he had gonorrhœa when he was 19, and that it lasted on him a long time. A few years later he noticed the stream growing small and irregular in shape, and now he has difficulty at times in passing water at all. He will do so before you. You see it shoots out with some force in a small stream like water under high pressure from a small leak in a pipe. There is almost certainly a stricture. Passing down this gum-elastic sound, the bulbous point of which is in size No. 3, and larger than its stem, I meet with a constriction, through which I can coax it, and which by passing the bulb backwards and forwards I can define to be a band about the eighth of an inch broad at a point on a level with Cowper's gland. When the patient had gonorrhœa years ago, there was, no doubt, ulceration at this point, and the resulting cicatricial tissue laid the foundation of the trouble.

Now in these two cases we are face to face with the chief urethral impediments to the evacuation of the bladder. They call for attention on account of the inconvenience complained of by the patients, on account of the danger of complete retention, and because all impediments to the escape of urine by the back pressure they exercise on the kidneys tend from the outset to interfere with their function, and finally bring about their complete disintegration. It is from the kidneys' point of view that we will consider these cases to-day. It is the most important, and the one most likely to be overlooked. The other aspects advertise themselves. Here are kidneys picked up by me in various parts of the world of men who suffered from impediments to the escape of urine. Look at them carefully, and let them teach their lesson.

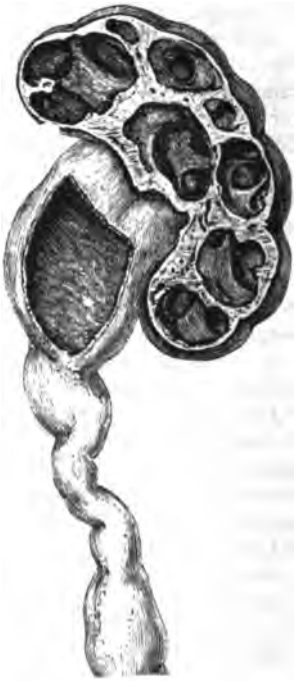

FIG. I.

This is a clinical lecture, and any dissertation on the process by which such changes as those before you are brought about would be out of place. You must study them in works on pathology. May I recommend you one work in particular?—Cohnheim's "Lectures on General Pathology." There is an excellent translation of them by the late Dr. McKee in the Sydenham Series. He is the most interesting of teachers. He takes you along with him. You are pleased as you go; and if you pause and ask yourself why, you will find it is because you have been thinking the whole time, and in the most excellent fashion. Progressive thinking, like progressive jumping, is exhilarating. Supposing such reading done, what will you hear the kidneys saying as to treatment? Only these few words—"Remove the impediments at once."

In a case of stricture it is, as a rule, quite easy. I'll do it for this patient painlessly in a few minutes,

(a) A Clinical Lecture delivered to Senior Students at the Hospital.

with the help of a little cocaine, a Maisoneuve's urethratome, and a No. 12 silver catheter. (Operation performed, and stress laid on the way the knife should be withdrawn if it has been allowed to enter the bladder. In such case only by pressing it back against the posterior wall of the prostatic urethra can it be prevented hitching at the neck of the bladder and making an unnecessary wound.) If this patient will now pass every Saturday night the 9 to 12 Lister's sound, which I'll teach him to use ere he is discharged, the impediment to the evacuation of urine is, in his case, gone, never to return.

In the other case the obstruction is, as we have ascertained, of a different kind. In it the enlarged prostate, by a valvular action, interferes with the discharge of urine. Here is a prostate which you saw me remove in this theatre a month ago. (Fig. II. and Fig. III.). An outgrowth from the middle lobe, or more properly from the middle portion, falls over the outlet of the bladder, and in this instance fits it accurately like the cover of a snuffbox. Pressure, you see, from within the bladder only forces down the lid; pressure on the urethral aspect raises it.

Fig. II

Fig. III.

If you will now examine carefully these specimens of hypertrophied prostate which I hand round (many of them are in sections to facilitate examination), you will notice that the growth has so affected all the structure, including the urethra, that in any removal all must come away together. Further, if you will look at this, the last specimen I'll submit to you (Fig. IV.),

Fig. IV.)

you will see that the change has arranged the tissues in onion-like layers, making enucleation as a rule easy, and, as it were, asking for such interference. Again, in this case, we ask the kidneys, "What is to be done?" Of course, they again say "Remove the impediment." But the job is not an easy one, and not unaccompanied with danger to life, so we must pause. I have no doubt as to its being the treatment that furnishes the largest number of comfortable days and comfortable nights. That is, if A. were to take all cases he met with suffering from urinary troubles owing to senile hypertrophy of the prostate, no matter at what stage, and enucleate the obstacle, and the cases amounted in number to one hundred; and B. were to treat the first hundred cases that came his way by other methods, the years of life falling to A.'s patients in the aggregate would exceed the number falling to B.'s, and if before the word "life" you introduce some such adjective as "comfortable" or "efficient," then the comparison would be still more in favour of A. But, while this is so, there stands out the fact that no major operation is devoid of risk when the kidneys are not sound, and many a patient will say, "What are your averages to me if I chance to be amongst the victims of your heroic procedure?" You must, therefore, use no cocksure rule in dealing with such cases, but, after fully explaining matters, leave a great deal to the discretion of the patient, who knows better than anyone else the extent of his trouble and the conditions that for him make life worth living. Prostatic cases, as they present themselves, may, I think, be considered in three classes:—(1) Those in which there is slight enlargement, with urinary trouble amounting to about two calls at night and two ounces of residual urine. Such cases are, I think, as a rule, best left alone, and kept under observation, the patient being instructed as to what are irritants to the prostate—alcohol, riding, chills, long sittings, etc. Enucleation at such a stage presents more difficulties than it does later on, and as there is always some danger of sepsis from catheterism, it is a question whether the amount of residual urine warrants such risk. If the patient were very urgent to have something done, I would consider the advisability of vasectomy, provided it were a case where the effects of that operation on procreation could be left out of count. That it is prophylactic there can be no doubt; it is, moreover, perfectly safe, detains a patient only a few days in hospital, and no patient on whom I have performed it ever noticed any change in his general condition of mind or body. (2) Patients seriously incommoded by urinary troubles, and with fairly large prostates, and residual urine in excess of the quantity mentioned above. For such cases enucleation is certainly indicated, and should be recommended. It is a well-established operation, with a mortality, in experienced hands, of not more than 10 per cent., and one which changes an ever-increasing

condition of suffering into one of healthful life for those on whom it is successfully performed.

The patient before us is willing to be operated on; he is in every way a suitable case; so to-morrow I will be able to give you a practical demonstration of the steps of the operation.

Those who will not consent to operation must be content to enter on catheter life, with its dangers of sepsis, cystitis, unmanageable retention, and deteriorating kidneys.

(3) To this class belong patients who, after years of discomfort, or maybe of much suffering, with kidneys such as those I have shown you, with sacculated, half-emptied bladders and a condition of the prostate making catheterism difficult, seek surgical advice. What is to be done for these?

Often, in consultations on such cases, when I propose operation, I am met with the remark, "But the kidneys are very much affected." To this I answer, "Yes; but the operation is for the relief of the kidneys. It will drain them as effectually as if the incision engaged themselves." Whoever has made many post-mortem examinations on men with surgical kidneys must have been struck with the small quantity of kidney substance with which a man can carry on and do good work. You may remember the case of a sailor who died here lately, who had been working up to the date of his admission, and of whose kidneys there was little but capsule left. You should bear these points in mind, and, so influenced, you will, I believe, in most cases proceed to prostatectomy or at least drainage of the bladder through a suprapubic opening. About the carrying out of this latter procedure there should not be the least hesitation when in a chronic case great difficulty is met with in passing a catheter. With a hyper-distended bladder it is the easiest of operations. In the median line above the pubis, duly shaved and cleansed, you inject a little cocaine, carry a two-inch incision through the skin, and then, with a blunt dissector, between the recti muscles work down till the bladder is reached. If in doubt as to direction, pass one hand with a glove on into the rectum and work towards it. The bladder being reached, you, standing on the left of your patient, pass a fully-curved needle through a point a quarter of an inch from the centre of the right lip of the incision you have made down through all the tissues into the bladder and then up through a similar line on the opposite side. With a hyper-distended bladder this is a proceeding of no difficulty. You now open the bladder, still using the blunt director, which, without injury to distended veins, goes easily through its muscular walls. With your finger you hitch up out of the bladder the suture just passed, and having divided it, tie each thread on each side. This establishes a clear way into the bladder, no matter how it may contract, and does away with one of the chief dangers of suprapubic cystotomy, the making of false passages in passing drainage tubes and in making examinations subsequent to operation. This procedure, including the washing out of the bladder with boric acid solution through a drainage tube of a size to fill the opening made, need not occupy more than ten minutes.

Your patient is now safe. His kidneys are relieved from all pressure, the urine can flow freely, and there is time to pause to see how he gets on, and to decide whether it is well to do anything further or not. If, when the kidneys have settled down under the new conditions, you find by an examination of the urine that there is some kidney substance still in existence, you will no doubt complete what you have done by an enucleation of the prostate. If, on the other hand, he is beyond such operation, what you have done for him will, when he is provided with a suitable tap and urinal, give to his remaining days as much comfort as they are capable of.

I have put this small operation in detail before you because at first sight it seems more formidable than it is, and it enables a man in a remote place who has no assistant and but few appliances to deal with complete retention of urine from prostatic disease—a not uncommon emergency—in the best possible way, and in doing so make an excellent half-way house on the way to a complete measure.

A Clinical Lecture by a well-known teacher appears in each Number of this journal. The lecture for next week's issue will be by the late Professor Potain, of the University of Paris, on "Latent Diseases." This lecture was almost the last academic utterance of the late distinguished physician, and has not previously appeared in print, having been specially reported for this journal.

ORIGINAL PAPERS.

ON COMPRESSION PARAPLEGIA, WITH A CASE OF REMOVAL OF TUMOUR FROM THE CAUDA EQUINA.

By W. B. WARRINGTON, M.D., LOND., F.R.C.P.,

Physician to the David Lewis Northern Hospital; Lecturer on Neuro-Pathology, University of Liverpool.

THIS subject includes a group of diseases which have much in common, and whose therapeutics are based on similar principles. (*a*) In every case of paraplegia the first duty is to ascertain if pressure be a cause, and if so, to locate its site and determine its nature. A correct and precise diagnosis is essential, and stimulated by this necessity a remarkable knowledge of at least the grosser functions of the spinal cord and its individual segments has been gained.

Successful treatment is based on primary facts in physiology and pathology. There is no evidence that repair of cells or fibres ever takes place within the central nervous system. Growth there is, but not birth.

The last impressions which fall upon the sentient cortex of the brain are reflected from cell to cell, harmonised by association of fibres, and traverse the paths of a system whose elements were present at birth. Hence it follows that damage once done whether by the experimenter's knife, by syphilis, or in any other way, is irremediable.

To balance against this is the multiformity of representation of physical actions in the nervous matter. Section of one posterior root produces no enduring anæsthesia, yet that involves the extinction of function of 10,000 cells or more, which compose a spinal ganglion.

Considerable masses of substance may be removed from parts of the brain without any appreciable result, aud degeneration of some fibres in the pyramidal tract occurs without perceptibly modifying movement. Lastly, nervous tissue itself is resistant to disease in a degree exceeding that of other tissues. Of the large number of so-called nervous diseases, the majority are secondary to disease of the nutrient or supporting tissues, and disease may often compress nerve elements and render them incapable of function, without destroying their life, so that if the pressure is removed function may return.

Tumours in the region of the cord may have four sites, arising in the bones, the cord itself, or from the meninges, where they may be either extra- or intra-dural. As the first two are practically inoperable, my remarks will refer only to meningeal tumours. It is difficult to estimate the frequency in which the cord is damaged by tumour. Schlesinger, in 35,000 autopsies, found the cord pressed upon in 100 cases; but this record includes all tumours, whatever their origin, and tumours of bone exceed in frequency all the other forms together. R. T. Williamson has collected references to 110 cases of meningeal tumour, 58 of which were extradural, 52 intradural. Allan Starr considers that spinal tumours are thirteen times less frequent than brain tumours; in his own experience he has treated a hundred brain tumours and

(*a*) "Liverpool Medico-Chirurgical Journal," January 1906.

ten spinal tumours. From these figures it is obvious that the condition is one of considerable clinical importance, especially when it is remembered that in at least half the cases surgical treatment results in complete or marked recovery. The tumours springing from the meninges are commonly hydatid, and varieties of fibromata and sarcomata. When the latter are formed by soft, rapidly growing cells, they tend to invade the membranes and to grow round the cord, from which, however, the growth may be stripped; they infiltrate but do not often destroy the nerve-elements. Though not nearly so favourable for operative treatment as the circumscribed fibromata or hydatid, considerable success may be obtained. It is noteworthy that true gummata of the cord or of the membranes are extremely rare; so also is an isolated tuberculous growth. Neither of these conditions was found in 53 operations.

Symptoms.—The symptoms of extra and intradural tumours are practically the same, and are to be studied, as they give rise to symptoms of irritation of the roots, or interference with the function of the cord. Symptoms from irritation of roots nearly always appear first; hence pain is generally the most important symptom. Its character requires close attention. When due to irritation of the posterior roots it is referred to the peripheral distribution and may be felt at considerable distance from the site of the growth; thus, in a case of tumour at the level of the second to fourth dorsal vertebræ the pain was felt about the region of the left nipple; abdominal pain, at first thought to be flatulent dyspepsia, was the prominent symptom of a tumour at the level of the tenth thoracic segment. When in the cervical region, pain may be referred to the upper limb; in the lumbar or sacral region it radiates along the course of the nerves of the lumbar or sacral plexuses.

The pain is intense in character and often paroxysmal, and the region of the nerve root-supply may be hyperæsthetic; but it is important to note, as distinguishing this pain from that in neuralgia or neuritis, that neither are the painful points of Valleix present nor is there any tenderness along the course of the nerve. From the fact that the tumours are usually small and invade only a slight vertical extent, the pain is often limited in a very remarkable way to the distribution of one or two roots. It may last for a very long time without further symptoms, as in the famous case of Capt. G., recorded by Gowers and Horsley, where pain was almost the only symptom present for three years. Starr remarks that pain of long duration localised to one position should arouse suspicion of spinal tumour. The longer the duration before symptoms of interference with the cord itself appear, the more probable is it that the tumour is extradural and innocent in histological structure.

Sometimes the pain is not due to invasion of a root, but to irritation of the conducting tracts in the cord, and here its site cannot have the same diagnostic or localising value. Painful cramp of muscle resulting from irritation of the anterior roots is uncommon, and such spasm may be reflex. At a later period destruction of the root may take place, and if no other root were affected probably the pain would cease; but anæsthesia or paralysis and wasting of muscles rarely results from this cause.

Symptoms resulting from Interference with the Spinal Cord.

Motor paralysis always precedes sensory loss, and in the first instance produces spastic paralysis in the lower limbs. Should the tumour destroy the ventral cornual cells, paralysis with wasting would be present at that level, but this can only be noticed when the cervical or lumbar regions are the site of the growth. It is of great importance to note that the paralysis often affects one side considerably before the other; but when once paralysis is well marked it usually extends rather rapidly, so that paralysis of one lower limb is soon followed by a paraplegia. The spasticity may be intense and accompanied by violent spasms of the limbs. Sensory loss appears later, and may in some cases, when there is one-sided paralysis, be on the opposite side, giving the well-known Brown-Séquard's syndrome. Its extent on the body marks the level of distribution of the nerve root of the highest segment involved, but owing to the oblique course of the roots the anæsthesia does not correspond with the site of the tumour, which must be determined by a knowledge of the anatomical relationship between the vertebræ and the points of origin of the roots. The knowledge of the sensory supply to regions of the body is the chief guide to precise localisation, and is due chiefly to the work of Ross and Thorburn of Manchester, Sherrington, of Liverpool, Head, of London, Kocker, of Berne, and Allan Starr, of New York. I have found the diagram devised by Seiffer from studies of the work of these and other writers simple and very useful; it shows certain named lines which represent limits of root distribution fairly well agreed upon.

The time taken by this stage of cord symptoms varies much. Continued pressure may set up inflammation, causing a softening of the cord, and the terminal stages rapidly appear; sooner or later conduction ceases between the brain and cord, and often suddenly the picture changes, the spastic state gives way to flaccidity, loss of sensation becomes absolute, the reflexes, with the exception perhaps of the extensor plantar reflex, disappear, and the sphincters are paralysed. Few experiences in medicine arouse so tragic an interest—an interest intensified in many with even little physiological imagination. The patient has become the spinal man; he is indeed two bodies—one still in connection with the centres of life and sense, the other almost lifeless, save for the feeble autonomous action of the spinal cord. Not merely is the lower part of the body powerless and anæsthetic, but the functions of respiration, of the circulation, of the intestines and the urino-genital system are disordered, no longer presided over by the medulla, the most ancient hierarchy in the nervous system.

These are the striking symptoms, as first pointed out by Bastian, of a complete transverse section of the cord. Important discussions, in which most of the distinguished neurologists of the world took part, followed on Bastian's paper. After a rather extensive review of the literature of the subject, published in the *Medical Chronicle*, 1902, I concluded that if the triad of symptoms given by Bastian are present the lesion is certainly complete, but that a slow progressive damage of the cord, going on to the production of complete loss of continuity, does not result in the same symptoms as a rapid destruction of the cord. In these cases rigidity, with increase of the tendon reflexes, may be present. But I have only lately realised how often this barrier, impenetrable to nervous impulses, may be physiological only, caused by pressure, œdema, or evascularisation of the cord. Such a condition is recoverable either spontaneously or by treatment. The symptoms, as far as the nervous system is concerned, must of course be identical, and a recognition of the nature of the lesion can only be made from attending circumstances. Hence we reach the important conclusion, not yet generally realised, that, provided too long a time has not elapsed since their appearance, the triad of symptoms described by Bastian does not necessarily contra-indicate operation, but it may in fact afford the most urgent indication for interference, as in a case of caries under the care of Mr. Monsarrat, in which the spastic condition gave place within 24 hours to flaccid paralysis and absence of reflexes. The result of the operation showed that the surgeon had to deal probably with a condition in which secondary acute myelitis had destroyed all conduction, and no improvement resulted; yet the operation was justifiable, for the condition might have resulted from removable pressure. A number of other cases might be cited.

Lastly, in cases of tumour, we have to consider the symptoms referable to the spine. As a rule these are not well marked, offering a sharp contrast to caries.

There is rarely pain on vertical or lateral pressure of the vertebræ, though some tenderness to percussion may be present over the site of the tumour, and the spine may be sensitive to heat and electricity. These symptoms and the slight rigidity which is often present are probably due to the irritation of the nerves supplying the dura mater.

If the symptoms of gradual invasion of the cord, in the order stated, are present, a tumour is highly probable. In differential diagnosis certain conditions must be excluded :—

1. Tumours of the spine itself, indicated by signs of disease in the bone and the great severity of pain on movement.

2. Caries—here kyphosis and rigidity are especially important; the root pain is not so severe, and constitutional symptoms or evidence of disease elsewhere are present.

3. Syphilis. Gumma is so extremely rare that it should not be diagnosed and precious time lost unless there is a definite history of infection. Chronic meningitis is not uncommon and might give rise to doubt, but here the distribution of symptoms is more random, their vertical extent greater, the cord is rarely much affected, and cerebral symptoms may be present.

4. The hypertrophic form of pachymeningitis described by Charcot has been diagnosed as tumour of the cord. The essential points of distinction are that this condition produces bilateral symptoms from the first, and their vertical extent is greater.

5. I should mention chronic myelitis. A chronic primary inflammatory lesion of the cord should not be diagnosed unless all other diseases are excluded. I submit that the greatest caution is necessary in making this diagnosis; even if the possibility of such a pathological process is admitted, it is most rare. Pain, if present, would be less severe than in tumour. The pain of tumour should not be mistaken for neuralgia or simple neuritis if a reasonable time has been given for observation, and the constant presentation of the same picture has not blunted the alertness of the physician. I may here quote the words of Allan Starr: "In no other disease of the spinal cord do the symptoms of transverse myelitis of gradual onset coincide with the symptoms of persistent pain."

A CASE OF TUMOUR OF THE CAUDA EQUINA.

(*a*) The patient, G., a laundryman, æt. 36, was admitted on August 4th on account of pain in both thighs and weakness of the lower limbs. He had suffered from the pain for about five months; loss of power had developed later. Four years ago he contracted gonorrhœa, followed by stricture of the urethra. On one occasion retention of urine had to be relieved by supra-pubic puncture. Beyond this no history of illness could be elicited. Syphilis was denied, and there was no evidence of it. The father had died from a tumour of the brain at the age of 56. The mother, three brothers, and five sisters are living and in good health. The patient looked ill and worn, and evidently suffered greatly; he was anæmic and somewhat emaciated; weight, 9st. 4lbs. Heart and lungs normal. Nothing could be detected on palpation of the abdomen or by digital examination of the rectum. Urine, sp. gr. 1,016. No albumen or sugar.

Pain.—Severe, spontaneous, shooting pain, often worse at night; it started about the middle line at the level of the highest part of the sacrum, passed downwards over both buttocks and the posterior surface of the thighs, and outside of the legs as far as the ankle, but did not invade the feet.

The pain was much worse when he lay on either side or on the face. It was then referred especially to the lower part of the sacrum. There was sharp pain on flexing the thigh on the pelvis (sign of Lasègue). No particular pain on pressing the muscles of the thigh or legs, or along the course of the great sciatic nerve, or at the points of Valleix.

(*a*) I am made indebted to Dr. John Owen, Medical Tutor at the Hospital, for many careful examinations of the patient.

Spinal Column.—The 1st, 2nd, and 3rd lumbar spines were somewhat uniformly prominent; no pain was caused by percussing these, or by vertical pressure, or by lateral pressure through the iliac crests. There was, however, considerable rigidity of the lower part of the spine. In bending backwards, forwards, or laterally, whilst the upper part of the spine moved, the lower portion remained immobile, and the resulting movement was one of the trunk together with the pelvis on the thighs.

Motor.—There was considerable loss of power in both lower limbs, more markedly so on the left side; inability to raise the left thigh against slight resistance; weakness in the flexors of the leg on the thigh and in muscles moving the feet, though none of these movements were absolutely paralysed. Thus there seemed to be weakness in all the muscles supplied by the lumbo-sacral plexus. All the muscles re-acted to the faradic current, and to a less extent on the left side. Plantar reflex present but ambiguous.

Bladder and Rectum.—Micturition was normal, but the patient stated that he had not as good a control over the action of the bowel as formerly; he had to go to stool quickly in order to avoid soiling himself. On examining the rectum digitally the sphincter ani contracted fairly forcibly on to the finger, and the rectum appeared dilated and ballooned. The patient also stated that he did not feel the examination.

Sensation.—There was marked loss of sensation to touch and pain in the areas figured on the chart. Light touches with the blunt head of a pin were not recognised at all, and a pin-prick was recognised as a dull, just perceptible sensation. This anæsthesia invaded also the penis and scrotum and peritoneum. Testicular sensation was preserved, but there had been neither erections nor seminal emissions for six months.

PROGRESS OF THE CASE.

In the course of a fortnight the symptoms were considerably more defined, and permitted an accurate analysis of the nervous structures involved to be made.

Motor.—The weakness was bilateral, rather more on the left side than right side. Great increase in the weakness of the movement of the feet, which soon became absolutely powerless. On the other hand, the extensors of the legs—the quadriceps group—and the extensors and external rotators of the thighs, though somewhat weaker than natural, acted with moderate force, so that the leg could be raised from the bed. Adduction of the thighs was well performed. The biceps femoris was felt to contract, but feebly. The semitendinosus and semimembranosus also contracted, and apparently not with greatly diminished force. The muscles of the legs were somewhat, but not greatly, wasted. There was no reaction of degeneration, though the faradic irritability was diminished in all the leg muscles. The ankle-jerks remained absent; the plantar reflex could not now be obtained. The left jerk had gradually diminished, and on the 29th August was absent. The right knee-jerk was brisk, and on tapping the quadriceps tendon a lively contraction of the adductors on both sides occured. Abdominal and cremasteric reflexes brisk.

Bladder and Rectum.—On the 23rd August the patient first complained of some difficulty in passing urine—he had to strain. Retention set in a few days later, necessitating the use of a catheter, which the patient was unable to feel. Enemata were required; there was also involuntary passage of fæces and total loss of sensation of the act. The anus was patulous.

Sensation.—The inner sides of the legs were now becoming anæsthetic, the area of loss of sensation in this zone being fairly well defined, and more marked for pain than for touch. The pain remained very severe, necessitating continual administration of morphine. The distribution of the roots forming respectively the lumbar and sacral plexuses is now fairly well agreed upon—the lumbar roots form the

anterior crural and obturator nerves and supply the quadriceps extensor group and the adductors of the thigh; their sensory distribution is on the front and sides of the thigh and inner side of the leg. It is obvious that in the case of G. the functions of these nerves were unimpaired, and that the lesion was one interfering with the function of the sacral plexus. Such an extensive bilateral affection, nearly symmetrical, could be explained only by a lesion interfering with the functions of these nerves either where they are situated close together, forming the cauda equina, or by implication of their centres of origin in the lowest part of the cord itself—viz., the conus medullaris. The limit of the conus has been arbitrarily fixed to include that part of the cord extending from between the origin of the second and third sacral nerves to its termination, a definition which is convenient, since it implies either a total or partial integrity of the lumbar nerves, and further, since it is a clinical fact that lesions of the cauda equina produce symptoms indicating invasion of the sacral roots. Anatomically, indeed, the cauda equina includes the great leash of nerve roots which form both lumbar and sacral plexuses; but, for the reasons just mentioned, its use clinically is restricted to the roots forming the sacral plexus.

In the case of G. the anæsthesia involved all the areas of the sacral aud the last lumbar roots, whilst the muscles belonging to the upper roots were not much affected. At a later period the appearance first of anæsthesia of the inner side of the leg and then of the loss of knee-jerk showed that the fourth and third lumbar roots were becoming involved.

The diagnostic problems were:—(1) Is the lesion in the cord, the conus medullaris, or in the cauda equina? (2) What is its nature? The diagnosis as to the site of the lesion was of great importance, for disease of the conus offers little chance to the surgeon. Here important centres are comprised in a small mass of nervous matter, and the morbid process soon produces its maximum destruction. The cauda equina, on the other hand, is readily exposed, and the nerve roots forming it may suffer only slight and recoverable damage.

The symptoms must necessarily be very similar, since the muscular paralysis, sensory disturbance, and affections of the bladder or rectum may be equally produced by a nuclear (spinal cord) or radicular lesion. The symptoms produced by lesions in either of these situations, referable to the bladder, rectum, and external organs of generation, are of high interest. It can only now be pointed out that the acts of ejaculation of semen and forcible expulsion of the last few drops of urine depend on contraction of the bulbo and ischio cavernosi muscles, which are always paralysed if the lowest part of the cord or the corresponding roots are damaged. It is therefore only by a consideration of the collateral circumstances that a diagnosis can be made. Excluding for the present traumatic lesion, the writings of Raymond and Sappy indicate the following points as being in favour of a lesion of the *roots*:—

1. An insidious onset, with gradual development and progression of symptoms. The conus medullaris gives origin, from a very small extent, to many nerves, and hence disease there is characterised by a rapid course.

2. Pain, violent in nature, spontaneous or excited by change of position or of movement, is in favour of a radicular lesion; moderate pain may be present in either condition.

3. Pain over the vertebral column below the level of the second lumbar spine, exaggerated by percussion and radiating towards the lower limbs, is in favour of a cauda equina lesion. To this I am inclined to add rigidity of the lower part of spine due to irritation of the nerves of the dura mater. Pain higher up, increased by pressure, not radiating very clearly over the lower limbs, is in favour of a medullary lesion.

The sign of Lasègue (pain on flexing the thigh with the leg extended, on to the pelvis), though it may be absent, is a further indication of a radicular lesion.

4. A symmetrical development is a radicular symptom, and perhaps especially suggestive of extradural lesion. Remission of symptoms, especially amelioration in the condition of the bladder and rectum, the slow appearance of muscular wasting, of the reaction of degeneration, and of trophic disturbance are in favour of the cauda equina.

The lesion was therefore considered to be in the cauda equina. As to its nature, it was known not to be a case of injury, and syphilitic and tuberculous processes were thought to be unlikely. The rapid and progressive march of symptoms indicated a neoplasm as the most likely cause, and the diagnosis having been made, an operation was performed by my colleage, Mr. R. W. Murray, on September 2nd, 1904. The spines and laminæ of the 2nd, 3rd, and 4th lumbar vertebræ were removed. On opening the dura mater, a red, soft-looking mass about an inch long was seen surrounded by the nerve roots. It bled very readily, but a considerable portion was removed. Subsequent examination showed the tumour to be an endothelioma or hæmorrhagic angiosarcoma. Rather unexpectedly, the patient improved considerably and regained the power of walking with the aid of sticks, the knee-jerks returned, and the anæsthesia greatly diminished. The pain also was very much relieved. Unfortunately, at about the end of three months symptoms began to return, and pain became again very severe. There could be little doubt from the histological examination that the tumour was maligant and that it had rapidly grown. A second operation was thought to offer some slight chance of relief, but on exposing the nerves it was found that the tumour had grown enormously, and was now from two to three inches long. As the condition was obviously incurable, Mr. Murray and I considered it justifiable to divide a number of the posterior roots. The patient is now completely paralysed in the lower limbs, but though pain was at first relieved it subsequently returned.

I am acquainted with the records of six other cases in which tumours of the cauda equina have been removed, four with almost complete success, one of these being recently under the care of Dr. Ferrier and Sir Victor Horsley. The two remaining, like ours, were malignant sarcomata, and in one of these the operator decided, as we did, to cut the posterior roots in order to spare the patient an agonising end.

Altogether some 26 cases of tumour of this region are known to me, many of which could undoubtedly have been successfully treated. The diagnosis of the exact site of injury in this region is also, and for the same reasons, of the utmost importance, and I quote van Gehachten's conclusions for the guidance of the surgeon:—

1. If no lesion of the vertebral column is found, it is probable that the medulla spinalis will have been injured.

2. In lesions of the first lumbar vertebra or above, the conus medullaris is alone affected.

3. Injury to the second lumbar vertebra causes damage to either the cone or cauda equina, because the level at which the cord terminates varies; in lesions of this vertebra, therefore, injury to the cone cannot be excluded.

4. Injury below this level causes damage to the cauda equina only.

We owe much to Raymond of the Salpêtrière for his work on these finer points in diagnostics and for his records of other pathological conditions affecting this region.

In conclusion, I plead for a close co-operation of the surgeon and physician in dealing with disorders of the nervous system. In no branch of medicine is it more desirable. Such a co-operation is one of the reasons why the Queen's Square Hospital has

so wide a fame, and can only result in benefit to the patient and the advancement of medicine. The science of the surgeon and the high polish of his skill make the history of his art a wonderful story. The hands of the physician are tied by tradition; but those traditions carry too the burden of *Noblesse oblige*, for he cannot be unmindful of the great labourers of the past, many of whom were physicians, who have placed the physiology of the nervous system on a secure and enduring foundation. It is fitting, therefore, that the physician and surgeon should work together in the study and treatment of these diseases.

FURTHER WORK ON THE CHEMISTRY OF VIOLA ODORATA. (*a*)

By H. WHIPPELL GADD, F.C.S.

IN a communication which I read before this Society in December of last year, some experiments were described which, although they had failed to isolate a glucoside, provided strong evidence of the presence of one, and it was presumed that this was the Viola-quercitrin described by Professor Mandelin as having the formula $C_{43}H_{42}O_{24}$.

It has since, however, been pointed out to me by Mr. A. G. Perkin, of the University of Leeds, that Mandelin's formula is incorrect, and that the correct formula for Viola-quercitrin is $C_{27}H_{28}O_{16}$.

Mr. Perkin found this Glucoside in the flowers of the Viola odorata, but in smaller amount than in those of the Viola tricolor.

At my request he has very kindly made some dyeing experiments with an extract which I prepared from the leaves of the Viola odorata, and which was calculated from its yield of glucose to contain about 5 per cent. of Viola-quercitrin ($C_{27}H_{28}O_{16}$.)

Pieces of cloth were mordanted respectively with aluminium, chromium, tin, and iron, and were then divided into two portions. One portion of each was treated with 2 c.c. of a liquid extract of violet leaves, this quantity being equal theoretically to 0.1 per cent. of Viola-quercitrin.

The other portions were treated with a solution containing 0.05 gramme of Viola-quercitrin obtained from eucalyptus.

On comparing the results, it was found that the pieces treated with the violet extract could hardly be seen to be dyed at all, whereas those treated with the solution of Viola-quercitrin from eucalyptus were coloured deeply.

It was therefore evident that there was a mere trace, if any, of Viola-quercitrin present.

All attempts to isolate and identify a glucoside from the violet leaves have failed, and no other principle has been detected.

Attempts to isolate a ferment have also been unsuccessful. The only positive fact resulting from the experiments is that the leaves and their preparations yield, under certain conditions, glucose.

Determinations have therefore been made of the amount of glucose yielded, as this is apparently an indirect measure of strength.

Thus I have found that the amount of glucose from the dried leaves is only about half that from the fresh; that the stalks of the leaves yield about five-sixths the amount obtained from the leaves freed from stalks; that the roots yield practically no glucose; that the juice prepared by expression of the leaves yields as much glucose as the leaves themselves; that a fresh infusion contains nine-tenths of the glucose that can be obtained from the leaves; and that the leaves can be exhausted by continuous percolation with dilute ethylic alcohol solutions, but that it takes a very large volume of the menstruum to exhaust a comparatively small quantity of leaves.

The following experiments seem to show that the yield of glucose from the leaves varies at different times of the year, within only narrow limits :—

November, 1905.—100 parts by weight of the leaves yielded glucose 5 parts by weight.

November 16th, 1905.—100 parts by weight of the leaves yielded glucose 4.7 parts by weight.

November 27th, 1905.—100 parts by weight of the leaves yielded glucose 4.1 parts by weight.

December 6th, 1905.—100 parts by weight of the leaves yielded glucose 4.8 parts by weight.

April 20th, 1906.—100 parts by weight of the leaves yielded glucose 5 parts by weight.

June 7th, 1906.—100 parts by weight of the leaves yielded glucose 4.7 parts by weight.

Although the results of the work on the chemistry of the leaves are inconclusive and unsatisfactory, a number of physicians have found preparations of violet leaves to be active.

The best form in which to present the drug is in a fresh infusion, the only objections to which are the large dose necessary to be taken, and the difficulty of getting a supply of fresh leaves all the year round. Failing this, a solution may be prepared by exhaustion with alcohol, and subsequent removal of the greater part of the spirit.

I described the method of making such a preparation fully in my former paper.

Some objection has been taken to the amount of alcohol in it, but up to the present I have been unable to substitute any other preservative which is satisfactory.

(*a*) Read before the Therapeutical Society on October 30th, 1906.

NOTES ON A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER. (*a*)

BY F. H. EDGEWORTH, M.B.CANTAB., D.Sc. LOND.

Professor of Medicine, University College, Bristol; Physician to the Bristol Royal Infirmary.

ACUTE yellow atrophy of the liver is such a rare disease that individual cases are worthy of publication. The following is the only instance which has occurred at the Royal Infirmary in the last eighteen years.

A woman, æt. 40, attended the out patient department on July 8th last, complaining of nausea, anorexia, and occasional vomiting for the preceding week. She had never had any serious illness, and had never been jaundiced before. She had drunk a fair quantity of beer. She was found to be slightly jaundiced, with a normal temperature, a good pulse of 90 per minute, no arterio-sclerotic changes, normal heart and lungs. The vertical extent of hepatic dulness was normal, reaching to the costal margin in the right nipple line. Nothing wrong was detected on palpation of the abdomen—no tumour or distended gall-bladder, or enlarged spleen. A diagnosis of catarrhal jaundice was made. Salicylates and saline purgatives were ordered.

On July 14th, one week later, she again attended. The nausea and anorexia were better, but the jaundice still persisted. The urine contained bile pigments but no albumen.

On July 20th, she felt sick again, had pain in the abdomen, and vomited repeatedly; on the following morning she gradually became comatose, and was admitted to the Infirmary about 11 a.m. I saw her at 12 o'clock. She was in a semi-comatose state, with clenched teeth, equal pupils slightly reacting to light, and moving a little when the skin was sharply pinched. The skin of a faint orange colour, was sweating profusely,

(*a*) Read at a meeting of the Bristol Medico-Chirurgical Society, January, 1906.

and the temperature was 99° F. The pulse was regular, of low tension, 134 per minute. The apex of the heart was ¼ in. internal to the left nipple line, and no added sounds were present. The lungs were clear down to the bases. The abdomen was flaccid, no enlarged subcutaneous veins were visible. No ascites, or tumour, or other abnormality was discoverable. The spleen was not enlarged. The vertical extent of the hepatic dulness was 2½ in. in the nipple line, the lower edge being a finger's breadth above the costal margin. The urine—a catheter specimen—was bile-stained, acid in reaction, sp. gr. 1023, and contained a fair amount of albumen; it deposited numerous bile-stained granular casts, but no leucin or tyrosin crystals; it contained 2 per cent. of urea.

There was no œdema of the legs; these and the arms were equally and perfectly relaxed. The knee-jerks were equal and exaggerated. There were some doubtful purpuric spots on the arms and legs. The fundi of the eye were pale, with normal vessels, and the optic discs were of a primrose-yellow colour. The patient was given 5 grs. of calomel in a nasal feed. At 3.30 the same afternoon she had a convulsion; twitchings began in the face and spread all over the body. At 5.15 p.m. she had another, and at 7 o'clock a third, in which she died.

On reviewing these phenomena, it would appear that the patient had jaundice for a fortnight, preceded by some gastro-intestinal symptoms; then coma of sudden onset, followed by convulsions, and death within nine hours of its onset. With these symptoms it was found that the liver had slightly diminished in size and that albumen had appeared in the urine.

At the *post-mortem* examination it was found that the brain, heart, lungs, abdomen, and spleen were normal. The uterus was slightly increased in size; it contained no fœtus or evidence of pregnancy. The kidneys were a little enlarged; they peeled well, and presented no naked-eye abnormality. The liver was considerably reduced in size and weighed only 32 oz.=⅓rds of normal; it was very flaccid; the capsule, which could be peeled off, was loose and wrinkled; the substance of the liver was of a mottled yellow and red colour, and no normal hepatic tissue could be seen. The bile-ducts were patent and contained no gall-stones. No evidence of phosphorus was detected on distilling portions of the stomach and intestines and their contents in the dark. On microscopical examination it was found that the cardiac muscle-fibres showed some pigmentary degeneration—a change probably quite independent of the fatal disease. There was extensive granular degeneration of the cells lining the convoluted tubes of the kidneys and desquamation of the cells lining Bowman's capsules. This was the cause of the albuminuria and tube-casts in the urine.

In the areas of yellow atrophy in the liver the hepatic cells were granular and their nuclei were hardly visible. The epithelium lining the smaller bile-ducts was proliferating. Round the bile-ducts and vessels in the portal spaces there was some increase of fibrous tissue—due no doubt to the patient's alcoholic intemperance. In the areas of red atrophy the hepatic cells had altogether disappeared. The microscopical examination thus showed evidence of acute necrotic degeneration of the liver cells, with a small amount of cirrhosis. The same poison (? of bacterial origin) which destroyed some and damaged others of the hepatic cells also damaged the secreting cells of the kidneys.

The clinical manifestations of this case were almost, but not quite, typical of the condition. As usual, there was nothing to distinguish the first stage from ordinary catarrhal jaundice. The terminal stage was a little exceptional in that there were no signs of cerebral irritation—headache, restlessness, delirium—preceding the coma; the symptoms were abdominal pain and vomiting. No leucin and tyrosin were found in the urine; but it would seem that these substances are absent in about a third of published cases. The case, unfortunately, does not shed any light on the causation of this obscure disease. What the poison was, where it was produced, how it affected the brain, whether it accumulated in the body owing to its damaging the renal tissue, are all unknown.

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

Fracture of Both Patellæ at an Interval of Six Years.—Mr. Jackson Clarke operated on a woman, æt. 45, who had been admitted for fracture of the right patella. Five or six years previously she had broken the left patella, and had been treated in a London hospital, where the fragments were wired soon after the injury, but at the present time there was a slight interval between the fragments of the left patella, and the presence of this interval was explained by the patient as being due to the wire having been broken when the joint was first moved after the operation. In spite of this interval there was firm fibrous union, and the knee-joint was quite serviceable. The cause of the fracture was the same in both instances—the patient having tripped over some slight obstacle. The present fracture on the right side dated for some six months back, the patient's knee having "given way" suddenly and remained weak ever since, the woman being unable to walk; but she had no idea the bone was broken. She was pale, slightly built, and of middle height. The patient having been anæsthetised, a curved incision was made with its extremities at the sides of, and rather above, the patella, and its convexity crossing the front of the limb below the patella. The U-shaped flap was turned up, revealing the two fragments separated by a depressed interval of two inches. The broken surfaces of the bone were covered, the upper by a thin layer of aponeurotic tissue (the remains of that which had originally stretched over the front of the patella), and the lower by a layer of newly-formed cicatricial tissue over one-eighth of an inch in thickness. In clearing the fractured surfaces, the thin layer of aponeurotic tissue was removed from the upper fragment, whilst that covering the lower was dissected up from the deep towards the superficial surface, where it was left attached. The fractured surfaces of both fragments were then scraped until the cancellous bony tissue was exposed. The fragments were then perforated, each at two points, by a grooved perforator which greatly facilitated the passing of the wire. The wires were then tightened, and the flap attached to the lower fragment was used to cover the line of union of the two bones, which were next closely apposed. When the wires had been cut short the twisted portions were hammered down into this same fibrous flap. Stretch-

ing over the front of the joint, Mr. Jackson pointed out, was a thin sheath of slightly vascular cicatricial tissue, which quite shut off the joint cavity; this tissue was left undisturbed, since it prevented any blood or exudation from entering the joint. Nothing more remained but to close the wound, which was done by a few fine catgut stitches, the angles being left open for the insertion of two small tubes, which it was intended to leave in for twenty-four hours. Mr. Clarke said that the subject of wiring a fractured patella presented many points of interest. The first question was whether the operation gave results that were distinctly better than those of the non-operative treatment—*i.e.*, that by splints and bandages. He himself had no doubt that the results were distinctly better after careful wiring of the fragments because a firm union was obtained with a practically normal patella. This seldom resulted from the old treatment without operation. The second point to consider was the risks of the operation, and in this connection he strongly emphasised the importance of waiting for at least five days after the occurrence of the fracture before opening the joint; this interval allowed the damaged tissues to accommodate themselves to the presence of the blood and torn ligaments in the joint and between the fragments of bone, and after this interval, if the joint was opened with every precaution against sepsis, the risk of infection was extremely slight; but when it is remembered how awful the results of septic infection are in the knee-joint, it must be realised that no single precaution against sepsis must be relaxed. The incision Mr. Clarke had adopted in this case he said he preferred on account of its giving more complete access to the parts than does a lateral incision, and at the same time the skin incision was completely removed from the line of union of the bones. Mr. Clarke also remarked that the cicatricial flap that was used to cover the line of union between the fragments served the double purpose of making a bed for the twisted ends of the wires and of assisting nature in the formation of the new periosteum. The sheet of new tissue that closed the front of the joint, he pointed out, was in this particular case not attached to the patella, but stretched from the synovial tissue above and below its limits, hence it was not necessary to open the actual joint cavity. The dressing, he said, consisted of double cyanide gauze wrung out in 1 in 40 carbolic lotion, and this was covered by a small piece of jaconet to spread the exudation in the dressing and to prevent it coming through the bandages at one point as it often does when bones have been operated on and this precaution is omitted. The limb was put on a light malleable tin back splint, after the latter had been moulded by the hands to suit the contour of the patient's limb. The post-operative course in this case has been absolutely normal. The house surgeon Mr. Ferguson) having removed the tubes on the day after operation, the temperature remained normal. It is Mr. Clarke's intention to begin slight passive movements of the joint a fortnight from the date of the operation and to increase them gradually.

AN examination of candidates for not less than thirty commissions in the Royal Army Medical Corps will be held on January 24th and following days. Applications to compete should be made to the Secretary, War Office, not later than January 14th, on which date the list will be closed. Candidates who are over the regulated limit of age at the date of examination will be permitted to deduct from their actual age any period of service in the field after October 1st, 1899, that they could reckon towards retired pay and gratuity if such deduction will bring them within the age limit.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD OCTOBER 26TH, 1906.

The President, Mr. CLUTTON, in the chair.

MR. DOUGLAS DREW showed a case of

TRAUMATIC CEPHALHYDROCELE IN A FEMALE BABY ÆT. SIX WEEKS TREATED BY OPERATION.

The infant was admitted to the hospital within a few hours of the accident with a large swelling upon the right side of the head. There had been no loss of consciousness. For two days after admission twitching was noticed in the left arm and leg, and there was distinct impulse in the swelling when the child cried. The tumour gradually increased in size, and the gap in the bone became much wider—*i.e.* about half an inch. At the operation the sac containing the cerebro-spinal fluid was found to be formed of the separated periosteum. On allowing the fluid to escape profound shock ensued. The fracture was 1½ inches long, situated horizontally in the parietal, and measured half an inch across, and through the centre of the opening a hernia cerebri protruded. Owing to the condition of the child no attempt was made to suture the dura; both the bones were forcibly drawn together with silver wire, the hernia cerebri cut off, and the periosteum replaced and scalp wound sutured.

Mr. GODLEE commented on the rarity with which success followed operation in such cases, and congratulated Mr. Drew

Mr. CHARTERS J. SYMONDS showed

A CASE OF TRAUMATIC SEPARATION OF THE HEAD OF THE FEMUR.

Boy, æt. 16, fell from a tree early in 1904. Resumed work in three days. After six months had pain, and from that date has done very little work. The present condition showed shortening of the neck of the femur. Some limitation of movement. The skiagram showed that the head of the femur has been separated.

Mr. W. WATSON CHEYNE showed

MALUNITED FRACTURE OF BOTH BONES AT THE ANKLE JOINT.

Patient fell on July 25th, 1903, and twisted his left leg under him. The result was a bad fracture through base of internal malleolus and part of fibula at a higher level.

January 5th, 1904.—Admitted to King's College Hospital with very marked angular deformity, the leg being turned inwards just above the ankle, forming an angle of 150 degrees with the leg above it. The foot was also rotated inwards, and the patient walks on the outer border of the foot. Shortening of left leg.

January 13th, 1904.—Two lateral incisions made. Muscles and periosteum stripped off, and the bones which were fractured obliquely divided along the line of fracture. The fragments of the tibia were fixed together by an aluminium plate and tacks. The sharp end of the upper fragment of the fibula was inserted into the medullary cavity of the lower fragment, and thus the bones were kept in firm apposition without any wire.

Mr. T. H. KELLOCK showed a

CASE OF DEFORMITY OF THE LONG BONES.

The patient, a girl æt. 8. When aged three she was seen on account of slight genu valgum, and a few months after for greenstick fracture of the bones of the left forearm. About a year ago the left radius and ulna were again broken as the result of a fall from a chair. The deformity of the bones of the legs was now very great; there was very marked genu valgum, and the feet were strongly inverted as the result of curvature outwards at the lower ends of the tibiæ and fibulæ; the femora were a good deal curved in a forward and outward direction. In the upper limbs there was bending about the middle of the radius and ulna on both sides, although there was no history of fracture on the right side. At the upper ends of the humeri a

marked thickening and interior curvature was noticeable. Skiagrams of the bones showed that the chief part of the deformity is apparently due to fractures and irregular ossification occurring at short distances from the epiphyseal lines.

Dr. Garrod discussed the significance of the transverse lines seen above the epiphysis in the skiagram.

The President considered the affection to be one of rickets, although it was still progressing. He thought that many cases of fragilitas ossium were due to late rickets.

Mr. T. H. Kellock also showed a

CASE OF SYMMETRICAL AFFECTION OF THE HIP JOINTS.

Boy, æt. 8. The patient, when seven weeks old, had had a severe illness which was said to be dysentery, after which the right knee became very swollen and remained so for about two months, when it got quite well. He did not walk until eighteen months of age. About a year ago it had been first noticed that his gait was peculiar, but he had never complained of any pain in the hips and had not been laid up. Now he had a peculiar gait rather resembling that in congenital dislocations; the trochanters, especially the right, were raised, and appeared prominent when the legs were adducted. There was no pain nor tenderness, and the movements of the joints were free.

Mr. Warren Low compared the case to those of septic arthritis that occurred after adult dysentery, and which were often of long duration.

Mr. Percy Northcote and Mr. A. M. Gossage showed

A CASE OF PARTIAL HEART-BLOCK.

The patient, æt. 58. He had had syphilis at the age of twenty-one, but had otherwise been healthy until four years before, when he had a sudden attack of unconsciousness. Since then he has had numerous similar attacks. The attacks are either a momentary giddiness, or at other times complete unconsciousness for several seconds. On examination the arteries were found to be much thickened, the systolic blood-pressure being equal to 178 mm. of mercury. The urine generally contained a small quantity of albumen. When first seen the ventricles were beating at 68, but the patient suddenly felt slightly giddy, and the rate dropped to 32—*i.e.* to about the half of the former rate. As a rule the pulse-rate was 30. Observation under the X-rays showed that the auricles were beating at double the rate of the ventricles, and the bradycardia was probably due to depression of conductivity in the bundle of His between the auricles and ventricles. The more severe attacks were associated with the non-conduction of a series of auricular beats to the ventricle; for instance, in one attack no sound was heard over the heart for five seconds. In the tracing shown the interval between two successive ventricular beats was also about five seconds.

Dr. Alexander Morison discussed the sphygmogram in the case.

Mr. Gossage said that the intermediate sounds that were sometimes heard—they had not been heard in this case—were due either to extra systolic ventricular contractions or to auricular systole. They were very difficult to time.

Mr. Edred M. Corner showed

A CASE OF (?) SYPHILITIC DISEASE IN THE BONES OF ONE LIMB.

Girl, æt. 7, was noticed thirteen months ago to limp whilst walking. On August 2nd she came to St. Thomas's Hospital, when it was found that the right leg was 2½ inches shorter than the left. The upper section (from anterior superior spine of the ilium to lower end of femur): Right side, 9¾ inches; left side, 11¾ inches; difference 2 inches. The lower section (length of tibiæ): Right side, 7½ inches; left side, 8 inches; difference ½ inch. The shafts of the right femur and tibia were thickened, particularly at their upper and lower ends. The bones had an ill-defined surface, and in their internal structure presented a vacuolated appearance. The disease affects chiefly the epiphyseal ends of the shafts of these bones.

Dr. H. G. Turney showed

THREE CASES OF PATENT DUCTUS ARTERIOSUS WITH ARTERIO-VENOUS MURMUR.

The patients, who were all female, were of the age of 20, 29, and 31 respectively.

Dr. Charles Box suggested that the systolic part of the murmur might be due to ventricular contraction and the diastolic to arterial.

Dr. Ewart thought that two of the cases might possibly be due to pulmonary stenosis, the diastolic part of the continuous murmur being due to aortic regurgitation.

Dr. Frederick Taylor agreed with Dr. Ewart. Even when a patent ductus arteriosus was present, no continuous murmur might be heard.

Dr. Turney said that a continuous murmur occurred, apart from a patent ductus arteriosus, only with an aneurism leaking into a venous trunk or with an infective arteritis doing thus. Both these latter conditions could be excluded in this case.

Sir Hugh Beevor showed a case of

LARGE CYSTIC ABDOMINAL TUMOUR, PROBABLY OF RENAL ORIGIN.

Boy, æt. 16. Symptoms of mechanical interference only. Blood normal. Condition stationary for twelve months. Dyspnœa, first noticed two years ago.

Mr. R. J. Godlee showed a

CASE OF DOUBLE COXA VARA.

The patient was a boy, æt. 16, who stated that, though he always turned his toes out, he was active and could play games up to August, 1905, when a barrow fell against him and broke his right thigh. The right great trochanter was more prominent than the left, and was three-quarters of an inch above Nélaton's line. Both limbs were rotated out; abduction, flexion, and rotation in were much limited. Walking was difficult; the gait was that common in cases of coxa vara. Skiagrams showed double coxa vara, with possibly fracture of the neck of the right femur.

Mr. H. C. Semon (introduced by Dr. J. Rose Bradford) showed

A CASE OF XANTHOMA, WITH ENLARGEMENT OF THE LIVER.

The patient, a widow, æt. 60, was admitted to University College Hospital with the history that for seven years she had had jaundice. Two years ago numerous yellow masses developed on the limbs and body. The liver also was found to be enlarged, and laparotomy had been performed in the Sussex County Hospital. The organ was found to be indurated and scarred, and numerous enlarged glands were felt in the abdomen, along the spine, and in the portal fissure. At the present time the liver was much enlarged. The yellow nodules of the skin were in some cases movable, but in others appeared to be fixed in a varying degree to subjacent periosteum or bone.

Mr. H. C. Semon also showed

A CASE OF ACROMEGALY.

The patient, æt. 27, had suffered pain for three years in the left side of her face and cranium, occurring in paroxysms. The hands and feet had been gradually increasing in size during the last eight months. Besides the alteration of the hands and feet, the nose and tongue were enlarged. There was also well-marked bi-temporal hemianopsia, and both discs showed evidence of optic atrophy. Oblique illumination of the nasal half of the left disc produced only sluggish contraction of the left pupil. The urine showed a trace of albumin occasionally.

Mr. D. C. L. Fitzwilliams (for Mr. C. A. Ballance) showed

CHILD FROM WHOM A CEREBELLAR TUMOUR HAD BEEN REMOVED.

The patient, then æt. 4 years and 10 months, was admitted to the Hospital for Sick Children under the care of Dr. Colman in May, 1905, with symptoms of cerebellar tumour. An operation was performed by Mr. Ballance in June, 1905, and a large tumour (which was shown) was removed from the cerebellum. The child made a good recovery.

Dr. A. E. GARROD showed

A NEW CASE OF ALKAPTONURIA.

The patient was a girl, æt. 3. Her parents were not blood relations, and there were no other known cases in their families. The patient was an only child. Alkaptonuria was much rarer in females than in males, and only six or seven congenital cases in females had hitherto been recorded out of a total of about forty congenital cases. The child came under Dr. Still's observation as an out-patient on account of the appearance of her urine and the staining of clothing by the urine, which was noticed on the second day of life. The urine darkened on exposure to air, darkened conspicuously with alkalies, and yielded a transient blue colour with dilute ferric chloride solution. It reduced Fehling's solution with the aid of heat, and ammoniacal silver nitrate in the cold. It was optically inactive.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD AT 11, CHANDOS STREET, ON OCTOBER 19TH.

MR. W. MILNER BURGESS in the Chair.

DR. T. R. WHIPHAM showed a case of osteoarthritis in a girl, æt. 13, beginning last Christmas in both wrists and hands, and affecting later the knees and ankles. There was enlargement about the ends of the bones and swelling of the synovial membranes. The spleen was not enlarged, nor were the lymphatic glands, with the exception of a solitary gland in the left axilla. There was no family history of rheumatism or any joint affection in the family. The case was illustrated by skiagrams showing no obvious change in the bones or cartilages, the swellings being apparently in the synovial membranes and tissues around.

Dr. T. R. Whipham showed a girl, æt. 15, who was the subject of numerous deformities. The bones of the left side of the face were ill-developed, and there was deformity of the left pinna. The arch of the palate was high; the left shoulder was elevated; the arm shorter and with less muscular development than its fellow. Gaps could be felt in the second and fourth ribs. There were lateral curvatures of the spine in the cervical and upper dorsal regions. The left scapula was deformed and rotated inwards, and the muscles of the shoulder-girdle shortened, producing torticollis.

Dr. T. R. WHIPHAM showed a baby (female), æt. 10 months, with a congenital malformation of the heart. There was cyanosis and clubbing of the fingers and toes. The right side of the heart was enlarged, but no definite murmur was heard, though the first sound was a little soft. A striking feature was the great polycythæmia. In September the red cells numbered 12,900,000 per c.mm., with 150 per cent. of hæmoglobin, and the leucocytes totalled 12,000. This is the highest count that the author could find recorded in the literature.

Dr. WHIPHAM considered that probably atasia of the pulmonary artery was present.

MR. MILNER BURGESS showed two cases of hypospadias in brothers. In one child at birth there were three openings, one at the meatus and two in the penile urethra, and through the lowest opening a probe could be passed into the bladder. The second case was very similar. It was discussed whether the sexual function could be satisfactorily performed, and also when any operation should be performed, some writers favouring an early operation, and others deferring such proceeding till adult life.

MR. P. LOCKHART MUMMERY showed a child, æt. 7, somewhat lacking in intelligence, who since birth has been unable to supinate either forearm. The hands were in the position of pronation, and the amount of rotatory movement at the wrist is very small. An X-ray photograph was shown, and a discussion ensued as to its signification, whether the radius was normally developed or no, and, if the former, whether the condition was not due to spasm of the pronators secondary to a weakening of the supinators.

MR. H. S. CLOGG showed a case of bilateral congenital sinuses of the lower lip. The child was the fifth of the family, the other members showing no deformity. It was born with a severe degree of bilateral complete harelip and cleft palate. On the upper margin of the lower lip on either side of the mid line is a papilla, surrounded on the oral aspect by a groove. A sinus leads from this groove into the lip to just beneath the mucous membrane. The sinus is ¼ inch long. The two sinuses converge, but do not meet.

DR. ALEXANDER MORRISON showed a case of persistent arhythmia of the heart, a boy æt. 8. He had a neurotic history, and had had a severe attack of measles in 1904. There has been a persistent allorrhythmia, characterised by the occurrence at intervals of an extra systole and a long pause. At the moment of intermission there is a pulsation in the right internal jugular vein, and this wave coincides with the ventricular extra systole, as is seen in simultaneous tracings. There is no inconvenience to the child.

DR. L. GUTHRIE showed a case of anterior poliomyelitis of the fifth cervical segment of the cord, simulating Erb's type of paralysis. The boy, æt. 3½, showed atrophy and paralysis of the right deltoid, biceps, brachialis anterior and supinator longus The supra and infra spinati were only slightly affected. The supinator brevis escaped. The clavicular portion of the pectoralis major was wasted. Division of the fifth cervical nerve and grafting the distal end into the sixth nerve was suggested. The disease ensued on the opening of a small abscess in the right mastoid region when 13 months old.

MR. G. PERNET showed a case of multiple lupus vulgaris in a boy of 5. The disease had been present for two or three years. There were three foci of the disease, on the elbow and face.

DR. G. A. SUTHERLAND showed a boy, æt. 6, the subject of habit spasm. It began by movements of the face in December last year. These movements have continued and others developed. The movements consist in (1) blinking the eyes; (2) twisting the mouth; (3) jerking out the tongue; (4) jerking the head; (5) jerking the right shoulder; and (6) occasionally throwing out his legs and arms. In addition he makes curious laryngeal sounds at times. There is no history of rheumatism or chorea. He has been ordered glasses for hypermetropia. The condition has persisted 10 months, and shows no improvement.

DR. J. PORTER PARKINSON showed two cases of anæmia pseudoleukæmia infantum. The first case, a boy, æt. 20 months, had been treated since May by fresh air, iron, arsenic, etc., while the X-rays were applied three times weekly over the spleen. Great improvement resulted; the spleen diminished to a quarter of its original bulk, and the blood count, which had been markedly altered, became nearly normal. The general condition also had much improved

The second case was a child of the same age, and had been treated in an exactly similar way, the X-rays being omitted. In this child there was no improvement either in the general condition or the anæmia, nor did the spleen diminish in size.

MR. SYDNEY STEPHENSON showed a child, æt. 6½, showing a curious deformity of the eyelids. The palpebral fissure was directed downwards and outwards, exposing more of the eyeball than is customary. The eyelids could be closed voluntarily. There was no trace of the lower puncta lacrymalia. The lower part of the orbit was felt rough and unfinished owing to lack of parts of the malar bones and orbital processes of the superior maxillary bones. The only associated deformity was a diaphragm occluding the left external auditory meatus.

DR. C. O. HAWTHORNE showed a case of cerebral diplegia in a boy, æt. 5 years. The spastic condition was most marked in the right lower limb, but exaggerated knee-jerks and extensor responses were present on both sides. The left upper limb was approximately normal, and the right showed clumsiness of movement rather than spasticity. The boy did not talk, but

appeared to understand all that was said to him. The fundi of the eyes were normal, and the boy had never had any fits. He was a first-born child, born at full term with the use of instruments.

Dr. Hawthorne also showed a child having a coloboma of the iris, choroid and optic disc, and an infant with an extreme depression of the left half of the frontal bone, attributed to the use of forceps during delivery.

HARVEIAN SOCIETY.

Clinical Meeting held on Thursday, October 25th, 1906, at St. Mary's Hospital.

Dr. F. W. Clark, President, in the chair.

The following cases were shown:—

1. Dr. Sidney Phillips. (1) A case of Dextrocardia. (2) Congenital heart disease in a girl æt. 18. There was deep cyanosis present since birth, with marked clubbing of the fingers. No cardiac murmurs were present. He considered that the probable lesion was, absence of the inter-ventricular septum. Dr. John Broadbent and Dr. Maurice Squire discussed the case and agreed with Dr. Phillips as to the cause of the condition, and the latter related a recent post-mortem experience confirmatory of this.

2. Mr. Jackson Clarke showed three cases of congenital hip disease in children æt. 3, 3, and 3½ respectively, completely cured by operative treatment and exercises, and a fourth case in which the dislocation had been cured by operation; all that was now required was treatment by suitable exercises to relieve the abduction resulting from fixation in the abducted position.

3. Dr. Scanes Spicer showed a case of inoperable cancer of the throat, which had greatly benefited from injections of a vaccine of micrococcus neoformans.

Mr. Jackson Clarke, Mr. Spilsbury, Dr. Hill, Dr. Eastes and the President discussed the case.

Dr. Spicer then demonstrated a method of direct examination of the trachea and bronchi, or œsophagus, which was of great service in the removal of foreign bodies.

4. Mr. Parry Morgan, for Dr. Luff, showed a case of a large rounded tumour in the epigastric region of three months' duration in a man æt. 54, which appeared to be a carcinoma of the stomach. There had been sickness and pain, but now he was able to take food without discomfort.

Dr. Willcox stated that examination of the stomach contents showed the absence of free hydrochloric acid and the presence of a quantity of mucus, and considered that it was mainly the muscular coat of the stomach which was affected. Dr. John Broadbent thought that the growth might possibly be a sarcoma.

5. Dr. Willcox, for Dr. Luff, showed a case of copper poisoning in a man. The patient had had vomiting and abdominal pain, and when admitted there was a well-marked deep blue line on the gums and slight tremor of the hands. He had found copper and zinc in the urine and fæces. The patient had been doing a lot of brass polishing recently, and apparently must have been careless about cleaning his hands and been poisoned by brass, which is an alloy of copper and zinc. This appeared to be the only possible source of poisoning. Dr. Lamb and Dr. Eastes discussed the case.

6. Dr. Langmead, for Dr. Harris, showed (1) a case of pseudo-bulbar palsy. The patient was a man æt. 34, who eight weeks ago suddenly lost his voice and had some weakness of the right side and a coarse tremor of the right arm when excited. There was no obvious wasting of the tongue or paralysis of the soft palate, and he could swallow well. He could at times speak several words of intelligent speech in a whisper. Dr. John Broadbent considered that the case might be functional; the loss of voice was aphonia rather than aphasia, and came on suddenly; the tremor only appeared when the man was excited, and from the character of the symptoms it was difficult to trace them to any definite organic lesion.

(2) A case of tumour of the right optic thalamus in a man æt. 24. There was loss of power in the left arm and leg of five weeks' duration, blindness of the left lower quadrant, with headache, vomiting and optic neuritis.

Dr. John Broadbent showed a specimen of aneurysm of the aorta, which compressed the superior vena cava and had caused paralysis of the left vocal cord. The patient, a man æt. 49, who was to have been shown, had died suddenly five days before from rupture of the aneurysm.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held October 19th, 1906.

The President, Dr. Lindsay Steven, in the Chair.

The President referred to the great loss the Society had sustained by the death of Dr. James Finlayson.

Dr. J. Galbraith Connal showed several patients who had suffered from diseases of the nasal cavities and mastoid disease, of which we hope to publish particulars in our next.

Dr. Alex. McLennan gave an excellent demonstration of

Spirochætes from Syphilis, Yaws and Granuloma Pudendi,

and remarked that the probability of the spirochæta pallida being the cause of syphilis had been advanced somewhat by recent research. The serum from an eight months syphilitic had been found to possess at least a feeble agglutinating power over the spirochæta pallida, and also to still the movements of the living organism. Healthy serum does not do this. The organism has been found in congenital syphilis in numbers usually corresponding to the severity of the lesions. The further discovery of spirochætes on the skin of congenital syphilitics, apart from any local lesion, is important. Histologically the spirochæta pallida is found to inhabit the deeper structures rather than the immediate surface. It has also been demonstrated in countless numbers in sections of the congenital manifestations. These facts, while apparently supporting the view that the pallida is the cause of the disease, require some sifting. If this be so, then the view that the congenital type is only feebly contagious is unwarranted. Syphilis for its spread does not depend upon the congenital, but upon the surface discharges from the acquired lesions. In those the pallida is more evident in the deeper parts, and is admittedly scanty in the surface discharge. In the discharges from the primary and secondaries of the acquired disease numerous small protoplasmic bodies are found. They may be seen in some instances to have flagella, in others to be without. In a recent article in the *British Medical Journal* I have sought to show the relationship between these and the spirochæta pallida, which, while not being the cause of the contagion, may have something to do with its lesions, and is indeed part of the life cycle of the infecting organism. It is necessary to differentiate these organisms from artefacts, deposits of stain, and from protoplasmic buds from the tissue cells or from nuclear débris. Such buds I have found present in all smears from lymphatic glands enlarged from whatever cause. When, however, hordes of feebly staining bodies varying in size and shape are present in the surface discharge, the probability of their being protozoal becomes stronger.

The spirochæte found in yaws is, as already pointed out by Castellani, almost identical with the pallida, while those found in granuloma pudendi are more delicate, more closely waved, and very much longer and more difficult to stain.

The L.S.A. Diploma of the Society of Apothecaries was granted last week to the following candidates, entitling them to practise medicine, surgery, and midwifery:—C. F. W. Dunn, E. L. D. Gay, and G. M. Seagrove.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 28th, 1906.

CAUSES OF FACIAL NEURALGIA.

BERNHARDT defined facial neuralgias as "painful conditions seated in the sphere and territory of the sensitive branches of the tri-facial," which would mean that not only do the trunks of the branches and the nerve filaments suffer, but also the plexus of anastomosis with the facial nerve, and even the sensitive branches which ascend more or less the motor nerve. Consequently, it is natural to distinguish facial neuralgia properly so-called and neuralgia of the plexus of the face.

The frequency of neuralgia of the face is rather difficult to appreciate. According to Valleix, Eulenberg, Lachnit, neuralgia of the trigemini is the most frequent. Conrad and Bernhardt give the precedence to sciatica. Giurac thinks it less frequent than intercostal neuralgia and sciatica. The right and left side are about equally affected, and generally the pain is limited to one branch, although Valleix maintains that such is not the rule, that nearly always lancinating pains are felt in the two other branches of the trigemini.

Neither are authors agreed as to the sex. According to Chaponnière the two sexes are equally affected.

Cold, humidity. Sudden atmospheric changes play an undoubted rôle in the genesis of facial neuralgia and in the recurrence of the attacks. Certain *professions* predispose to facial neuralgia; it has been frequently observed in *cooks*. Emotions are frequently incriminated by the patients, and as a predisposing cause they cannot be denied.

In order to trace the true cause of facial neuralgia, two forms, says M. Levy, who has made a special study of the subject, must be distinguished: facial or minor neuralgia, and neuralgia of the gasserian ganglion, to which he gives the name of major neuralgia.

Minor neuralgia is so called from its simple and well-known causes, from its short duration, and its prompt yielding to appropriate treatment.

Major neuralgia is more obscure in its ætiology, appearing to depend on the temperament and the constitution of the patient. It is characterised by long duration, tenacity, frequent relapses, and its resistance to medical and surgical treatment. This variety is frequently found in persons of advanced life, and has a neuro-arthritic origin. Minor neuralgia invades frequently the first branch of the tri-facial, but can also affect the other two. The irritating agent which provokes it can have its seat on the whole course of the fifth pair.

The exciting cause may be found in the mouth, the nose, the eye, the ear, the face, etc.

Ancient authors were slow to admit the dental origin of neuralgia, but modern authors insist on the frequency of facial neuralgia due to lesions of the teeth. It can be the consequence of a physiological phenomenon, *eruption*. M. Ferrier observed several cases provoked by the piercing of the wisdom tooth, which is frequently accompanied with ulceration of the gum, or where the organ still enclosed in the maxillary bone tries to make its way out in the narrow space between the second molar and the ascending branch of the bone. In aged persons, the exaggeration of another physiological phenomenon produces the same results. The pulp, as is known, diminishes in volume in the aged, while the surrounding ivory develops considerably. It happens thus that in arthritic patients the pulp undergoes a process of calcification and compresses the nerves. Other dental causes are: caries of the teeth, periostitis, diseased roots and obturation of the caries without sufficient disinfection of the parts.

The nasal origin of facial neuralgia, a long time denied, is admitted to-day. Primary or secondary inflammations of the mucous membrane of the nasal cavities and of the sinuses provoke the malady, especially if the frontal sinuses are touched (supra-orbital neuralgia).

Superficial inflammations of the eyes (conjunctivitis, iritis, irido-choroiditis) can be accompanied by neuralgic pains. The same may be said of glaucoma.

Catarrh of the middle ear and its cavities is rarely a cause of neuralgia. But external lesions, eczema, suppurations have frequently been exciting causes.

Lesions of the trunks of the nerves are important factors of neuralgia. They are either intrinsic; traumatism with contusion of the nerve, compression by lymphatic ganglions, fibroma, cancer; or intrinsic: sclerosis of the arteries of the nerve, varicose condition of the veins, tumours, neuroma.

The trigemini may be irritated at the seat of Gasserian's ganglion, by exostosis, caries of the petrous portion, neo-formations of syphilitic or tuberculous origin compressing the ganglion and the roots of the tri-facial. Besides these exciting causes might be mentioned neuritis consecutive to certain acute infections (grippe, erysipelas, measles, typhoid fever, pneumonia), or chronic, of which the principal are: tuberculosis, syphilis, malaria. This latter is one of the best established causes of facial neuralgia.

If minor facial neuralgia is an accidental malady, it is not so with the major form, in which heredity plays an important rôle, and it can be said it is part of the pathological baggage of the neuro-arthritic family.

GERMANY.

Berlin, Oct. 28th, 1906

IN the Pathological Section of the Naturforscher-versammlung, Professor Baumgarten, of Tübingen, spoke on new experiments on the

PASSIVE IMMUNISATION FOR TUBERCULOSIS.

From his own observation on calves, passive immunisation was possible, but not under all conditions, and for this reason he had returned to active immunisation. In contrast to Behring, he considered subcutaneous injection advisable. He was able to set up tuberculosis of the lymph glands through the blood track, and from that he concluded the probability of the transmission of tuberculosis before birth.

Bartel (Vienna) found from his own experiments that tubercle bacilli settled within places where they found but few resistant cells.

Henke (Charlottenburg) in some cases found the starting-point of the disease to be the digestive track.

Dr. Westenhoffer (Berlin) spoke on the present state of our knowledge of

INFECTIOUS CEREBRO-SPINAL FEVER.

He said his investigations had culminated in the facts discovered that the cocci of the disease did not first of all infect the nasal mucous membrane, and from there reach the brain; but first of all the tonsils, and then the posterior wall of the fauces, from whence the invasion of the brain took place. It now remained to find out the carriers of the cocci.

Herr Jehl (Vienna) did not think that epidemics of the disease were sufficiently explained either by intermediary carriers or the conditions of dwelling-houses. It was not the common dwellings of the patients that was decisive, but common work-places. A thorough supervision of miners was an indispensable preliminary in the campaign against the disease. Workmen from infected mines should not be allowed to work elsewhere until it was ascertained that they were not carriers of cocci or that during the epidemic they had not stayed more than a day and night in the infected place. Transmission from child to child but rarely took place, as small children did not expectorate. In barrack epidemics immediate transmission from the diseased to the healthy could take place, as adults did expectorate. The reason why children were most frequently infected was that in them the tonsils were more largely developed. Children with very large tonsils were most frequently attacked. In the case of

adults dying of the disease, examination showed that they nearly all had especially large tonsils. Treatment up to the present had failed.

In the section for Hygiene, Professor Weber spoke on infection of the human subject by Perlsucht. There was a difference, in his opinion, between human and cattle tuberculosis, but cattle tuberculosis was transmitted as a food tuberculosis, and especially to children up to the 14th year. In Berlin he estimated that half the intestinal tuberculosis met with in children was due to cattle tuberculosis.

Frau Lydia Robinowitsch communicated the results of her recent experiments on tuberculosis, and concluded, as did Professor Weber, that cattle tuberculosis was communicable to man. She looked upon the occasional cause as the main factor for infection with this or that form of tubercle bacillus. Predilection on the part of the various excitors of tuberculosis for certain organs could be as little proved as a connection between the port of entrance or localisation to the tuberculous disease. Infection by food required the greatest consideration. Herr Zwick (Stuttgard) concluded that there was a separate cattle and human tuberculosis.

Professor Lehmann (Würzburg) spoke on the

Penetration of Industrial Material Poisons Through the Lungs and Skin.

Of the gases readily soluble in water, the workman takes in about 85 to 100 per cent. of the amount present. The admission into the system takes place altogether through the nose and mouth; scarcely any passed over the larynx, and that was when the gas was present only in small quantity. If the poisonous gases are carried direct into the lungs by a tube, the absorption is none the less, so that the deeper parts of the respiratory apparatus take up gases eagerly. In the case of carbon sulphide, about 22 per cent. is taken up. Poisonous gases are therefore to be excluded as much as possible. For many organic factory poisons, especially aniline and nitro-benzol derivatives, the uninjured human skin was specially absorbent. Cleanliness of the skin, the hair, the working clothes in work-places in which poisons are handled, should be looked after with the greatest care.

Dr. Brat was of opinion that the danger had become steadily less during recent years. Under ordinary conditions there were fewer accidents than formerly, and they were also of a slighter nature, but they were not excluded altogether. The buildings in which the businesses were carried on were more airy, and there were better arrangements for ventilation. Lehmann's view that poisons were absorbed to any extent through the skin was not in accord with experience, as the improvement obtained was entirely due to improvement in the atmosphere. In accidents happening, also, in the chemical industry, the diseases may almost always be traceable to breathing, although there was absorption through the skin. The question in actual practice was very different from what it was in the laboratory, and many laboratory experiments were misleading, such as that of the absorption of gases by breathing.

Professor Schottelius (Freiburg) spoke on preserved foods, and said that food that was recognised as bad should not be re-cooked or doctored by strong spices. Fresh food was better than all preserved food, so that the latter should be used as little as possible. German preserved foods were reliable. Some control over the age of the preserved food by the placing of some mark that need not be visible externally was desirable.

AUSTRIA.

Vienna, Oct. 28th, 1906

Chronic Influenza.

At the meeting for Internal Medicine, Kretz showed the lungs of a man æt. 56, who died after a very protracted illness. In 1900 the peritoneum began to fill with water, which was subsequently diagnosed as ascites following hepatic cirrhosis. This condition was followed by emphysema, ending in bronchiectasis.

The post-mortem confirmed the presumption of a bacterial origin, as the lungs, liver, and peritoneum were loaded with the germs. A thickening of the peritoneum and covering of the liver by the inflammatory process of the Influenza bacilli. The progress of the disease seems to have been slow, gradually creeping from the pleura to the peritoneum, where it lingered for years, extending back to 1900 for its origin, when the particularly severe influenza attack is recorded.

To confirm this hypothesis he recorded the history of several cases that occurred in 1897, which lingered for years and finally passed away with the same bacterial results. From these facts he endeavoured to establish this theory, that this chronic condition produced an immunity in the younger generation that made the recent epidemics impossible to occur in the future, as the resistance to infections would be higher, and thus destroy the pathogenic action of the bacilli.

Dilation of the Œsophagus.

Vollbracht presented a female patient, æt. 53, with an enormous pouch in the side of the œsophagus, caused by a stenosis at the cardiac end of the stomach. Nineteen years ago she was attacked with a severe febrile condition affecting the stomach and bowels, which lingered for some time. Nine months later she experienced difficulty in swallowing, which was found to be due to a narrowing at the cardiac end of the stomach. With the insertion of bougies and hydrotherapeutics she seemed to improve, and finally was passed off as cured.

In 1905 she was ill again, with increased difficulty in deglutition. The stenosis was found by measurement, 42 centimeters from the gums, and with difficulty a No. 16 bougie could be passed through the narrowing opening into the stomach. Above the stenosis the 16½ inches had a capacity of 450 cubic centimetres, or 16 ozs. In the stomach there was also an hourglass contraction, which increased the difficulty, but after a little manœuvring the sound could be got forward. By taking long inspirations and expirations, Valsalva's symptom was produced—viz., a cessation of the radial and carotid pulse while the intrathoracic pressure was increased. When manœuvring, air was pumped into the œsophagus with the glottis closed, which relieved the resistance of the cardia, when the contents of the œsophagus passed into the stomach with a rushing noise.

No real morbid condition could be assigned for the origin of this troublesome stenosis beyond a cardial spasm of the œsophagus producing the dilation above.

Glas said he preferred the œsophagoscope for such cases, as the details of the ecstasia could be observed and the extent of the dilatation exactly measured; the presence of tumours, ulceration, or other cicatricial tissue, as well as the interior walls of the dilatations are all brought into view. In addition to this, he applied the rays as a routine matter of confirmation.

Schwanz related a case of a purely nervous origin arising in the cardiac portion of the œsophagus, which produced a large spindle-shaped dilatation. Its first appearance dated as far back as 30 years, which was ushered in by severe dysphagia, vomiting and extreme inanition. The Röntgen rays revealed the psychic influence. In company she was unable to get anything into the stomach, but in private she could with great pain. The most notable feature in this case was when she was taken to the seaside, after long courses of treatment, she instantly recovered and could eat heartily at every meal.

HUNGARY.

Budapest, Oct. 28th, 1906.

At the recent meeting of the Nagyvarad Medical and Pharmaceutical Society, Dr. Adolf Erdös read a paper on

Urotropin and Helmitol.

The properties of urotropin as uric acid solvent and urinary antiseptic are almost solely due to small amounts of formalin, which are split up both in acid and alkaline solution. It is therefore invaluable in acute and chronic cystitis, pyelonephritis, pyelitis, and posterior urethritis, and typhoid infection of the

bladder, to prevent nephritis in scarlet fever. After the use of instruments and in phosphaturia. The urine of patients who have taken urotropin will become ammoniacal less readily if kept than normal urine.

A comparatively new compound is the methylene citric acid salt known as "Helmitol." It is said to be superior, since decomposition occurs less readily, and the acid radical itself is a derivative of formalin. According to Dr. Erdös, helmitol does not, however, possess any therapeutic advantages, inasmuch as cases that do not yield to urotropin are not much benefited by this derivative. It is also more expensive, as larger doses are required, and the acid radical occasionally shows toxic propensities such as gastro-intestinal disturbance and eczema. The bromine water and Toressen tests for formalin in the urine are equally marked after corresponding doses of the two drugs, and the urine after the use of helmitol does not inhibit the development of bacteria any longer than with urotropin. Since helmitol is twice as expensive as urotropin, the latter should be given in all cases.

SYPHILIS IN THE APES.

Dr. Lazar reported an account of the successful inoculation of a chimpanzee with syphilitic virus from human sources. He stated that he also succeeded in inoculating a second chimpanzee with virus obtained from the first. The resulting eruption took the form of a generalised papular syphilide, and was well shown in a number of photographs which he had taken. The animal died shortly after with acute miliary tuberculosis, and the diagnosis could be verified by microscopical examination of the papules. He claims that this investigation demonstrates conclusively that infection of the higher apes with syphilis is possible, and that this animal may serve as a test object, as it were, for the virus and perhaps permit of the production of a specific serum.

PURIFICATION OF WATER WITH COPPER SULPHATE.

The Director of the Water Works of the City of Budapest made the statement that the water as it will be supplied to the city after completion of filtration plant will be absolutely pure, and will not need the addition of copper sulphate to render it free from typhoid bacilli. He said that the Department of Public Health, in doing what it had toward the use of copper sulphate, was striving for the purification of the water now being served. He is a firm believer in filtrated water, but does not advocate sitting quietly by and letting the scourge of typhoid continue, while the filters are being completed. The experiments in the laboratory are for the benefit of Budapest's inhabitants, until they are served with pure filtered water. Most of the speakers agreed that the use of copper sulphate in far greater quantities than are recommended for purifying the water would be harmless to the general population.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH UNIVERSITY GENERAL COUNCIL: PROPOSED AUTONOMY.—The business of the statutory half-yearly meeting of the General Council, held on the 26th inst., was of more than ordinary interest and importance. One of the disadvantages under which the Scottish universities lie is that none of them is completely autonomous. That is to say, that through the operations of successive university commissions, such a petty alteration as the inclusion of a fresh subject in a curriculum or the reduction of the number of lectures in a course can only be effected by a new ordinance. The ponderous procedure enjoined by the Act of 1889 involves the preparation by the university court of a draft ordinance, its submission to the General Council and Senatus for opinion, the promulgation of the ordinance to the other university courts, who may within two months lodge objections with the Privy Council, a report from the Universities Committee of the Privy Council, and the lying before Parliament for twelve weeks of session before Royal approval can be given. It is no wonder that such circumlocution leads to intolerable delay; a year may be spent in passing an unopposed ordinance, and four years have passed in the as yet unsuccessful attempt to get an unopposed one through. The crux of the question is whether each university is to be free to go its own way, or whether, as in the past, they must all toe the same line, neither advancing without the consent of her fellows. The arguments in favour of this uniformity are that the universities would start underselling each other, and that Edinburgh and Glasgow, being the more powerful, would outrun Aberdeen and St. Andrews if left to choose their own pace. It seems hardly necessary to do more than state such arguments in this bald manner to refute them. They only suggest the reflection that to offer them seriously involves the assumption that the community exists for the benefit of the universities, not the reverse. The Business Committee of the General Council, having received notice of the University Court's sympathy with the movement towards autonomy, have drawn up a report which was submitted to Friday's meeting. Their proposal is to create for each university a legislative council, to alter and make ordinances in all matters at present regulated by ordinance, and in regard to all other matters not already fixed by Act of Parliament. The Legislative Council for Edinburgh might (it is suggested) consist of fifty members, made up of the Chancellor and representatives appointed by the Court, General Council, Senatus, Lecturers and Assistants, Students' Representative Council, Crown, Town Council, other universities, Royal Colleges, Royal Society, Royal Infirmary, School Board, Merchant Company, Heriot Trust, and Chamber of Commerce. The scheme as above outlined was adopted as a basis for discussion with the proviso that the Council did not stand committed to its details. It is premature to express any opinion on the liklihood of such autonomy being attained in the immediate future, and no doubt in many points careful consideration and criticism will be required. But of the broad principle that the universities should be self-governing, no one who desires reforms has any doubt, and a legislative council like the above certainly appears to represent nearly all the interests concerned in university work, and would bring the University into close touch with most of the other educational authorities in the city.

COMPULSORY NOTIFICATION OF CONSUMPTION.—At the last meeting of the Glasgow Town Council a minute of the Public Health Committee advocating the compulsory notification of pulmonary phthisis was passed unanimously.

PHYSICAL CONDITION OF THE CHILDREN OF EDINBURGH POOR.—A volume has just been issued by the Edinburgh Charity Organization Society reporting on the results of the examination of 1,400 school children in one of the poorest districts of the old town. The report is of great interest on account of the exhaustive nature of the investigation, for not only was the physical condition of the children examined by medical experts, but their home surroundings were inquired into by named visitors. We can only briefly mention a few of the points raised in the volume, which is well worth the attention of all interested in social reform and the health of the community. One feature of the statistics is the large percentage of cases in which the mothers were wage-earners—282 out of 781 families—and this was found to be closely connected with drinking on the part of the father. Only 29 of these working mothers were from sober, respectable homes. A fifth of the houses visited were "ticketed" according to the city regulations, as containing less than 2,000 cubic feet, the allowance being 400 feet for each adult. Overcrowding, however, was as common in the larger, "unticketed" houses as in these; in one case the space worked out at 143 cubic feet per inhabitant. Rather less than 20 per cent. lived in one-roomed houses, and

rather over 50 per cent. in two-roomed houses. Another 20 per cent. lived in three-roomed houses, and the rest in four and five-roomed houses. Turning to the details of more purely medical interest, 45 per cent. of boys, and 42 per cent. of girls, were of excellent or good mental capacity, and about 18 per cent. of boys and 20 per cent. of girls were classed as dull or defective As to general health appearance, 9.5 per cent. were bad, 45.7 were medium, and 44.8 were good. The nutrition was poor, nearly one-third being classed as thin, the largest number of these being between the ages of 6 and 9. As regards alertness in answering questions, 20 per cent. were given as bad, these being almost entirely drawn from children classed as poor in general health and nutrition. At all ages the weights of boys and girls compare unfavourably with the Anthropometric Committee's standard. The deficiency was least among the young children (about 2½ lbs. at 5 years) and progressed steadily with age, at 13 being about 11 lbs. The stature was also defective. Of 1,330 children whose eyes were examined, 10.44 per cent. suffered from some affection of the ocular apparatus; 12.87 per cent. were working under eye conditions which formed a barrier to progress; 42.49 per cent. suffered from nose or throat affection. Functional heart disease occurred in 38 cases. Nearly 70 per cent. had unhealthy skins. At all ages the chest capacity of children living in houses of one room was least, though the difference from the average was not great.

LETTERS TO THE EDITOR.

"DIRECT REPRESENTATION" ON THE GENERAL MEDICAL COUNCIL.

To the Editor of The Medical Press and Circular.

Sir,—No one who has adequate knowledge of the facts will dispute the statement in the last sentence of Mr. Rutherford Morison's letter published in your issue of the 24th inst. It is certain that, "without a new Medical Act passed on the lines adopted by the British Medical Association, the chief evils from which the profession now undoubtedly suffers cannot be satisfactorily dealt with." It is, however, equally certain that there hardly exists the remotest chance that the present Government will introduce or support such an Act, and it is more certain that no private member, unsupported by the Government, can carry such a measure through Parliament.

This opinion, supported by argument, I stated in the *British Medical Journal* a year or so ago, and I have repeatedly discussed the question in your columns. Before new legislation becomes possible, it will be necessary to prove that it is demanded more for the protection of the public than the advantage of the profession. This, as I have suggested, can be done in the most complete and convincing fashion through the medium of a Royal Commission, and in no other way. The infamy of quackery, including the quack medicine trade, could be there clearly and fully demonstrated. A hideous story of cynical villainy would be unfolded which could not fail to touch the consciences of the intelligent classes and of their representatives in Parliament. In the case of the lawyers it has been shown that practice by fraudulent pretenders can be easily prevented; and there could be no difficulty in constructing equally effectual legislation for the doctors. The greater part of the trade in quack medicines could be brought within the scope of ordinary criminal law. Most quack medicine vendors could be made liable to prosecution for obtaining money under false pretences, and could be placed under the surveillance of the police. It must be borne in mind that no help in this movement will be given by the lay Press. From the *Times* downwards they are all taking a share of the enormous sum—certainly more than a million sterling—which is being spent annually in advertisements by quacks. Exposure of the facts before a Royal Commission might bring shame to some of the wealthier newspaper proprietors, and we might hope that one or two of the noble lords who own leading papers, and who are now augmenting their incomes by participation in this nefarious traffic, would turn away and throw in their influence on the side of reform. They would, at any rate, no longer have the excuse of ignorance to justify their conduct.

I am, Sir, yours truly,

Henry Sewill.

Cavendish Square, October 25th, 1906.

To the Editor of The Medical Press and Circular

Ladies and Gentlemen,—In placing my services at the disposal of the profession in the ensuing election for Direct Representatives on the General Medical Council, I may be allowed to say that, in order to show that my efforts in the past have not been confined to a narrow groove, I have been for many years a member of the British Medical Association, and since the Cheltenham meeting a member of its Central Ethical Committee and its representative on the Contract Practice Sub-Committee in 1905-6, that I have attended all the representative meetings of the Association on behalf of the North Manchester Division; that I am a member of the Council of the Lancashire and Cheshire Branch; a vice and ex-President of the Incorporated Medical Practitioners' Association and have been a member of the Council of the Medical Guild practically since its foundation some 14 years ago and took an active part in its initiation. All this has given me considerable insight and experience as to the difficulties and trials as well as shortcomings of everyday practice which might prove useful in the General Council of Education and Registration in London.

I have recently expressed my views in the "British Medical" and other journals as to the necessity of lectures being given to senior students on ethics to supply the deficiency caused by abolishing the apprenticeship system, and of raising the standard of preliminary education, both in arts and science, before registration, which I need not repeat now.

I am also in favour of stringent action on the part of the Council in any proved cases of touting for vaccination on the part of the Poor-law Medical Officers or their agents, even in those employed by the guardians, and I would go so far as to consider whether proved cases of gross underselling should not be considered "infamous conduct in a professional respect," not only as an injustice to their fellow-practitioners but as lowering the dignity of the profession in the eyes of the public.

The craze now for registration that midwives have secured is certain to be attempted not only for nurses but spectacle-makers, herbalists, etc., and will require careful watching during the next five years, and the General Council will require keeping on the alert not only for the protection of the public, but if it were possible that of the profession as well, inasmuch as the President has stated that the Council's resources are not yet exhausted. Abolishing unqualified assistants not only benefited the public but the profession.

It has always been my endeavour, in season and out of season, to secure as far as possible the union and the interests of the profession, and especially by promoting new as well as old combinations of various kinds.

My personal experience of Provident Dispensaries, and another large provident association, when on the staff of which I fought for th honour and dignity of the profession in the face of strong opponents, and for many years since leaving them, for a wage limit, is well known in my immediate neighbourhood. All this practical experience, in addition to that gained as a general practitioner for upwards of a quarter of a century, would surely be of use in a Council composed mostly of professors and consultants who know nothing

of these matters personally, and would be of assistance in cross-examination of delinquents when brought before it.

If it is possible in a new Medical Act to protect the public from the barefaced assumption of medical titles, especially by companies, and from other means of deceiving it, I need not say that it will have my hearty support.

The experience gained during the three years I have sat on the Central Ethical Committee of the British Medical Association, not one meeting of which have I been absent from, ought to be of some service to me if elected to the General Medical Council.

The reckless distribution of medical services without any regard to wage limit to the injury of respectable qualified practitioners should surely be adjudged "infamous conduct in a professional respect" as in any other.

Believe me, Ladies and Gentlemen,
Yours faithfully,
G. H. BROADBENT,
M.R.C.S.Eng., L.R.C.P.I., L.M.

LAW FOR LAWYERS AND LAW FOR DOCTORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Times* of Monday, October 22nd, appears the report of another case illustrating the complete protection afforded to the legal profession and the public against the practice of unqualified men as solicitors. A debt-collector had used words to the effect that unless the money claimed were paid to his client, he would be obliged "to take the case to the High Court." He had adopted no title and used no expression beyond the one cited which could be distorted into an attempt to palm himelf off as a solicitor Yet the magistrate held that the words could properly be used only by a qualified man, and inflicted a fine of £10 and costs, with the alternative of imprisonment. When it is considered that the practice of medicine in its various branches by quacks inflicts upon the public vastly greater injury than could be brought about by any amount of unqualified practice in the law, it is impossible to believe that if the facts were fully exposed, legislation would not be speedily attempted to put an end to some of the evils due to the present weakness of the Medical Acts. When will the profession wake up to a sense of its duty in this matter to itself and to the public? When will it take steps to prove its case and demand the legislation so urgently called for?

I am, Sir, yours truly,
AN AWAKENED "G.P."

October 23rd, 1906.

M.D., U.S.A.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last issue you commented upon the case of the Brighton man who sold powders for various diseases under the name of "Dr. Hawkins, M.D., U.S.A." You ask why the General Medical Council should not be empowered to prosecute in such cases, and echo answers "Why?" If a man carries on unqualified practice in the United Kingdom under a bogus or an unrecognised medical qualification, he is clearly open to prosecution. Now only last week a man giving the name "Dr. Riley, of Hanover Square, London, and Datchett," appeared at an inquest on the body of a woman whom he had prayed over as a Christian Scientist at the rate of a guinea per week. He said, in defence, that he had held the degree of the University of Missouri, but was struck off the roll in 1897, when he joined the Scientists. It appears he still appends the letters M.D. to his name. Perhaps the secretary of the Medical Defence Union, Dr. Bateman, will kindly inform us as to the exact legal position in this case. It would be well if the Union also gave us full particulars as to the nature of the business carried on at Hanover Square. What is the exact address, and is it connected with electrical or any other form of special treatment.

I am, Sir, yours truly,
AN EXTINGUISHED PRACTITIONER.

West Kensington, October 30th, 1906.

THE SUPPRESSION OF QUACKERY.—DENTAL SURGEONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You are placing dental surgeons under an obligation by the consideration you are giving to their speciality in your efforts to promote medical law reform. In 1858 the Royal College of Surgeons obtained, through the new Medical Act, power to institute a diploma in dental surgery. It was, however, not until 1878 that dentistry received full recognition, and was placed under the control of the Medical Council. The Dentists' Act of 1878 was passed through Parliament without amendment. It was proved that the practice of dentistry could not be properly pursued save by educated professional men; it was sought to create a body of qualified practitioners equal to the demand, and to enable the public "to distinguish between qualified and unqualified practitioners." By giving dentistry a status as a profession the Act has attracted a large number of highly qualified men into the speciality. The Act has, like the Medical Acts, completely failed to afford these men any protection in return for the sacrifice called for in obtaining the State qualification; and it has failed equally in its object of protecting the public. There are more quack dentists now than ever. Some practice under the cloak of sham American "institutions"; others under the mask of limited liability companies. Quack dentists vary in badness, but many of them belong to the army of fraudulent pretenders denounced by the *Times* as "the most finished of impostors parasitic upon modern civilisation." Their victims are mostly simple and foolish women; the bait, artificial teeth of marvellous qualities, or teeth at a price which would not pay even if the job could be reduced to an operation as simple as the measuring for a pair of boots. The sham Americans catch the wealthier, the cheap tooth-purveyors take in the less wealthy classes. Both species of quack rob their victims, and misuse them. They both neglect the treatment of remaining diseased teeth and stumps, and leave the mouth in a septic state extremely prejudicial to the general health, as well as a frequent cause of serious local disease Not a single patient applying to the cheap dentist ever obtains a set of teeth at the price advertised; many times the price is mostly extorted for ill-made work, and many weak women of the kind easily recognised by a clever quack are virtually blackmailed. The quack's safety lies in the fact that no sensitive woman will go into the witness box to expose her folly. Any number of such cases will be brought forward if your project of a Royal Commission be realised.

I am, Sir, yours truly,
M.R.C.S., L.D.S.

DOCTORS' INCOMES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is not easy to say whether any good will come from the "remarkable contribution" offered in the columns of the *Daily Telegraph* "to a controversy which has excited the widest interest at home and abroad."

The views expressed in the article in the *Daily Telegraph* (October 22nd) would lead one to the conclusion that the prospects of the general practitioner are not likely to improve. It would seem that things have changed so much of late years in the practice of medicine that hospitals have become a necessity, and that they are no longer limited to the class they were originally intended to benefit. The *Daily Telegraph* makes no allusion to the great system of rate-supported institutions, such as fever hospitals, infirmaries, asylums, etc., which carry on the chief part of the work once done by hospitals. Much the same change has come about in the treatment of the sick as in that

of education, and the influence of charitable sentiment does not enter, as it used to do, into the financial question of ways and means. No reference is made by the *Daily Telegraph* to this question, or the financial difficulties in which most hospitals find themselves. Some day, perhaps, there will be a change in the methods of legal procedure in this country, and some provision be made for the gratuitous aid required by the poor when in legal difficulties. The law certainly receives very far greater help from the State than medicine does, and it would have been well if the *Daily Telegraph* had pointed out clearly that hospitals will have to be supported in a very different manner than they are now if they are to carry on the work expected of them.

As to the general practitioner, the *Daily Telegraph's* remarks are generous and just; but no hope is held out to him that his "bitter cry" will be heard with pity and some form of consolation by the great class to which the work of his life is devoted.

It would have been well if the *Daily Telegraph* had clearly distinguished between the work of hospitals and the work of the general practitioner; how impossible it is for hospitals to meet the necessity for medical care, and help in the common family life of all classes; and how the general practitioner is as necessary as the hospital in preserving the health and well-being of the people.

I am, Sir, yours truly,

Cantabrigiensis.

OBITUARY.

EDWARD DRUMMOND, M.D.Edin., D.P.H.

We regret to announce the death of Dr. Edward Drummond, a well-known writer on medical subjects, who has just died at St. Annes-on-Sea. Educated at Edinburgh University, he began private practice at Oldham, where he obtained several public appointments, but in 1876, owing to ill-health, he took to travelling. He was later appointed physician to the British Embassy and Scots College in Rome, and while there made special contributions to the study of malaria, and also wrote a confidential report for the late Queen Victoria on vivisection in Italy. Following his return to England Dr. Drummond was a keen student of bacteriology, and made several valuable contributions to medical literature.

WILLIAM SEDGWICK, M.R.C.S., L.S.A.

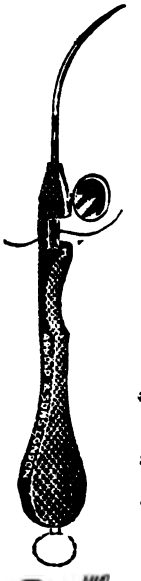
We record with sorrow the death of Mr. William Sedgwick, which occurred at Acton on October 20th. He had the interesting experience during his student days of acting as surgical dresser to Liston at University College Hospital, when the first operation in London was performed under an anæsthetic. After some voyages to India and China in charge of troops, Mr. Sedgwick settled in Marylebone as a general practitioner, but he also devoted a good deal of attention to the study of heredity, and published articles upon the subject. During the great cholera epidemic of 1854, Mr. Sedgwick devoted much attention to the chemical changes incidental to the disease, and made them, in 1889, the subject of his presidential address to the Harveian Society. He was for 13 years surgeon to the Marylebone Provident Dispensary and to St. Saviour's Hospital for Women and Children, Upper Holloway, and for upwards of 20 years honorary medical officer to St. Cyprian's Orphanage, Marylebone. He only retired from practice about two years ago.

WILLIAM BODKIN, M.D.R.U.I.

We regret to announce the death of Dr. William Bodkin, at the age of 63 years. For upwards of 40 years deceased was in practice at Chelmsford, where he was widely known, both in a public and in a professional capacity. His medical education was conducted at Queen's College, Belfast, whence he took the "M.D." degree in the Royal University of Ireland in 1867. He leaves a son, who recently qualified for the medical profession.

IMPROVEMENTS IN SURGICAL APPLIANCES.

NEW NEEDLE-HOLDER FOR POCKET-CASE.



Mr. Leslie Thain, M.R.C.S., Medical Officer to the Dore Union Workhouse, claims for this instrument that it will hold the usual bayonet needles of a pocket-case, and possesses the following essentials:—

Perfect grip of the needle by means of screw, tube, and rest-recess; funnel eye-finder—with it a needle can be threaded in the dark. It is roughened everywhere, and can be held anywhere, even with the forefinger nearly on the needle point.

By moving screw to the other end, it goes in a pocket-case, and is far more necessary than the combined Bellocq's and catheter. The method of use is: Move the screw to the needle channel. Hold the holder upright between left thumb and three fingers, back towards you. Drop needle into the tube till the eye end falls into the rest, and then, with left forefinger, press the concavity of the needle. The eye now corresponds to the eye-finder, and the needle can at once be threaded or after the next stop; now screw tight. Messrs. Arnold and Sons, London, are the makers.

IMPROVED VACCINATOR.

The same manufacturers have also made, at the suggestion of Mr. A. A. Mackeith, M.B., of Southampton, a vaccinator which he thinks embodies some slight improvements on those at present in use.

It combines in one instrument a lancet and a scarifier. The ends are kept clean by screw-on covers of distinctive sizes, so the instrument can be easily carried in the pocket or vaccinating case. The body or centre is square, which prevents the instrument rolling about, and is of such a size that the ends are prevented from touching the surface on which it is placed. The scarifier being bent at a considerable angle enables one to use the back of it to rub in the lymph. There is a small hole in each blade intended for use when breaking off the ends of the vaccine tube.

"SALODENT."

For Cleansing the Teeth and Mouth.

Salodent has been in use for many years, and has established its claims as a fragrant antiseptic for the mouth and teeth. We find that it contains aromatic antiseptics, such as salol, eugenol, pinol, &c., so combined in it that the whole cavity of the mouth, as well as the interstices of the teeth may be scientifically cleansed. "Salodent" may be used in two ways: as a mouth-wash and as a tooth-cleanser. From personal experience we can testify to the excellence of this preparation, which is well up to the standard of modern scientific preparations for the toilet of the mouth.

MEDICAL NEWS IN BRIEF.

A Partnership Dispute.

SOME singular facts about a doctor's partnership came to light in the Marylebone County Court on the 25th inst. Dr. H. L. Snow, late senior surgeon at the Brompton Cancer Hospital, sued Dr. S. W. Wilson, of Brondesbury, late Registrar of the Irish Medical Council, for £94 odd in respect of breach of a partnership agreement, etc.

According to Dr. Snow, premises situated in High Road, Kilburn, were opened by him in September of last year as a dispensary for women. In January of the following year he advertised and defendant entered into partnership. Both parties were to share the expenses of the undertaking. In July, Dr. Wilson met his partner, and told him that unless he could show that he had paid the last quarter's rent of the premises he should break the connection. Dr. Snow informed him that the account for the rent had not been presented, but, in spite of this, defendant failed to perform his duties that day, and on the following day, when plaintiff went to the surgery, he found that defendant had carried off bottles, instruments, drugs, and pills, so that it was impossible to attend to any patients had they applied for treatment.

Cross-examined, plaintiff admitted that he had advertised the business at price of fixtures, "on account of sudden illness of vendor." The last clause was put in because he had had three attacks of influenza, and was not meant to deceive, although he was able to attend to his duties when the advertisement was inserted. With regard to phrase, "no competition," plaintiff said he was not aware that there were fifty doctors within a radius of half a mile of the place.

"Were you not distributing advertising matter in connection with this dispensary from door to door shortly before you entered into negotiation with defendant?"—"Yes."

"Don't you know that the General Medical Council have struck doctors off the Register for advertising?"—"I do not."

"Did you not receive a letter from the Medical Defence Union, in which the writer said, 'I am directed to call your attention to what would appear to be some misuse of your name by some person impersonating you'?"—"Yes."

"And did you write back to say that some ill-advised person had been personating you, and that you would inquire into it and see that it was stopped?"—"Yes."

"So you were going to inquire into a distribution of circulars that you were paying the Church Army to distribute, and you told Dr. Bateman that somebody was impersonating you?"—"I thought the letter was offensive."

"Did you tell your partner of this advertising?"—"No, because it was stopped before he started with me."

For the defence it was submitted that plaintiff had confessed to using the money which defendant paid him for rent for household purposes, and that Dr. Wilson was so alarmed by the evident embarrassment in which his partner was that he felt justified in breaking the partnership.

Sir William Selfe said that he considered there was ample reason for the defendant's claim for a dissolution of partnership. Plaintiff's reply to the letter from the Medical Defence Union was disingenuous. The plaintiff would be indemnified for half the rent he might have to pay for the premises he had taken after he had proved that the money had been paid, but no order for costs would be made.

Royal Commission on Vivesection.

IN the House of Commons on the 25th inst., in answer to Mr. O'Grady (Leeds, E.), Mr. Gladstone said: I have received and considered a certain number of representations, but I do not propose to enlarge the Commmission, which is, in my opinion, fairly constituted as regards all parties interested. It is for the Commission to decide whether their proceedings should be public, and they have, I see, informed the Press this morning that they have decided to sit in private, but to supply copies of the evidence from time to time to certain representative bodies interested in the inquiry.—Mr. O'Grady asked whether it was not the fact that the majority of the Commissioners believed in vivisection.—Mr. Gladstone replied that out of ten Commissioners, four, including two distinguished medical men, were suggested to him by the Anti-Vivisection Society.—Mr. Lupton asked whether it was not the case that there were three vivisectionists on the Commission and no expert anti-vivisectionist at all. (Laughter.)—Mr. Gladstone replied that he did not know what his hon. friend meant by "expert anti-vivisectionist," but in the constitution of the Commission great care was taken to secure that all sides should be represented.

An Uncertificated Midwife.

ANN TROTT, of Totterdown, Bristol, was recently convicted under the Midwives Act, 1902, for using the name of midwife without being certificated, contrary to the provisions of the Act. Prior to the Act the woman had acted as a midwife, and should have registered herself as such, but she had not done so, and still kept up her plate on the house in Bath Road. The defendant said she had done this work for thirty years. P.C. Ryall said the defendant had been cautioned by the coroner and deputy-coroner and himself that she should take her plate down if she had no certificate. The defendant said her husband was blind and a cripple, and she had to maintain him. The plate was now taken down. The magistrates pointed out that the defendant must not go on practising unless she was registered, and she would be fined only 5s. and costs, as it was a first case.

Cost of an Epidemic.

IN 1905 Basingstoke was visited by an epidemic of typhoid, caused, it was believed, by the contamination of the water supplied from the corporation waterworks. That outbreak will cost the ratepayers upwards of £5,000 before it is done with. The hospital expenses and incidentals came to £2,500, for which the Local Government Board sanctioned a loan, repayable in five years, and this has just been taken up at £3 17s. 6d. per cent. There were no less than fifty actions brought against the corporation for compensation, and these were compromised at a cost of £1,670 15s., to which has to be added £600 to defend the actions up to the time of settlement. The Council have now decided to distribute £425 amongst 68 sufferers who did not bring actions. To meet these payments a supplemental rate of 1s. in the £ has been made. The repayment of the loan mentioned above will mean an addition of about 3d. to the rates each year.

Metropolitan Street Ambulance Association.

THE Metropolitan Street Ambulance Association, which was founded in 1904 to institute a working system of relief in cases of street accidents in London, has issued a manifesto to explain how it is that so little progress has been made. It appears that on August 3rd the Home Secretary said that he had the matter under his consideration, and the matter has thus

passed out of the realm of private or municipal enterprise and assumed a national character. Till, therefore, the Home Secretary is ready with a scheme, everybody else must mark time. The difficulties surrounding the question are great, not the least being the financial. But if the taxpayer is to come to the assistance of the scheme no doubt progress will rapidly be made.

Royal Commission on the Treatment of Lunatics.

The Royal Commission on the Care and Control of of the Feeble-minded have been entrusted with a new and important task. By an extension of their terms of reference, the additional duty has been imposed upon them of inquiring into the constitution, jurisdiction, and working of the Commission in Lunacy, and of other Lunacy authorities in England and Wales.

They will also investigate the expediency of amending the present system by the adoption of some other method of supervising the care of lunatics and mentally defective persons, and will report as to any amendments in the law as it now exists.

The Malthusian League.

A Conversazione will be held at South Place Institute, South Place, Finsbury, on Thursday, November 8th, at 7.30 p.m., when a short address on "The Rise and Progress of the Neo-Malthusian Movement," will be delivered by the President, C. R. Drysdale, M.D., M.R.C.P., F.R.C.S., followed by a discussion. Tea and coffee will be served, and instrumental music by members of Prince's Red Band will form part of the entertainment.

St. Vincent's Hospital, Dublin, Annual Dinner.

The annual dinner of the medical staff and past students of this institution was held on Tuesday, October 23rd, at the Shelbourne Hotel. The chair was occupied by Mr. Tobin, Surgeon to the Hospital, and a large number of distinguished guests were present. After dinner the toasts proposed included "The King," "St. Vincent's Hospital," proposed by the Chairman; "Our Guests," proposed by Mr. McArdle and responded to by the Archbishop of Tuam, Sir Christopher Nixon, Surgeon-General O'Farrell; "The Past Students," proposed by Dr. Cox; and "The Chairman."

PASS LIST.

Royal College of Physicians of London.

At the ordinary quarterly comitia of the College, held on Thursday last, the following gentlemen, having undergone the necessary examinations, were admitted to the membership:—C. H. Benham, M.D. Lond., L.R.C.P., Univ. Coll. Hosp.; W. Haig Brodie, M.D.Edin., F.R.C.S., St. Mary's and St. Barth.; P. Kevin Byrne, M.D.Lond., L.R.C.P., Univ. Coll.; E. Nicholson Cunliffe, M.D.Vict., Owens Coll.; H. Devine, M.B.Lond., L.R.C.P., King's Coll. and Bristol; J. McCrae, M.B., Toronto, L.R.C.P.; C. Oldfield, M.D.Lond., L.R.C.P., Leeds; A. Corsar Sturrock, M.D.Edin.

The Conjoint Board for England.

The following candidates having passed the Final Examination (in Medicine, Surgery, and Midwifery) of the Examining Board in England, the Licence of the Royal College of Physicians was conferred upon them on Thursday last. The names are arranged alphabetically:—E. H. Adams, E. Alban, E. Balthasar, A. L. Baly, M.A. Cantab; G. B. Bartlett, B.A. Cantab., H. G. Bennett; A. W. Berry; M. Birks, M.B., S.B., Adelaide Univ.; P. Black, B.A. Cantab.; H. O. Blanford; L. H. Bowkett; J. E. M. Boyd; G. G. Butler, B.A. Cantab.; W. E. Carswell, M.B., Ch.B., New Zealand; C. Cassidy, B.A. Cantab; J. B. Close; A. G. Cole; H. G. Cole; I. R. Cook; B.S. Lond.; J. Couper; S. B. Couper, B.A. Cantab.; P. P. Daser, M.D., Innsbruck Univ.; H. R. Davies; G. H. Dive; F. C. Doble; L. Doudney; S. F. Dudley; A. G. Dunn, M.B., B.S.,Durh. Univ.; L. Edwards; R. R. Elworthy; D. Embleton, B.A. Cantab.,; C. H. J. Fagan, B.A. Cantab; J. S. Farnfield, L.D.S.; C. H. Fernie;. P. Fiaschi, M.D. Columbia Univ.; R. D. Forbes, M.D., McGill Univ.; G. Foord, M.B., Toronto Univ.; W. Gabe; R. F. Gerrard; C. W. Gittens; G. E. Green; S. W. Grimwade; J. R. Gunne, M.D., B.Ch., Manitoba Univ.; E. H. R. Harries; T. S. Harrison; T. S. Hele, B.A. Cantab, B.Sc. Lond.; D. W. Hume; R. W. Ironside, B.A. Cantab.; T. j. Jenkins; D. M. Keith, Mich. Univ.; T. L. Kenion; W. R. Kilgour; W. H. King; C. Lebon, M.D., Strasburg Univ.; W. H. Lee, B.A. Oxon.; R. B. Low; J. A. McCollum, M.B., Toronto Univ.; O. R. McEwen; W. E. McLellan, M.B., Toronto Univ.; P. D. F. Magowan; E. S. Marshall; J. D. Marshall, M.B., Ch.B., Victoria Univ.; D. M. Masina, Bombay; E. W. Matthews; H. Maxwell; C. A. Mayer; F. E. W. Meadows; O. Le Fevre Milburn; S. W. Milner; H. V. Mitchell; W. S. Mitchell; E. Morgan; R. J. Mould, B.A. Cantab.; L. D. Neave; F. M. Neild; R. B. Nicholson; H. J. Nightingale; T. Norman; H. W. Ogle-Skan; M. W. B. Oliver, B.A. Cantab; G. G. Packe, B.A. Cantab; G. S. Parkinson; E. H. A. Pask; G. D. Perry; G. R. Phillips; A. J. S. Pinchin; A. M. Pollard; E. S. Prior; A. E. Pryse; R. M. Rendall; A. T. Rivers; P. M. Roberts, M.B., B.S. Lond; R. C. Roberts, B.Sc. Lond; I. J. Roche; T. R. St. Johnston, L.S.A.; C. N. Slaney; H. A. Smith, B.A. Cantab.; F. M. W. South; H. M. Staley; P. K. Steele, M.B., Ch.B. Vict.; A. C. H. Suhr, B.A. Cantab; D. W. Tacey, M.B. Cantab,; D. C. Taylor; O. Teichmann, B.A. Cantab.; H. E. H. Tracy, L.D.S.; C. Trapnell, E. A. Cantab.; W. H. Trethowan; C. Tylor, B.A. Cantab.; I. Valerio, Costa Rica; J. P. Walker, M.P.S., Leeds Univ.,; S. L. Walker, B.A. Cantab; C. G. Welch; C. E. Whitehead, B.A. Cantab; R. H. Williams; W. S. Williamson; H. D. H. Willis-bund; J. G. Willmore, McGill Univ.; J. L. Wood, B.A. Cantab; E. M. Woodman; H. N. Wright; A. B. Zorab; and C. E. Zundel.

Royal College of Physicians of Ireland.

At the stated annual meeting of the Royal College of Physicians of Ireland, the following officers were elected for the coming year:—

President, Dr. Joseph M. Redmond; Vice-President, Dr. Conolly Norman; Censors, Dr. Conolly Norman, Dr. Murphy, Dr. H. Jellett, and Dr. R. T. Smith. Additional Examiners to take the place of an absent Censor or Examiner—Medicine, Dr. J. A. Matson; Medical Jurisprudence and Hygiene, Dr. A. N. Montgomery; Midwifery, Dr. Glenn. Examiners for the Licence to practice Midwifery—Dr. Horne and Dr. Wilson. Examiners for the Membership—Dr. J. F. O'Carroll and Dr. Travers Smith. Clinical Medicine—Dr. Wallace Beatty and Dr. John Murphy. Practice of Medicine—Pathology, Dr. H. C. Earl and Dr. A. C. O'Sullivan. Supplemental Examiners under the Conjoint Examination Scheme—Biology, Dr. T. P. C. Kirkpatrick; Chemistry, Professor E. Lapper and Dr. N. Falkiner; Physics, Dr. G. J. Peacocke and Dr. W. A. Winter; Pharmacy, Materia Medica, and Therapeutics, Dr. H. C. Drury and Dr. M. Dempsey; Physiology, Dr. H. C. Earl; Pathology, Dr. E. J. M'Weeney; Medicine, Dr. A. R. Parsons and Dr. W. J. Thompson; Hygiene and Forensic Medicine, Dr. W. R. Dawson. Examiners for the Conjoint Diploma in Public Health—Chemistry, Professor E. Lapper; Hygiene, Dr. H. T. Bewley; Meteorology, Dr. W. A. Winter. Extern. Examiners for the Conjoint Preliminary Examination—Science, Mr. R. A. P. Rogers, F.T.C.D.; Languages, Mr. E. H. Alton, F.T.C.D.; Irish, the Rev. Professor Murphy, M.A. Representative on the General Medical Council, Sir John W. Moore. Representatives on the Committee of Management, Dr. Walter G. Smith, Sir John W. Moore, and Dr. Craig; Treasurer, Dr. H. T. Bewley; Registrar, Dr. James Craig; Librarian, Mr. R. G. Phelps; Architect, Mr. A. E. Murray, C.E.; Law Agents, Messrs. Stephen Gordon and Sons; Agent to manage the Trust Estate, Mr. C. U. Townshend, J.P.

During the proceedings the President admitted Dr. John F. W. Tatham, F.R.C.P.Lond., to the Honorary Fellowship.

In the evening the annual dinner of the President and Fellows took place in the College Hall.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Serum Treatment of Cerebro-Spiral Meningitis.—Flexne (*British Medical Journal*, October 20th, 1905) publishes an account of experiments in the serum treatment of cerebro-spinal meningitis. (1) He produced by inoculation of rabbits an anti-serum with marked protective power for guinea-pigs. The serum was injected in guinea-pigs (i.) 24 hours before the cocci were injected, (ii.) simultaneously with the injection of cocci, (iii.) some hours after the injection of cocci. The animals treated survived, whereas the control animals all died. (2) He produced by inoculation of large monkeys (*macacus nemestrinus*) an anti-serum with effect on smaller monkeys (*macacus rhesus*). Five monkeys were treated. The first received the serum (1 c.cm.) and the suspension of cocci (a lethal dose) simultaneously into the spinal canal; it remained well. Lumbar punctures showed a moderate reaction and rapid disappearance of the cocci, partly by phagocytosis, but also by lysis. The second monkey was given the serum two hours after the cocci; it became very sick, but recovered. The exudation in this animal was much more marked, and the cocci were only in part taken up by the leucocytes. The third monkey was injected with the serum five hours after the cocci were given. The disease, which had already shown itself, was arrested, and next day the animal was well. The fourth monkey was treated by subcutaneous injection two hours after the introduction of the cocci; it also recovered. The result in the case of the fifth monkey was a surprise. The injection of the serum had no effect on the progress of the disease, and the animal died. Control animals in every case died. The result of the experiments as a whole is very encouraging. It is shown that an anti-serum can be produced possessed of marked preventive and curative properties. It remains to be shown that some such serum can be applied to man, and that the introduction of an alien serum is not harmful.

R.

The Viability of the Typhoid Bacillus.—Wheeler (*Journal of Medical Research*, September, 1906) publishes a report of extensive experiments bearing on the viability of the typhoid bacillus. He concludes:—(1) The typhoid bacillus reproduces itself for several days in sterile water, particularly if there be any organic impurities present. (2) Diffused daylight acting through a thin layer of water is hostile to the growth of the organism. (3) The optimum temperature for the multiplication of typhoid bacilli in sterile water is 20-22° C. (4) Not all saprophytes are antagonistic to the typhoid bacillus. One, *B. carrotoverus*, manifests symbiotic relations with it. (5) Freezing reduces the number of typhoid bacilli in water, and typhoid bacilli do not live long in ice. The last of these conclusions is at variance with recent opinion, and as the point is one of much importance in cold countries, it will demand further study.

R.

The Organism of Hydrophobia.—Williams and Lowden (*Journal of Infectious Diseases*, May, 1906) review and summarise our knowledge regarding the so-called "Negri bodies" observed in hydrophobia. They have themselves worked by the smear method, and have demonstrated that examination of smears is quite as trustworthy as examination of sections, and is much more simple. According to them the Negri bodies are found before the beginning of visible symptoms, and are also found in fixed virus. In both these points the authors have made an advance on previous knowledge, the apparent absence of the bodies in the fixed virus having hitherto been considered an argument against regarding the bodies as causal in hydrophobia. Very small bodies have been observed which are probably capable of passing through the coarser Berkefeld filters. The authors believe that the bodies are protozoa with a definite morphological cycle, certain forms always predominating at certain stages of the disease. They further regard them as the specific cause of hydrophobia. Detailed instructions are given as to the methods of staining by Giemsa's solution and by eosin and methylene blue, both methods being simple and satisfactory.

R.

The Organism of Whooping-Cough.—Bordet and Gengou (*Annales de l'Institut Pasteur*, September 25th, 1906) describe an organism discovered by them in cases of whooping-cough. It was first described in 1900 as present in large quantities in the sputum, but at that time attempts at culture failed. It is an extremely small, ovoid bacillus, with a tendency to show polar staining. It fails to grow on ordinary media which have been subjected to sterilisation in the autoclave, but it grows readily in liquid media containing blood or blood serum. It is found in large quantities in the sputum in the initial stages of the disease. Moreover, the serum of patients suffering from or recently recovered from whooping-cough has a marked agglutinating action, whereas the serum of other subjects shows no such activity. The authors are now engaged in experiments regarding serotherapy and active immunisation.

R.

Spirochætes in Yaws and Granuloma Pudendi.—MacHennan (*British Medical Journal*, October 20th, 1906) notes that he has discovered spirochætes in smears from a papilloma in recurrent yaws. The method of staining was by Giemsa's solution and gentian violet, and the spirochætes observed possessed the same properties as the *spirochæte pallida*, but that the staining was fainter. Loops in the course of the filament were observed, as in the case of the *spirochæte pallida*. In the *granuloma pudendi*, on the other hand, no organism was seen at all resembling the *spirochæte pallida*. A few organisms resembling the *spirochæte refringens* were seen, and a number of highly refractive, very long spirochætes, with fine and close waving.

R.

The Typhoid Bacillus in the Lungs.—Robinson (*Bulletin of the Ayer Clinical Laboratory*, June, 1906) reports some instructive cases in which typhoid or similar bacilli were held responsible for lesions of the lung. In the first case the patient, at the end of the fourth week of a typical attack of typhoid fever, suddenly showed signs of infarction of the lung and died eight days later. At autopsy the main artery to the lower lobe of the right lung was found thrombosed, and the lobe was converted into an abscess cavity. There was also a general broncho-pneumonia. The typhoid bacillus was separated from the abscess and from other parts of the lung. This is the only case of six of broncho-pneumonia complicating typhoid fever examined at the Pennsylvania Hospital in which the typhoid bacillus was found in the lungs. In the second case the patient died on the eighth day of an illness presenting typical physical signs of pneumonia. He had bloody expectoration, and a low leucocyte count. At autopsy there was found a hæmorrhagic type of pneumonia, and from the lung tissue was obtained a pure culture of the B. paratyphoid bacillus. The third case was that of a man who developed pneumonia in the fourth week of an attack of typhoid fever. From his sputum and from his blood the typhoid bacillus was separated. Robinson gives copious references to

similar cases in the literature, and seems justified in concluding (1) that the typhoid bacillus not infrequently invades the lungs during typhoid fever; (2) it may there give rise to abscess and broncho-pneumonia; (3) lobar pneumonia, occurring in typhoid fever, is usually due to the pneumococcus, but it may be caused by the typhoid and the paratyphoid bacillus, and is then hæmorrhagic in type; (4) the typhoid bacillus may be found in the sputum of typhoid patients with pulmonary complications. This last fact should be emphasised in order that spread of the disease by this means may be prevented. R.

Multiple Malignant Tumours and Echinococcus Cysts in a Cirrhotic Liver.—Necker reports the case (*Zeitschrift für Heilk.*, 1905—XXVI.) of a man, aged 59, who was admitted to hospital suffering from abdominal pain. He was anasarcous, and presented all the symptoms of ascites. By aspiration 6 litres of fluid were removed from the abdominal cavity, but coma rapidly set in, and the patient died the next day. At the necropsy more fluid was found in the abdomen; both lungs showed pneumonic consolidation in patches. In the diaphragm there was an elastic tumour, the size of a nut, which on section was found to be white and of firm consistence. Similar tumours were found in the stomach, mesentery, omentum, and intestine. A tumour about the size of a goose-egg was also found in the under part of the right kidney. The liver was firm and irregular on the surface. Close to the diaphragmatic tumour a lump was seen in the liver about the size of an apple, and white in colour; beside this there was a yellowish tumour of different appearance, and near the gall-bladder there was a cystic tumour. On section numerous greyish-white nodules were seen, and many bands of connective tissue. The liver tumours turned out to be: (1) echinococcus cysts; (2) primary adeno-carcinoma of the liver cells; (3) sarcomata. The sarcomata were regarded as secondary to the tumour of the kidney, and were identical in appearance with the tumours in the stomach and mesentery, while the carcinomatous nodules were thought to have arisen from an attempt at compensatory hypertrophy of the liver cells, such as is often seen in cases of cirrhosis. Multiple malignant tumours of different histological appearance recurring in the same organ are very rare, and the author has only been able to collect 29 cases in all from the literature. M.

Multiple Cavernous Hæmangiomata of the Intestine.—MacCallum describes a specimen (*Johns Hopkins Hospital Bulletin*, August, 1906) illustrating the above indicated condition, and gives a summary of the literature bearing on the subject. The specimen was obtained from a patient who had been a constant drinker, and who died of broncho-pneumonia. Chronic pancreatitis, early cirrhosis of the liver, and general arterio-sclerosis were also found at the post-mortem. Throughout the small intestine one could see and feel small, firm areas, blackish-purple in colour, situated along the course of the veins, and reaching a diameter of from 7 to 8 millimetres. On cutting into them and squeezing out the blood, a spongy tissue was left, while microscopical examination showed them to be composed of a sort of cavernous tissue, the spaces of which were lined by endothelium. The veins in the neighbourhood of the nodules were both large and numerous. Apparently only one other case of this nature has been recorded, and that quite lately, but occasionally single cavernous angiomata, reaching the size of an almond and larger, have been noted, and have been the cause of intestinal and gastric hæmorrhage. In the other case resembling MacCallum's, and described by Benecke, the nodules were not limited to the small intestine, but were also present in the stomach and œsophagus. M.

Periarteritis Nodosa.—Under this heading Versé describes (*Münch. Med. Woch.*, 1905, No. 38) a patient who was admitted to hospital with dyspnœa, cyanosis, and general œdema. The temporal artery was much curved, and was very full; lungs normal; heart enlarged; pulse hard, irregular, and of high tension; slight albuminuria. Four weeks after admission the patient died, the clinical diagnosis being chronic nephritis, cirrhosis of liver, and peritonitis. At the autopsy most of this was confirmed. The peritonitis had arisen from two large perforations of the ileum. The small arteries of the mesentery were thrombosed and formed solid bluish-black cords. They were covered over with small nodular swellings of a similar colour, and about the size of peas. These on section turned out to be thrombosed aneurismal dilatations. The general thrombosis had caused necrosis of the intestinal wall and ulceration. Similar dilatations were found in the vessels of the colon, stomach, liver and spermatic cord and heart, the changes in the coronary arteries being probably accountable for some of the symptoms. Altogether about 20 cases of this nature are on record. The process develops as follows:—In the adventitia and outer part of the media of the arteries an inflammatory exudate occurs; this is gradually replaced by granulation tissue, which in contracting destroys some of the muscle of the media, and the process ultimately extends to and involves the internal elastic lamina. The vessel, thereby weakened, yields before the blood pressure, and numerous aneurisms result, the wall of each being mainly composed of cells, fibrin, and connective tissue, with remnants of muscular and elastic fibres. The etiology is unknown, but probably the most important cause is really syphilis. M.

The Physical Relations of Sugar in the Blood.—Asher and Rosenfeld (*Central für Phys.*, 1905, No. 14, S. 449) have investigated this question in order to decide whether sugar exists in a combined or in a free state in the blood. They have found that in all cases sugar is capable of dialysing out of sugar-containing blood, and of behaving, as far as dialysis is concerned, in exactly the same way as ordinary sugar solutions. Their results did not in any way suggest that it was combined with other substances, but showed that it existed in such a physico-chemical state as to still retain its property of diffusibility. The question therefore arises why sugar does not normally appear in various secretions, and the answer to this lies, according to the authors, not in physical, but in vital phenomena. They believe, in short, that the urine does not normally contain more than appreciable quantities of sugar, because the renal cells are capable of restraining actively its passage. M.

Growth of Lymphatics in Granulation Tissue.—This subject has been studied by Coffin (*Johns Hopkins Hospital Bulletin*, August, 1906). He points out that, while the development of lymphatics in the embryo has been fairly well worked out, practically no work has been done on the growth of these channels in the regeneration of connective tissue in the adult. Owing to the ease with which the intestinal lymphatics can be injected through the subserous tissue, granulation tissue was made to grow on the intestinal peritoneum in animals by drawing out a loop of intestine and sewing it to the wound in the skin. After about a week the loop was usually well covered with granulation tissue, and the animal was then killed and the injection performed. In this way it was shown that new lymphatic channels spring from those present in the tissue, and advance into the neighbouring new-formed tissue. The lymphatic sprouts resemble closely sprouting blood-vessels, and beyond the lumen of the channels the endothelial cells are continued in a single or partly double row for a short way. The channels are perfectly sharply outlined, and are completely formed of endothelial cells, standing in no more intimate relationship with the crevices of the connective tissue than do the blood capillaries. M.

We are not greatly impressed with the new monthly publication, *The Prescriber*, the first number of which is before us. It consists of four pages of matter, and we regret being unable to sum up its merits as *multum in parvo*—in fact, the multum is conspicuous by its absence.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CHANGE OF OUR OFFICE ADDRESS IN DUBLIN.

The Dublin Office of this Journal has been removed within the past week from 16 Lincoln Place to 18 Nassau Street. The latter premises are larger and more suitable, and will be open from ten to six daily, and on Saturdays from ten to two. Subscribers to the Journal and others desiring information regarding vacancies, *iccum tenentes*, and medical matters in Ireland generally, can always obtain it by applying to the Manager either by letter or personally.

BIOLOGIST.—The origin of the acoustico-facialis ganglion has not so far as we can trace, been made out in mammals.

DR. S.—In 1903, 628 patients were treated at the Pasteur Institute for rabies, with two deaths, and in 1904, 755, with three deaths. We cannot find any later official returns.

R. S.—The saying that "gout is to the arteries what rheumatism is to the heart," we believe is an adaptation of a phrase used by a French physician.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

ERRATUM.—The presidental address on "The Diagnosis of some forms of Dyspepsia," which appeared in our last issue was delivered before the Glasgow Eastern Medical Society by Dr. Thos. C. Barras, not by Dr. Wm. C. Barras as erroneously printed.

WELSHMAN.—The National Anti-vivisection Society was founded in 1875; the British Union for Abolition in (about) 1898.

MOTOR-CARS OF MEDICAL MEN.

THERE appears to be a little confusion in the minds of some owners of motors, judging by enquiries that reach us. Under the existing Motor-car Act, which has been temporarily prolonged, the owners of motor-cars are called upon to pay (1) for a licence to drive, (2) a registration fee, (3) a carriage tax of £2 2s. for cars under one ton weight, and of £4 4s. for cars over one ton in weight. It is probable in the near future these fees will be increased, unless some relief is granted specially to medical men.

Mr. C. H. S. (Brighton).—The demand on our space is so great at present that we are unable to insert further correspondence on the subject.

D.S.S.—The subject is scarcely within our province, but we will look into it.

CONSULTANT.—It would be better not to see the patient again without a distinct understanding. If he comes unasked there would be no reason why he should not be seen, on the understanding that his own attendant is written to.

L. T. P.—Claude Bernard was born 1813 and died in 1878. His first paper on vaso-moter nerves was read before the Société de Biologie in 1851.

THETA.—A paper on Ortho-Diagraphy appeared in the June number of *Medical Electrology and Radiology*. It is by Dr. Paul Kranse.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 31st.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5.30 p.m.: General Meeting to Discuss the Report of the Delegates concerning the Proposed Amalgamation of Medical Societies. 6 p.m.: Ordinary Meeting. Address:—Mr. H. Shirley-Jones (Droitwich) (President): The Art of Medicine in Ancient Egypt.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. Paton: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. G. A. Sutherland: The Treatment of Rickets.

THURSDAY, NOVEMBER 1st.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street).—9 p.m.: Address:—Sir Thomas Barlow, Bart.:—Remarks on Some of the Nervous Complications of Specific Fevers.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. C. O. Hawthorne: The Field of Vision in Health and Disease.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. G. Bankin: Medicine. 3.15 p.m.: Sir W. Bennett: Surgery. 4 p.m.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Seborrhœa and Psoriasis dealt with as Stages of the same Dermatitis in Symptoms, Diagnosis, and Treatment.

FRIDAY, NOVEMBER 2nd.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m.: Paper:—Dr. A. E. Giles: Some Observations on Uterine Fibroids.

SOCIETY OF ANÆSTHETISTS (20 Hanover Square, W.).—Paper:—Dr. Silk: Anæsthesia in Abnormal and Constrained Positions.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—4 p.m. Dr. H. Tilley: Clinique. (Throat.)

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.:—Dr. R. Radford: Medicine. 3.15 p.m.: Mr. McGavin:—Surgery. Out-patient Demonstrations. 10 a.m.: Surgical and Medical. 12 noon: Skin.

SATURDAY, NOVEMBER 3rd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m. Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. Out-patient Demonstrations. 10 a.m.: Surgical and Medical. 11 a.m.: Eye.

Vacancies.

Down County Infirmary.—House Surgeon. Salary £60 per annum, with board, &c. Immediate application to D. Smith, Registrar. See advt.

Grimsby (County Borough).—Medical Officer of Health. Salary £500 per annum. Applications to W. Grange, Town Clerk's Office, Great Grimsby.

St. Bartholomew's Hospital, Rochester.—House Surgeon. Salary £110 per annum, with board and residence at the hospital. Applications to Frederick F. Smith, Clerk to the Trustees, 42 High Street, Rochester.

Clayton Hospital and Wakefield General Dispensary.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Barnstaple.—North Devon Infirmary, Devon.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Chairman, House Committee.

Barnsley.—Beckett Hospital.—House Surgeon. Salary £100 per annum. Applications to Ralph F. Pawsey, Hon. Sec.

Nottingham City Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with apartments, board, &c. Applications to the Medical Superintendent.

Sheffield Royal Infirmary.—Secretary. Salary £400 per annum. Applications to the Chairman at the Infirmary.

County and City Infirmary, Waterford.—House Surgeon. Salary £100 per annum, with board, &c. Applications to E. O'Farrell, Secretary. (See advt.)

Fermanagh County Hospital.—House Surgeon. Salary £52 per annum. Applications to C. Wilson, Secretary. (See advt.)

Appointments.

CURTIS, H. J., B.S., M.D.Lond., F.R.C.S.Eng., Assistant Surgeon to the Metropolitan Hospital, Kingsland Road, N.B., and Clinical Assistant to the Throat and Ear Departments of the London Hospital.

FARNCOMBE, EDGAR LEONARD, M.B., B.Ch.Oxon., Deputy Medical Officer for the Chudleigh District by the Newton Abbot Board of Guardians.

FLEMING, ROBERT JAMES, M.B.Irel., Medical Officer to the Central District of the Devonport Union.

JACOBSEN, G. O., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Arnesby District of the county of Leicester.

KENNEDY, J. M. P., L.R.C.S.Irel., L.K.Q.C.P.Irel., Certifying Surgeon under the Factory and Workshop Act for the Tullamore District of King's County.

KENSINGTON, Miss E. GLADYS, M.B., B.S.Lond., House Surgeon to the Royal Free Hospital.

KLUMPP, ERNEST GEORGE, M.B., B.S.Durh., Medical Officer of Health for the Cricklade and Wootton Bassett (Wiltshire) Rural District Council.

LATHAM, HENRY, M.B.Edin., C.M., B.Sc. (Public Health), Physician to the Peterborough Infirmary.

LEDINGHAM, ALEX., M.D., D.P.H.Aberd., Medical Officer of Health of the county of Banff.

MCCASKIE, H. B., M.B.Cantab, M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

MENCE, W. C., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Perranporth District of the county of Cornwall.

ROSS, J. MURRAY, M.B., B.S.Durh., Clinical Assistant to the Chelsea Hospital for Women.

WALTERS, H. P., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Chudleigh District by the Newton Abbot (Devon) Board of Guardians.

Births.

ALLAN.—On Oct. 25th, at Ardrossan, the wife of W. Carrick Allan, M.D., of a daughter.

MAYBURY.—On Oct. 20th, at Hampshire Terrace, Southsea, the wife of Lysander Maybury, M.D., M.Ch., of twin sons.

POLLOCK.—On Oct. 19th, at Valetta, Malta, the wife of Major C. E. Pollock, R.A.M.C., of a daughter.

SPOONER.—On Oct. 26th, at Coupar House, Blandford, the wife of W. Casswell Spooner, M.B., etc., of a son.

Marriage.

THOMPSON—WANSEY.—On Oct. 27th, at St. Alban's Church, Streatham, Arthur Ralph Thompson, F.R.C.S., Demonstrator of Anatomy, Guy's Hospital, London, and fourth son of Vincent T. Thompson, Esq., barrister-at-law, Leeds, to Florence, daughter of the late A. H. Wansey, Esq. solicitor, Bristol.

Deaths.

CHESMAN.—On Oct 25th, at Llandewy, Radnorshire, Edward Chesman, L.R.C.P., L.M., L.R.C.S., aged 61.

CHURCHILL.—On Oct. 26th, at Netherwood, Guildford, Ellen Louisa, wife of Surg.-General A. F. Churchill.

FURNELL.—On Oct. 27th, at Lee, Emily, widow of William Anthony Purdell, Physician-General Bombay Army, retired.

SMYTH.—On Oct. 26th, at 3 Grosvenor Gardens, Tunbridge Wells, Spencer Thomas, M.D., F.R.C.S.Eng., etc., eldest son of the late Admiral Spencer Smyth, R.N., aged 86.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, NOVEMBER 7, 1906. No. 19

NOTES AND COMMENTS.

A "Sporting" Offer.

IN a contemporary last week appeared the following advertisement:—"Man, 31, healthy, interesting medical history, willing to undergo any operation where sporting outside chance of recovery; highest offer; genuine.—Address, &c." As this strange proposition came out in the "agony column," one would have thought it a mere *jeu d'esprit* put in by some practical joker to see what replies it would draw, if the newspaper itself had not sent a representative to interview their sporting patron. The result of the interview duly appeared in the editorial columns, and from it one learns that the advertiser was an ex-soldier, who, after turning his hand to various jobs since he left the Service, is now working on a farm in Somersetshire. He seems to have undergone many vicissitudes, for besides being a soldier and agricultural labourer, he has taken a turn at painting, and even given piano-lessons!

And Morbid Surgery.

THE interesting point for a medical man is to realise that there are people in the world who fancy that surgeons find zest in operating on their fellow-subjects, the sort of morbid delight that Bob Sawyer exhibited in demonstrating his prowess with a loaf of bread and a knife. We do not read of carpenters filling up their spare time by chopping up valuable bits of furniture, or joiners maliciously diverting themselves with tampering with the beams of houses to see how many people will be killed by the fall. Nor, we imagine, do surgeons as a rule spend their leisure in looking out for likely subjects to mutilate. What operation could conceivably be done on a perfectly healthy man, even though furnished with an interesting medical history, passes our comprehension. Perhaps this versatile genius will help us to a conclusion.

A Judge on Advertising Methods.

LAST week there were two important events in connection with improper advertising which ought to put energy into those who, like ourselves, desire to see a proper supervision kept over announcements made for the purpose of trade. At the Old Bailey, Judge Rentoul, in sentencing some American swindlers to penal servitude, said certain organs of the press, whether intentionally or not he could not say, had assisted the prisoners in their operations. A leading article had appeared in a prominent financial journal which praised the company, and, said the judge, if the paper had been imposed upon it was their duty to remove the writer of that article from their staff altogether. Counsel for the paper said that an action was pending against his clients on this score, but that they had acted *bona fide* and would welcome any action brought. The judge made the interesting suggestion that if the papers which had inserted the advertisements would help to recoup those who had been swindled, he would lay the matter before the Home Secretary to see if he would reduce the prisoners' sentences.

And Press Responsibility.

Now, this responsibility of the press is one of the hardest points to bring home with regard to quack advertisements. However obviously fraudulent these may be, the newspapers shrug their shoulders and say it is not their business to enquire into claims of the goods advertised, and they leave it to the judgment of their readers. Now not only does the case mentioned show the judge's opinion on the negligent admission of advertisements, but in another case the editor of a paper was actually convicted of publishing improper advertisements. The cheap press that circulates in the houses of the poor and lower middle classes knows perfectly well that its clients have not sufficient discrimination to distinguish between the "catchy" fraud and the genuine article, and in publishing misleading advertisements it undoubtedly renders itself *particeps criminis*.

The Business Side of Medical Practice.

THE straitened incomes of medical men are still providing a burning topic for Fleet Street. A vast quantity of printer's ink has been shed, but the flood of correspondence shows no signs of abating, and those who take the trouble to follow the subject will be rewarded by many a caustic comment and shrewd observation. One gentleman, who signs his name in full over the letters, "M.D.Lond.," contributes a letter of three-quarters of a column to the *Standard*. One of his main points is that the profession of medicine must be approached on a business footing. £1,000 must be devoted to education, and £500 to the purchase of a practice, or to the cost of working one up. We should say that in the majority of cases the sums mentioned are insufficient for the purpose. We heartily agree, however, that the medical man who starts in

practice without being able to command the requisite amount of capital is thereby heavily handicapped at the outset of his career. Ordinary prudence dictates the same amount of caution that regulates the choice of law, divinity, or the public services as a means of gaining a professional livelihood.

High Aims and Empty Pockets.

ENTHUSIASM and learning will not compensate for the lack of initial capital. It is true they are invaluable aids in developing a practice, but they fail when it comes to the question of laying the foundations. The crucial period for the beginner is that spent in waiting while the grist comes to the mill, and that is precisely where the shoe pinches in so many instances. Too often the enthusiast has to learn in the school of bitter experience that the mere nobility and self-sacrifice of his professional life will not bring him a living. On the other hand, anyone with an average amount of brains and a moderate capital can make sure of a fair income as a medical practitioner. Indeed, the command of an independent income confers comfort in general, and confidence in consulting and special practice, while it is almost an absolute essential nowadays for the prosecution of long-continued original research work.

LEADING ARTICLES.

FOOD INSPECTION.

OF late the public mind has been much exercised upon the purity of its food supplies, to which their attention has been somewhat forcibly directed by the American "tinned meat scare." If the spirit of wholesome enquiry be thereby stimulated the work of the sensational novelist, Mr. Upton Sinclair, will not have been altogether wasted. Briefly stated, he asserted that in the United States certain firms concerned in the preparation of preserved meats carried on their business under conditions seriously menacing to the health of the consumer. As America does a large export trade in the canned meat sent to the United Kingdom, these alarming statements naturally caused a profound sensation on this side of the Atlantic. Results were immediate and far-reaching. American tinned goods fell to zero prices, and that particular trade still reels under a blow from which it will take some time to recover. The moral of the exposure is that in the long run it is only honest and upright trading that can endure. Only those American manufacturers who have kept their house in order have been able to defy criticism, and will continue in the uninterrupted enjoyment of a great and lucrative trade. But the scare has had a good effect in causing the public health authorities of the United Kingdom to look more closely into their own methods. There can be little doubt that the food supplies of our own country are subject to a vast amount of adulteration and of dangerous contamination of various kinds. There is no such thing as a proper scientific control of the many slaughter-houses, and meat markets, and the resulting damage to the community must in the aggregate be indeed great. The law affecting the control of food is in many ways contradictory, anomalous, insufficient, and altogether unsatisfactory. Public health authorities have not yet made up their minds upon so simple a point as to whether tuberculosis is spread by the flesh and milk of tuberculous animals. So that a probable source of contamination, to state the case mildly, is going on unchecked in our midst. Of what use is it building princely sanatoria to treat a few better-class consumptives when we have not taken the trouble to ascertain so elementary a fact in the causation of the malady? This attitude demonstrates to perfection the want of logic in many of our insular notions. However, some light gleams through the melancholy darkness when we reflect that in spite of faulty methods of popular reasoning British sanitation has hitherto led the van among the nations of the world. Presumably there is something in the common-sense national grip of affairs that has instinctively seized upon and enforced the essentials of the situation. Nevertheless, it is to be hoped that in the near future a somewhat larger measure of science may be introduced into our methods. In the matter of meat inspection, for instance, would it not be infinitely wiser to have a band of scientifically-trained inspectors, who would have, as in Germany, command of laboratories, furnished with all necessary modern appliances of physical, chemical, and bacteriological investigation. As a rule the British meat inspector, when he exists, is a man absolutely without scientific training, to whom a miscroscope or a culture tube would be as much a thing unknown as to a negro of Central Africa. We are glad to see that the medical officers of health are turning their attention seriously to the necessity of a closer supervision of our food supplies. At their recent annual meeting an able paper was read upon the subject by Dr. George Newman, medical officer for the Finsbury District of London. He first of all very wisely advocated certain reforms that are urgently needed in the law. Among many other important things advocated by him the following may be specially noted: After seizure of suspected articles careful examination should be made by the medical officer of health, full notes taken of the pathological condition of the meat, and before any further proceedings are taken the vendor should have ample means of examination. There should be a gradual extinction of private slaughter-houses and a rigid system of marking and stamping all inspected meat, home or foreign. Foreign meat should be required to comply absolutely with English standards, and there should be some guarantee that the meat had passed a proper inspection, and no boxed, boned, or pieces of meat should be admitted if packed or prepared in a way to prevent inspection. More adequate inspection of tinned meats and similar foods is urgently needed. There is evidence of much unwholesome preparation by no means confined to America. Even in London he had come across tuberculous pus put into widely advertised sausages, diseased horseflesh into potted meat, and decomposing animal matter into potted salmon and shrimp. The only way of effective administrative control of the preparation of these and various other foods is by inspection

at the time of manufacture of the constituents of the prepared foods and of the premises, and there should be a distinctive inspection mark. Name and date of canning should be stamped on every tin. The regulations necessary for the protection of the consumer would require fresh legislation. Fish, oysters, ice-cream, watercress, milk, eggs, and other articles require the exercise of scentific common-sense control in all stages of storage and distribution. Of a truth Dr. Newman's remarks seem calculated to awake the echoes in many a municipal quarter. Those who are interested in the subject—and who is not?—should make a careful study of the article in the original.

A STATE MEDICAL SERVICE FOR IRELAND.

THE first volume of the report of the Commission to consider the working of the Poor-laws in Ireland is one of the most important documents issued for some time. The Commission has been working for the past three years, and has collected an enormous amount of evidence which will be published in a later volume. The Commissioners have made a very large number of recommendations, many of which are of a sweeping character. We shall refer to the majority of these in another place, but here we desire to draw public attention to one which, in our opinion, possesses the greatest interest for medical men in Ireland. The Commissioners unanimously recommend a complete reorganisation of the Poor-law Medical Service. A State medical system is advocated, the entrance to which, at all events for the present, should be restricted to candidates educated in Ireland. A competitive examination for entrance should be held and conducted on lines similar to those for the Navy and Army Medical Services. The Service should be controlled by a Council composed of five members as follows:—The Medical Commissioner of the Local Government Board, a representative of the Royal College of Physicians and of the Royal College of Surgeons in Ireland conjointly, a representative of the Irish Branch of the General Council of Medical Education and Registration of the United Kingdom, a medical representative from the University of Dublin, and a medical representative from the Royal University of Ireland. Our readers do not require to be told that this is a reform the necessity of which has long been urged in these columns. The present system of electing medical officers in the Poor-law Service is nothing short of an insult to the profession, and is derogatory to the self-respect and medical qualifications of the applicants. We are quite aware that the proposal of the Commissioners will give rise to considerable difference of opinion, and for this reason we appeal to the medical profession in Ireland to give the matter their serious attention. Can any member of the profession conscientiously say that under the present system the medical qualifications of the candidates receive due consideration? Can he say that the conditions under which the newly-appointed medical officer holds his post are such as are due to a man who has spent hundreds of pounds and five years of his life in learning his work? Can he say that the future prospects of the medical officer are those to which his education and a faithful discharge of his duties entitle him to look forward? Can he, in short, give any reason save one why the present system is worthy of continuance? The opponents of a state service will bring forward the old objection that the power of electing should not be removed from "the people," and that no change was sought when the mode of election was vested in the old Dispensary Committees. They will further say that medical officers would find themselves far worse off in a State Service than at present. The first objection is scarcely consistent with the present trend of opinion in Ireland. The very people who object loudly to a State Medical Service, with competitive entrance, are those who cry equally loudly for the creation of competitive examinations for clerkships in railway companies and such commercial undertakings. Why should what is right in one case be wrong in the other, when the conditions are almost identical? The second objection cannot stand examination any more successfully than the first. If any man thinks that it is tenable, will he compare the conditions under which a medical man lives and discharges his duties in the Public Services and in the Poor-law Service. To the one he is appointed on his professional qualifications and on those alone; he receives a salary on which he can live from the day he enters the Service; his salary increases by regular increments; and when he has served for the necessary term of years, he receives a gratuity or pension and is allowed to retire. Look at the other side of the picture. The candidate for a post in the Poor-law Service knows that his professional attainments will be the last matter considered by the electors; he receives a starvation salary; save in a few cases, no regular increments of increase are assured; and even when, from no other cause than old age, he has become incapable of working, his chances of a pension are but small. When medical officers are advised to oppose a State Service, we urge them in their own interest to consider the question well, to contrast the conditions in their own Service and in the Public Services, and to refuse to be guided by the professional politician.

NOTES ON CURRENT TOPICS.

The Treasury and "Professor" Richard.

THE successful prosecution of the notorious electrical quack, "Professor" Richard, at the Stafford Assizes last July was hailed by the MEDICAL PRESS AND CIRCULAR as a hopeful sign of the times. The Watch Committee of the Wolverhampton Town Council appointed a sub-committee to consider the question of costs. A representation was subsequently made to the Treasury, drawing attention to the great public importance of the prosecution, and to the fact that witnesses had been brought from all parts of the country.

In the face of these facts it was urged that to throw the whole of the costs upon Wolverhampton would be unfair. It is most satisfactory to be able to announce that the Treasury have adopted that view of the case, and have agreed to pay the whole of the expenses, amounting to about £500. The official attitude is a most hopeful and encouraging feature of the case. Were prosecutions of quacks to take place on any systematic and general scale the country could be cleared of these pests of society within a few years. Obviously the knowledge that they themselves would have to pay the costs of prosecuting any quack, however injurious and fraudulent, who might settle in their midst would make many a local authority hesitate to saddle their ratepayers with a burden in defence of what are really the interests of the community.

Placenta or Blood Clot.

A CASE of some importance to medical practitioners was recently investigated in the East Ham Coroner's Court. A young married girl, sixteen years of age, died after being attended in her confinement by a certificated midwife from a nurses' home. A *post-mortem* examination was made by a Dr. Bourke, who stated that he found a great portion of the placenta in the womb. Evidence to a contrary effect, however, was given by Dr. John Phillips, described in the newspaper reports as "an expert," who gave his opinion that the supposed placenta was a clot of blood that had led to septic poisoning. Dr. Bourke thereupon produced a report from the Clinical Research Association to the effect that the specimen submitted to them was placental structure, and he offered the Coroner a microscopical slide for his own satisfaction. The jury returned a verdict of death from natural causes. The Coroner has refused to re-open the case. From various points of view the results of the investigation are far from satisfactory. Dr. John Phillips may have good reasons for arriving at his declared conclusion, upon which the verdict of the jury was based. In the face of the report by the Clinical Research Association, however, it would have been more reassuring if he had furnished some reason for the extraordinary discrepancy.

Bad Oysters and Distinguishing Marks.

A NUMBER of cases of illness arising from bad oysters have been recently reported. In one instance brought under our personal notice a distinguished London physician was attacked with symptoms of severe ptomaine poisoning, fortunately without serious results. This matter of unwholesome oysters has been before the public health authorities of the United Kingdom for many years. It has been fully reported upon by the inspectors of the Local Government Board, who showed that the choicest native oysters from Whitstable, Hayling Island, Southend, and other places were often bedded and stored under filthy and dangerous conditions. Every now and then a scandal arises, usually in connection with a public dinner. The bacteriology of the subject has been adequately studied. Yet in spite of all this knowledge oyster poisoning continues. A similar state of affairs would not be tolerated in the case of any other ordinary foodstuff. The Belgian Government are now advocating the imposition of a mark denoting the place of origin of the oyster. That is the precise step that the MEDICAL PRESS AND CIRCULAR has advocated for many years past. If the Government were to insist upon a distinguishing mark being affixed to oyster-shells there would soon be an end to bad oysters. Meanwhile, the oyster trade has been half ruined, and a few more scares will practically extinguish it altogether.

The Royal College of Surgeons, England.

The annual report of the Royal College of Surgeons, England, can always be relied upon to contain some interesting details in respect to the progress of the College, and the "Calendar" which has just been published for the current year is no exception to the rule. Formerly the most prominent feature which claimed attention was the proceedings in connection with the contest of the "Body Corporate" with the Council, when a powerful section among the Fellows laid hands upon the old-time traditions of the College, and sought to induce the Council to apply for a new charter, in order that there might be less conservatism and more democracy in the government of the College. But for some years now a serenity bred of a satisfied ambition has prevailed between the Fellows and the Council; so much so that the question of reforming the Council by the election of Fellows pledged to democratic views has ceased to be thought of. Still the members, it should be added, have their grievances against the Council, but these, such as they are, are only of service to certain of the agitator members, who are thus afforded an opportunity of making a speech at the annual meeting of Fellows and Members. The most interesting item in regard to the College is the financial statement. The balance of income over expenditure amounts for the past year to £2,329, a most satisfactory record. Seeing the important national duties which the College undertakes, and the valuable fabric which it maintains, it is essentially gratifying to learn how sound is its financial position. There are now on the roll of the College 1,363 Fellows and 17,424 Members, besides 2,016 Licentiates in Dental Surgery, and 578 Diplomates in Public Health.

The Late Mr. George Herring.

BY the death of Mr. George Herring the nation has been deprived of a great philanthropist. In his early days he amassed a fortune of £50,000, which he afterwards converted into millions by legitimate operations upon the Stock Exchange. Always a shrewd business man, he was careful to inquire about the practical side of the charities to which he devoted large sums during his lifetime. His methods might be studied with advantage by many philanthropists, both as to their current and their testamentary benefactions. One of the institutions that benefited most from his generosity was the Hospital Sunday Fund, to which he gave an annual donation of £10,000 from 1899 to 1901. Then he offered to add 25 per cent. to their receipts, up to £25,000. In that way sums varying from £11,000 to £12,400 have been sub-

scribed. In all the Fund has received about £100,000 of his wealth. Mr. Herring was also honorary treasurer of the North-West London Hospital. He built and endowed the Home of Rest for Gentlefolk, the Twentieth Century Club for working ladies, and other charitable organisations. Amongst other things, he handed over £100,000 to the Salvation Army Home Colonisation Scheme. His carefully considered generosity affords an excellent example to benevolent folk, who are apt to think that, having given their money, all further responsibility as to its distribution is at an end.

Lunacy in London.

The Report of the Asylums Committee of the London County Council for the year ending March 31st, 1906, was issued last week, and to the scaremongers who have been trying to frighten people into the belief that national insanity was merely a matter of time, this volume will act as a check. We have frequently pointed out the many causes at work which have produced the increase in the numbers of the certified insane, the chief of which is the disposition of the poor to send their old people suffering from senile decay to the asylum. Although this action may bespeak a lack of independence on their part, it is a high testimony to the improved conditions of asylum life. Moreover, as the large outstanding number of senile dements becomes absorbed into the normal asylum population, the rate of increase of lunacy must drop. This process, which began in London last year, is much more plainly visible in the present report, the actual numbers of persons in asylums for the last five years being:—

		Increase on previous year.
1902	21,255	786
1903	22,052	797
1904	23,948	996
1905	24,652	704
1906	24,957	305

Thus it will be seen that whereas the increase in 1904 amounted to nearly a thousand, this year it has fallen to only just over three hundred. Unless some unforeseen improvement occurs, one must expect, in a population growing so rapidly as that of London, a normal increase in the number of the insane. It is comforting to find that the rate is decreasing so satisfactorily.

Windsor District and its Drainage.

The district of Windsor is perhaps one of the wealthiest in the country, the neighbourhood, besides being particularly pleasant, offering to rich people the advantages that flow from proximity to Royalty. Under such circumstances one would have imagined that the amenities of life would have been specially cared for by the inhabitants and their representatives on the council. Far from this being the case, Dr. Petronell Manby has lately made a report to the Local Government Board on the sanitary circumstances and administration of the Windsor Rural District, from which one would gather that that smiling countryside has little to boast of beneath the surface. After describing his investigations on behalf of the Board, Dr. Manby writes that the council will have to decide whether they will adopt a drainage system or institute wet-scavenging, which latter will be obsolete in a few years' time, and concludes:—"As the result of a detailed inspection of the district, I am satisfied that the present sanitary condition of Ascot, Sunninghill, and Sunningdale leaves much to be desired." It is wonderful in what respect people hold the outside of the platter!

Medical Reports to Public Officials.

The exact legal and moral relation of doctor and patient is a matter of great delicacy. In private practice questions frequently arise which tax the judgment to the utmost, but in public appointments even more difficulty is experienced. The ordinary common-sense view that the person who pays a doctor for his opinion is the person entitled to that opinion, is not always a safe one to put into practice. A case involving a very delicate point was tried in Glasgow lately. Dr. Boyd, the Corporation Police Surgeon, appears to have diagnosed the illness of one of the constables as of venereal origin, and duly reported his diagnosis in the usual way to the Chief Constable. The constable was indignant, as he denied the accusation, and he brought an action for slander with damages assessed at £1,500. Now, unfortunately, it appears from the report that the diagnosis was doubtful, if not positively mistaken, and Dr. Boyd was consequently placed in rather an invidious position. However, the judge took the clear-sighted view that even if the diagnosis were erroneous, and even if the examination were not sufficiently searching, there was in these facts no evidence of malice or recklessness. The case was therefore dismissed. It is most desirable that a medical man's position in relation to confidences of this kind should be rigidly defined.

H.R.H. Princess Louise has consented to open the new wing of the London Throat and Ear Hospital, on November 13th.

Mr. Richard F. Tobin, F.R.C.S.I., has been appointed by the Lord Lieutenant to be Secretary to the Board of Superintendence of Dublin Hospitals. Mr. Tobin is an ex-president of the Irish Medical Association and Surgeon-in-Ordinary to the late Viceroy.

Dr. E. G. Thomas, late civil surgeon to the Guards Depot, Caterham, on the termination of his appointment, has been the recipient of a presentation by the officers of the Brigade of Guards and other friends.

Dr. Thomas Reid was recently entertained to dinner by a few of his old house surgeons in the Glasgow Eye Infirmary, and presented with an address congratulating him on having reached his professional jubilee. Dr. Reid was also presented with a silver bowl, and Mrs. Reid with a silver salver.

Our Scotch correspondent writes us that the Glasgow Town Council at its meeting last week was the first authority to make consumption a notifiable disease.

A CLINICAL LECTURE ON LATENT DISEASES. (a)

By Professor POTAIN, M.D.,

Of the Faculty of Medicine and University of Paris.

By latent diseases we mean diseases the existence whereof is hidden from the physician and the patient by reason of its insidious onset or because it assumes the characteristics of some other malady. Here is a case in point.

A woman was recently admitted into my wards with cardiac dilatation. She had been under my care in 1894 for rheumatic endocarditis. While she was in the hospital the heart was very carefully examined with the following results: There was at first blurring, then disappearance of the second sound with the appearance of a systolic murmur. The nature and the seat of the changes indicated the existence of inflammation of the aortic and mitral valves. The lesion of the aortic valve was of short duration and the sounds gradually returned to their normal pitch. Only the mitral *souffle* persisted, and it was not very loud. That was her state when she left us.

But now she presents all the signs of pronounced cardiac hypertrophy. This fact was of a nature to cause surprise, because the mitral murmur, never very well marked, pointed to a lesion too slight in itself to determine so much hypertrophy. Dilatation of the heart, as you know, only occurs quite late in mitral disease, just the contrary to what happens in aortic mischief. We were therefore fain to seek some other explanation for this dilatation. The patient died from heart failure, and at the *post-mortem* the necessary explanation was forthcoming in the existence of extensive adhesion of the pericardium, which was glued together by thick, tough, quasi-cartilaginous fibrous tissue. The mitral valve, much deformed, showed many milky patches. The water test showed leakage limited to two spots. In addition to the valvular insufficiency there was slight narrowing due to adhesion of the valve segments over an area of a few millimetres. This is usual, for in almost every instance mitral insufficiency is associated with some degree of narrowing.

The principal lesion in this patient, then—that which determined the cardiac dilatation, which was the only perceptible symptom during life—was the pericardial adhesion. It ran quite a latent course, and this proves the importance of being on the look-out for latent diseases. I propose to go into this subject somewhat in detail.

On thinking the matter over, the first thing that strikes one is the importance of the semiology. Every disease is recognised by its own particular symptomatology, and it is to these symptoms that we must look for guidance. It is, however, not enough to know that such and such a disease is manifested by such and such symptoms. We must distinguish those symptoms which are common to other diseases and seek the means of differentiating them in each case.

Symptoms may be divided into two main classes: (1) functional, (2) physical. The functional signs consist in disturbances of the organism, and these are the symptoms which first attract the attention of the patient and lead him to seek advice. The physical signs are those which the physician alone can detect and identify, and these he only looks for when the functional signs suggest the probability of this or that morbid process.

With respect to semiology the medical science of to-day differs greatly from that of the past. Our forefathers in the art knew practically nothing of physical semiology, which only occupied an insignificant place in the art of the physician who was not in possession of the means of elucidating them. At present we are in possession of these means, and our methods of exploration have been so multiplied and perfected that the study of physical signs has acquired an immense and deserved importance.

Our knowledge of the physical signs of disease does not go so very far back. We ought possibly to mention the works of Auenbrugger on percussion, translated by Corvisart in 1808, but the work was done for the most part by Lænnec, who in two years created, so to speak, a new and complete science, almost unknown to his predecessors, *viz.*, the science of auscultation. Physical semiology, you see, only dates back about a century, which is but a brief period in an art of which Hippocrates was the father.

Although antiquity was inferior to ourselves in the matter of semiology, you must not run away with the idea that our forefathers despised the investigation of the objective signs of disease. Hippocrates strove perseveringly to discover the signs of changes in the organs, and if he does not give us the means of establishing the existence and the significance of physical signs he at any rate pointed out the object we must have in view, which consists in observing in the patient "everything that can be seen or heard or smelled." Are not these the desiderata furnished by percussion, inspection and auscultation?

It is no exaggeration to state that Lænnec founded a new science. Instruments *per se* do not constitute a progress. Auscultation and percussion can exist very well without the invention of the stethoscope and the pleximetre. Auscultation and percussion are real sciences, and if the ancients did not discover them, it was because they lacked the knowledge which is the indispensable corollary of the investigation of physical signs, *viz.*, a knowledge of pathological anatomy. Now pathological anatomy did not exist in antiquity for the simple reason that dissection of the dead was not permitted. Rondelet, of Montpellier, was the first to examine the bodies of dead patients. Charles Bonnet, in 1779, it is true, made observations in pathological anatomy, but he only called attention to certain curious facts: "a stone in the brain," "a bone in the heart," and so on. Pathological anatomy can only be said to have become an exact science in the hands of Dupuytren, Cruveilhier and Lænnec, who looked upon these researches as inseparable from the study of semiology. How, indeed, can we discover the physical signs unless we know in advance to what lesions they correspond?

Of course, in the present state of our science we cannot expect to find physical signs in diseases of inaccessible organs such as the brain and spinal cord, for which reason there will always be plenty of scope for functional signs. But the latter may be wanting, and so you will understand how certain diseases may remain latent for a longer or shorter time, sometimes till death, running their insidious course in the tissues without giving rise to any subjective or objective signs.

Latent diseases may be divided into three categories: (1) latent diseases, properly so-called, which reveal their presence by no functional or physical sign; (2) undeveloped diseases; and (3) diseases which are masked by or simulate other diseases.

Among diseases which belong properly speaking to

(a) An unpublished lecture by the late Professor Potain, specially reported for this Journal.

the group of latent diseases—*i.e.*, which most readily escape our observation—may be mentioned cerebral tumours, cancer of the kidney, cardiac symphysis, ulcer of the stomach, and renal calculi. At the museum of Montpellier is a specimen removed from a man who died without having presented any cerebral symptoms, although as a matter of fact a dagger had penetrated the brain after passing through the skull. It is by no means uncommon in old people to discover stones in the kidneys which have never given rise to any obvious symptoms. I can recall an instance in which a large calculus embedded in, and quite filling, the kidney pelvis was never suspected during life. Miliary tuberculosis of the lung may run a silent course, witness the case reported by Kelsh in which he made the *post-mortem* examination of a man "in excellent health." Pericardial adhesion and pleural adhesion may both remain "latent" for long periods of time, and the same remark applies to chronic atrophic nephritis which sometimes runs a dumb course until it culminates in an attack of uræmia.

Many affections based on an atrophic lesion, stricture &c., can only manifest themselves in consequence of an effort which directs attention to the diminution of functional capacity. For instance, Gibert, of Havre, remarked that infants with intestinal stricture remain in good health so long as they live on milk, but as soon as they begin to take solid food their troubles commence.

To this state of reduced functional capacity I give the name "Miopragia" from the Greek *meion*, deprivation.

Mitral stenosis sets up a state of circulatory miopragia which does not cause trouble until an unusually strong effort determines a much larger stream of blood.

Among undeveloped diseases I may mention persistent diarrhœa of malarial origin. I have seen many such which yielded only to quinine. Malaria, indeed, assumes many other masks.

The predominance of one particular symptom may lead us into error. In a case that came under my observation a certain hospital surgeon was long thought by his colleagues to be suffering from some grave cerebral affection. He was subject to attacks of giddiness so severe that he was fain to cling to the bedposts when going his rounds in order to avoid falling down. Careful auscultation revealed the fact that he had pronounced aortic insufficiency.

The third group—that of masked or simulated diseases—comprises the majority of the cases which differ widely. First, maladies really simulated by hysterical women, or for more serious reasons: marriage, life insurance, conscription, &c. A more interesting group are those in which a disease is masked by a concomitant affection or by a complication, or, simpler still, by a collateral symptomatology that directs attention to a more or less distant organ. I have often warned you of the erroneous interpretations that these various modifications may give rise to, but here are a few examples: You are aware that pulmonary emphysema may mask the physical signs of pulmonary tuberculosis with which it is frequently associated. In the same way great difficulties present themselves when aortic insufficiency is associated with mitral stenosis.

Patients are often ignorant that they are suffering from some gastric affection. A doctor who was troubled by his heart was radically cured by merely washing out the stomach, the cardiac disturbances being directly caused by the unhealthy condition of that organ, in spite of the fact that so far as he was aware his digestion was excellent. It is by no means unusual in such cases for the clinical picture to be that of heart disease, with palpitations, dilatation of the right heart, cardiac liver, ascites, œdema of the lower limbs and syncopal attacks. Yet when we correct the gastric trouble all the cardiac symptoms disappear.

Affections of the stomach, then, may exert such an influence on the circulatory apparatus as to give rise to the suspicion of heart disease, but the converse is equally true, and cardiac disease may be manifested at first merely by gastric symptoms. These facts are of course familiar to you, but there is one symptom of circulatory disturbance that merits special attention—*viz.* diarrhœa. Some patients suffer from persistent refractory diarrhœa without any other trouble or discomfort. We naturally ascribe the symptom to an intestinal affection, whereas our patient may be suffering from heart disease. I recently saw a case of this kind with Dr. Guyot. The patient complained only of obstinate diarrhœa, and on examination I discovered abdominal aneurism to which he succumbed shortly after.

Cardiac affections may simulate a purely hepatic affection when the symptoms are limited to the liver—ascites and œdema. In other instances, especially in mitral lesions, they may present deceptive nervous symptoms.

In gastric affections, too, we sometimes meet with vertigo, migraine, and even typical apoplectiform attacks. I remember a patient who suffered from attacks of this kind whose only trouble in reality was defective teeth with deficient mastication and consequent indigestion. Stomach cough is a symptom we must be on the look-out for, because when it is associated with emaciation we are apt to suspect incipient tuberculosis. We must also bear in mind the gastric origin of pseudo-asthmatic attacks due to bronchial or vascular spasm, or to urticaria of the bronchial mucosa.

Intestinal parasites give rise to the most varied symptoms, In the adult the presence of tænia in the small intestine may lead to mental aberration, kleptomania, &c. As soon as the worm is expelled reason and morality are restored. A naval officer, previously a man of extreme courage, was one day seized with inexplicable fear, so that he dared not weigh anchor. The ship surgeon, surprised at this extraordinary and unusual display of timidity, enquired into the officer's health, and found that he had worms. He administered a vermifuge, and thereupon the officer recovered his normal temperament.

The reaction of intestinal affections on the heart gives rise to strange errors: colitis, for instance, may simulate a heart disease. Hepatic affections have a more or less marked influence on the nervous system, hypochondria being one of the forms. They also give rise to cardiac symptoms and to signs compatible with disease of the lungs. In one case a hydatid cyst of the postero-superior part of the liver gave rise to a dry cough and steady emaciation, leading to the suspicion of phthisis. I recently saw an instance of this in a young tuberculous subject.

Biliary calculi are not infrequently mistaken for cancer of the stomach. Billroth was just about to operate in a supposed case of gastric cancer when I ventured to diagnose calculous cholecystitis. The patient died, and *post mortem* we found a calculus that had determined inflammation of the gall-bladder with consecutive peritonitis. I saw another case with Guéneau de Mussy. The patient, who was of cancerous family history, presented a tumour, and as a matter of fact she died later of cancer. Nevertheless, at the date of our examination she was not cancerous, as was proved by the fact that a season at Aix cured her, and she came back with a bottleful of gallstones passed by her.

On the other hand, certain lesions are manifested by similar symptoms simply because they occupy the same region, in which case the diagnosis may be of extreme difficulty. What can be more difficult, for instance, than to distinguish between cerebral anæmia and cerebral congestion? Andral and Grasset describe their symptoms as being identical. The mechanism of the malady is different, but the effects are approximately the same. In the former, too little blood gets into the vessels, and in the other too much, but the ultimate result—*e.g.*, blood stasis—is the same.

Hæmorrhage and brain softening can only be differentiated by the circumstances in which the disease has supervened. If the patient was previously suffering from atrophic nephritis the evidence would be in favour

of hæmorrhage, whereas if the patient was atheromatous we should opine in favour of softening.

In diseases of the lungs it is often difficult to differentiate cancer from tubercle.

Confusion may also arise between disease of altogether different organs when they happen, as is sometimes the case, to give rise to the same disturbances. Pulmonary congestion gives rise to syncope and apoplexy just as does cerebral congestion. This coincidence is often seen in the aged who succumb to apoplexy, and in whom *post mortem* we find commencing pneumonia. Exactly the same thing happens when large pulmonary emboli suddenly block the circulation.

Tuberculosis at its onset often determines palpitations calculated to make us suspect cardiac disease and so turn our attention from the real lesion. At a later stage this disease may cause the same mistake on account of the dulness over the pre-cardial area, due to the presence of indurated pulmonary tissue, suggestive of cardiac hypertrophy, while the oppression and the œdema of the lower limbs due to respiratory embarrassment may likewise be ascribed to a cardiac lesion. Dulness of the sclerosed pulmonary tissue at the apex may lead to the diagnosis of an aortic lesion.

I need not carry this enumeration further, though I could do so without difficulty. If I have insisted somewhat forcibly on the subject, if I have made a point of bringing before you numerous examples, it is in order to convince you of the importance of a careful exact examination of all cases. You will remember that subjective semiology, fruitful of errors, is for the most part of but slight assistance in arriving at an exact diagnosis, and that the physical signs, of vastly greater importance and significance, must also be carefully scrutinised—in short, that we must always seek to establish the reciprocal subordination of the morbid elements in order to reduce the chances of error to a minimum.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The Lecture for next week's issue will be by J. Magee Finny, M.D., F.R.C.P., King's Professor of the Practice of Medicine, on "Erethema Induration."*

ORIGINAL PAPERS.

SOME NOTES ON FAMILY DISEASES. (a)

By T. K. MONRO, M.A., M.D., F.F.P.S.G.,

Physician to the Glasgow Royal Infirmary, and Professor of Medicine in St. Mungo's College.

GENTLEMEN,—In his presidential address last year, my distinguished predecessor in the occupancy of this chair discussed one of the most important principles connected with the doctrine of inheritance, and after making his own position clear, proceeded to indicate the bearings of the question upon many of the diseases to which mankind is liable. On the present occasion, I venture to bring under your notice a subject which is no doubt intimately connected with the question of heredity, but which lends itself to be introduced by the statement of a very simple theory, which, in turn, can immediately be illustrated by an appeal to clinical experience.

It might seem that the most natural mode of dying is to die of old age, and yet this is one of the rarest modes we meet with. Even those who escape the infections and their results seldom die in this way. No doubt if we could combine the advantages of civilised and uncivilised life, and eliminate the disadvantages of either, this would happen more frequently than it does. But too often a particular tissue or organ undergoes decay prematurely, with the result that the whole organism dies at a time when many of its parts are in good condition and fit for many years' service, or are, at most, altered secondarily to the one that broke down. This premature decay is often seen in the case of the arteries, and while it is frequently due to the disproportionate strain put upon these structures during life, it is well known that certain families shew a strong tendency to sufier from the results of arterial disease (*e.g.*, cerebral hæmorrhage and softening), while other families shew a striking degree of immunity from such evils. But the kind of premature decay to which I wish specially to refer this evening is that which occurs before the age of 40 or 45, when the degenerative period of life may be said to commence in the average individual. For instance, *aneurism* has been met with in different members of a family (*e.g.*, in two brothers) in early adult life. Some of the best illustrations, however, are encountered when we study the diseases of muscles.

In *muscular dystrophy* we see a disease, or group of diseases, which depend on a defective power of development in the tissues from which the voluntary muscles are derived. The developmental power is sufficient for the growth and activity of the muscles for some time after birth, and even it may be for a good many years; but it fails at length, and then the muscular fibres gradually waste away. While this is happening, the interstitial tissue behaves in different ways. It often undergoes an increase, and this may or may not be sufficient to compensate, so far as bulk is concerned, for the loss of the muscular fibres. Sometimes the interstitial tissue flourishes to an extraordinary degree, becomes infiltrated with fat, and actually renders the part more bulky than if it had been absolutely normal. This disease, then, is due in one sense to a congenital defect. It shews itself during the period of growth—some time between infancy and maturity—and it is often met with in several members of one family. In the case of the variety which is characterised by increased size of the weakened muscles (pseudo-hypertrophic paralysis), the usual, though not invariable arrangement is that the males suffer from the disease, while the females transmit it. In the other varieties the sexes suffer almost equally. In the pseudo-hypertrophic type the muscles which are most apt to be enlarged are those of the calves, and next to these the infraspinati, while increase or decrease of size takes place in numerous other muscles of the limb-girdles and proximal parts of the limbs. The first symptom is weakness or awkward use of the lower limbs. The child has a difficulty in going upstairs, falls readily, and has great trouble in rising again. Yet, on examination, the weakened muscles seem well nourished, and may, indeeed, be recognisable as increased in size. One of the most striking features of the disease is the enlargement of the calf muscles and infraspinati, in combination with wasting of the latissimus dorsi and the lower part of the pectoralis major. The wasting and weakness are progressive in their tendency, and in most instances death takes place before the age of 20, very often from bronchitis or pneumonia.

In the juvenile type, the wasting generally shews itself about puberty. It begins in the muscles of the upper arm and shoulder-girdle, and afterwards attacks those of the trunk, pelvic girdle and thigh. The prognosis is not nearly so grave as in the case of the pseudo-hypertrophic type, since the patient may survive for many years.

In the facio-scapulo-humeral or infantile type, the disease may appear either in infancy or at puberty. It usually affects first the orbicularis oris and orbicularis palpebrarum. It may spread over the face, but it spares the ocular muscles and the tongue. Moreover, it spreads to the limbs and trunk like the juvenile type. It also is less grave than the pseudo-hypertrophic variety.

Another form of muscular atrophy, which is entirely distinct from muscular dystrophy, and which yet

(a) Presidential address delivered to the Glasgow Southern Medical Society on October 4th, 1906. Illustrative cases and photographs were exhibited.

commences in early life, and runs in families, is the *peroneal type of muscular atrophy*. Here the wasting is first noticed in certain muscles which are supplied by the peroneal or external popliteal nerve, viz., either the long extensors of the toes, or the peronei, but in course of time it tends to involve the distal halves of all four limbs. Double club-foot is a common result, and there may be evidence of changes in the nerves. Moreover, the disease sometimes follows an attack of measles. Whether the primary flaw is in the muscles, or in the nervous system, or in both, is not yet known; but the disease marks a transition, from the point of view of classification, between the developmental defects of the muscular and those of the nervous system.

The motor path, or the path taken by the voluntary impulses passing from the brain cortex to the muscles, consists of at least two segments. The upper of these extends from the brain to the spinal cord, and the lower from the spinal cord, by way of the nerves, to the muscles. Premature decay sometimes occurs in one or other or both of these segments, but this is chiefly observed after full maturity has been reached. When the lower segment is involved, the condition is known as *chronic spinal muscular atrophy*, or *progressive muscular atrophy*. In rare cases, decay of this segment occurs in the developmental period, either in infancy or later, and sometimes in different members of a family. Similarly, decay of the upper segment, which is known clinically as *primary spastic paraplegia*, has also its analogue in cases which occur in early life and in several members of a family. Some cases of *cerebral* or *spastic diplegia* seem to be manifestations of a similar developmental flaw in the brain.

The disease known as *amaurotic family idiocy*, or *infantile cerebral degeneration*, may be described as a special variety of cerebral diplegia. So far as is known, it is almost confined to the Jewish race. It is frequently seen in several members of a family, it begins at about the age of three months, and it usually ends fatally within two years. Weakness begins in the muscles of the neck, and spreads over the trunk and limbs, which are at first flaccid but afterwards stiff. The muscular weakness is accompanied by mental deterioration, and optic atrophy and blindness also supervene. A distinctive feature of the disease is seen with the ophthalmoscope in the macular region, where there is a large greyish white area, with the cherry-red macula in its centre. The characteristic symptoms of this deadly disease are accounted for by the degeneration of neurons whose cells are situated in the cerebral cortex and retinæ, and whose axis-cylinders run in the pyramidal tracts and optic nerves.

Friedreich's disease or *hereditary ataxy* also begins in early life and runs in families. It is characterised by degeneration in the posterior and antero-lateral columns of the cord, and among the early symptoms are unsteadiness and weakness of the legs with loss of the knee-jerks. The weakness and inco-ordination gradually increase, and extend to the upper limbs. Later on, there are oscillating movements of the head and trunk when the patient sits up or tries to move. Defective articulation, nystagmus, club-foot and spinal curvature are other very important symptoms. Though the disease is incurable and progressive, it has but little tendency to cause death directly.

If now we turn to the region of the cranial nerves, we encounter *Leber's atrophy* or *hereditary optic atrophy*. This is a family disease which, like pseudo-hypertrophic paralysis, is apt to attack chiefly the males, though it is transmitted by the females.

In certain families, again, there may be *defect* or *poor development of the external ocular muscles*, in consequence, as is supposed, of a corresponding defect in the cells of the nuclei from which the nerves of these muscles take origin.

The essential element, then, in the various nervous diseases or degenerations to which I have referred, may be regarded as a premature decay of neurons, or nerve-cells with their processes, comparable to that which overtakes the muscle fibres in muscular dystrophy.

The tendency to attack several members of a family is displayed by other diseases of the eye than those connected with its nerves and muscles. *Retinitis pigmentosa* is a family disease associated with slowly progressive atrophy and pigmentation of the retinæ. The first symptom is inability to see well at night. The visual field shrinks in extent from the periphery inwards, until the patient may be unable to find his way about, though still perhaps able to read in a good light, or, at any rate, to see well in a straightforward direction. A considerable number of these patients are the offspring of consanguineous marriages. *Cataract* occurring in childhood and in families points to a similar defect of endurance in the lens.

Daltonism or *colour-blindness* and *albinism* may be mentioned as other diseases which show a tendency to appear in different generations of a family, or in different members of a family in one generation; but as these are not manifestly due to premature decay of tissues after birth, and are therefore not to be included in the category with which I have been dealing, they need not be further considered at this stage. The same remark applies to *congenital deafness* and to various *bodily deformities*, as well as to what has been described as "the most hereditary of all hereditary diseases," viz., the *hæmorrhagic diathesis*.

An excellent illustration of the class of disease I am speaking of is seen in that rare and curious malady *Xeroderma pigmentosa* or *Kaposi's disease*—excellent because, while a genuine family disease, it is almost never inherited. It confines itself, as a rule, to one generation in a family. While it attacks males and females with almost equal frequency, it commonly keeps to one sex in a particular family. Here the premature decay occurs in the skin, possibly, as Mr. Hutchinson suggests, under the influence of sunlight (as in the case of retinitis pigmentosa). In the first or second year of life, pigment-spots develop in the skin, exactly resembling freckles, both in their appearance and in their tendency to involve chiefly the uncovered parts. In the course of some months, or it may be years, dilated blood vessels become visible between the pigment-spots. Small, white, atrophic areas develop among the freckles on the face. Warts, many of them like the familiar flat, yellowish-brown, senile warts, also put in an appearance. Ulcerations take place, and lead to crust-formation and cicatricial deformity. Finally, tumours develop in the warts and ulcers, at first of a papillomatous, but ultimately of an epitheliomatous nature; and these multiple cancers naturally lead to a fatal issue unless they can be removed in time.

Among diseases of the skin which may be quoted as shewing both hereditary and family tendencies is *Ichthyosis* or *fish-skin disease*. This is characterised by great scaliness of the epidermis, and in exceptional instances the scales or plates are wart-like, and project so much that the patients have exhibited themselves at shows as "porcupine men." This was done by several members of the well-known Lambert family, in which the disease affected numerous males belonging to three or four generations.

Tylosis is another disease which exhibits the same two tendencies. It consists in a great overgrowth of the horny epidermis of the palms and soles. Ichthyosis and tylosis, however, can scarcely be regarded as illustrating premature decay of particular tissues; indeed, they are rather more allied to congenital malformations.

I may mention here, without further dwelling on the condition of *cystic kidneys*, which has been observed as a family affection; and also *Bright's disease*, which may shew either a family or a hereditary tendency, or both.

Nobody knows exactly what constitutes the carbohydrate-assimilating mechanism, but we know that in cases of *glycosuria* it is overtaxed, and that in diabetes this disablement is present to a serious

extent. In January, 1905, I had under my care a boy who was suffering from diabetes, and who recovered under treatment so that he became able to use a considerable amount of carbohydrate without glycosuria being induced. After he left the infirmary he relapsed, and he died about five months ago. He was one of five members (three brothers and two sisters) out of a family of twelve who had died from that disease, but no other relatives are known to have suffered. It would seem that in this particular family the carbohydrate-assimilating mechanism is liable to become worn out before the period of puberty is reached.

Glycosuria may of course be part of an inherited predisposition, as well as part of a family tendency.

Albuminuria of an innocent kind may occur in different members of a family. The most common variety is that which is known as orthostatic or postural. When the individual rises in the morning, the abrupt change to the upright posture so disturbs the circulation in the kidneys that they are unable for a time to prevent the escape of albumen with the urine. In normal individuals this does not happen; either the circulation accommodates itself more quickly to the change of blood-pressure which results from the change of posture, or the function of the glomerular epithelium is less disturbed by the change in the circulation.

Gout is a disease which is apparently due to a reduction in the capacity of the uric acid excreting mechanism in the kidneys; but this does not usually manifest itself before middle life. It shews both family and hereditary tendencies. It occurs mostly in males, and may, moreover, be transmitted by females who do not themselves suffer.

A rare and very interesting family peculiarity is the condition known as *spontaneous pentosuria*. Pentose is a sugar whose molecule contains five atoms of carbon, just as the glucose or dextrose of diabetic urine is a hexose containing six carbon atoms. These people regularly excrete pentose, even when their food contains none. The condition is evidently not a disease, but an anomaly of metabolism.

Cystinuria is another condition which may occur in families. Though it is rare, it is nevertheless important because it may give rise to urinary calculus, and thus compel some individuals to undergo repeated operations. Cystin is a normal intermediate product of proteid metabolism, and if given to normal individuals is all changed in the body. One theory of cystinuria is that it results from an anomaly of metabolism in the particular individual, but it has also been suggested that the cystin is due to an intestinal mycosis.

Alkaptonuria is perhaps as striking an example as any of an abnormal variety of proteid metabolism. The urine, when fresh, is highly acid and of normal colour; but it becomes darker on exposure, till it is reddish-brown, dark brown, or even black. Urine of this kind reduces Fehling's solution, but the fermentation, polarimetric, phenyl-hydrazin and bismuth tests are all negative. Alkaptonuria is harmless, and usually congenital and life-long. It is a family disease, but is rarely inherited. A large proportion of cases occur in children of parents who are full cousins, but who are not themselves affected. The peculiar characters of the urine are due to the presence of homogentisic acid, which is a normal intermediate product of the breaking down of proteid matter. Alkaptonuria may, like cystinuria, be looked upon in the light of what Garrod appropriately terms a "chemical sport."

Albinism is not so much an abnormal form, as a defect, of metabolism. It consists in the failure to produce pigments of the melanin group. It affects males more than females, is a family rather than a hereditary defect, and is sometimes met with in the children of first cousins.

In connection with anomalies of excretion and metabolism, it is appropriate to refer to anomalies of another important function—viz., muscular movement. Simple *tremor*, for instance, may be met with as a family and a hereditary affection, beginning it may be, at puberty, or later, and persisting throughout life. *Thomsen's disease* likewise possesses both family and hereditary tendencies. It has existed in the family of Thomsen, who is himself a sufferer, for at least five generations. Both sexes are liable, and the symptoms are usually first noted in childhood. The most characteristic feature is the tonic spasm of the muscles which occurs on first attempting to use them after a period of rest.

(*To be concluded in our next.*)

THE TUBERCULOUS AND THEIR HYGIENIC SURROUNDINGS AT HOME.

BY D. T. BARRY, M.D.R.U.I., D.P.H.

THE report of the Commissioners of National Education in Ireland for the year 1905-6 shows a most deplorable condition of school hygiene. The cramped space, lack of seats, and provisions for cleanliness, etc., form indeed a sorry picture. The scourge of tuberculosis which has ruined and is ruining the health of so many thousands of our stunted population, finds in such conditions a very potent form of sustenance.

However, I do not intend to deal with school hygiene in this contribution, which is merely a record of some personal observations of the sanitary conditions existing in the homes of tuberculous individuals in the south of Ireland. My excuse, if excuse be needed, for adding to the literature on the prevention of tuberculosis is that too much cannot be written or said anent this evil till a definite diminution in case incidence and case mortality occurs. We seem to get no nearer with time to a solution of the difficulty. Facts observed during our management of such cases, whether they point to success or failure, if systematically recorded would help materially to a better condition of things.

I shall give here a brief account of the actual conditions found in a few examples, with occasional reference to the general treatment adopted. Some of the cases came under my own care. Many others I was permitted to see through the courtesy and kindness of the medical men who had charge of them, and who have also allowed me to refer to them in this article.

CASE I.—J. K., a boy, æt. 5. Enlarged glands, felt in both lumbar regions, diarrhœa, night sweats, pallor, wasting, slight cough. A sample of sputum was obtained with difficulty, and examined for bacilli, which were not found. The house possessed two rooms, one of which was entirely occupied by an old invalid woman. The other room was used as kitchen and bedroom, accommodated three individuals, and exhibited the following: window, 18in. by 24in., could not be opened; large cumbersome covered-in bed which had remained unchanged in the same dark corner for many years; earthen floor with sundry tiny pools of water, one of which was located under the bed and overgrown with moulds. Plenty of good food was available, and the mother, by a little persuasion, carried out suggestions made. The window was with difficulty forced open, an improvised bed for the little patient was placed beside it, and he was regularly sponged. In a few months the cough and diarrhœa had ceased, and the appetite was improved.

CASE II.—D. M. This was an instance of pulmonary tuberculosis in a man of 24 years. A sample of sputum which I was permitted to take showed numerous T.B. The medical attendant had only recently been consulted, and had not so far an opportunity of examining the dwelling. This showed a very unsatisfactory state of things. He slept in a covered-in bed with a younger brother; the room was small, and its window was not made to open. The room was boarded, but presented numerous holes, patches of "dry rot," and musty odours. The subsequent history of the case I do not know

CASE III.—J. F., a boy of 12 years, who suffered from tuberculosis of the ankle-joint. He was a thin, pale, wasted youth, with poor appetite, cough, and sputum. No signs of phthisis were evident in the lungs, and no bacilli were found in the sputum. Here a small room, which had originally been boarded, but which at the time of observation presented a few bits of board in the form of "stepping-stones," served as sleeping-room for five people. What had been a window at one time was almost completely boarded up, and admitted very little light but no air. The boy was put in the kitchen, which possessed a window, to live. The joint was lightly scraped, and cleanliness enforced. In the course of two months the cough had disappeared, the appetite and general condition were better, and the joint was fast healing.

CASE IV.—J. C., a young man 23 years, one of a family of six, who inhabited a four-roomed house. He had been accustomed to sleep with a brother in a small, badly-ventilated room. The apex of the left lung showed signs of solidification; he had coughed up some blood, and had evening rise of temperature. The sputum showed many bacilli. A parlour was given over to him as bedroom, he was forbidden to sit in the kitchen at night, and cold sponging was adopted. In six weeks the cough was much improved, the bacilli did not seem quite so numerous, and the appetite was better. The physical signs were unchanged.

Of patients treated in sanatoria in Ireland I have practically no experience, but during nine or ten years of English practice I had to deal with a good many so treated in English institutions. It is the after treatment of such patients that concerns us here. They have been educated, so it is said, in hygienic principles, and they know the value of fresh air and cleanliness. In theory the majority of them do; in practice many do not. Their education soon yields to the exigencies of limited space and other inconveniences; the good habits inculcated gradually lapse, and the evil once more gets a hold. The most persistent supervision on the part of the medical attendant fails to keep some minds up to the scratch on these points, and yet we must depend on such supervision for ultimate success.

We shall always have tuberculous cases to treat in their own homes. They may have already been in a sanatorium, or they may be unable or unwilling to gain admission to one.

In most cases of early phthisis it is the custom of the patients to consult the doctor at the dispensary, or at his private residence, where good advice is always given, but not always followed. Those cases which are regularly attended at their homes are usually far advanced in the disease, and though sound hygienic principles which are enforced tend to check the spread of the mischief, it is usually too late for the patients to derive permanent benefit from them. In the early stages of the disease irreparable damage is done. While the doctor's advice may be fairly conscientiously followed in the matter of ventilation, of isolation, and of cleanliness, yet hitches occur. Baths are occasionally neglected, a little rain or wind provides a reason for shutting windows, and the attractions of the social circle in the hot, stuffy kitchen or parlour, prove too many for the invalid. Man is ever a gregarious animal.

The regular cleansing of the skin by sponge baths is a regular *bête noir*. Yet many practitioners who are sufficiently insistent succeed in enforcing this very useful form of treatment. It is cheap, and can be adopted in the very poorest cabins. It is only in few cases that the procuring of good food forms an insuperable difficulty. Such cases we cannot with any hope of success treat at home.

Honorary Fellowship of the R.C.P.J.

AT the annual meeting of the Royal College of Physicians of Ireland, held on St. Luke's Day, Dr. John W. F. Tatham was admitted to the Honorary Fellowship of the College, to which he had been previously elected. At the same meeting, Dr. Daniel J. O'Connor, Physician to the Mercy Hospital, Cork, was elected to the Fellowship, to which he was admitted on the 2nd inst.

THE SIMPLE EXTRACTION OF SENILE CATARACT BY TEALE'S METHOD.(a)

By CHARLES G. LEE, M.R.C.S.,
Surgeon, Liverpool Eye and Ear Infirmary.

IT may seem a somewhat uninteresting subject to many that I am about to bring briefly under your notice, but after all it is possibly as important to all of us to know by what method an opaque lens may be best removed as to learn which is the better route by which to reach a stone in the bladder, or how best to amputate a thigh. Whether these things are so or not, the question has been one of surprising interest to ophthalmic surgeons, from the time of De Beer right through the Von Graefe period to the present. Many expedients have been adapted to this end, but their enumeration would be beyond the limits of these notes.

One of the most important points to determine is: Shall an iridectomy form part of the operation for extraction, or shall the cataract be removed without cutting the iris? Von Graefe's incision being placed so far back made it almost imperative to cut off a portion of iris, otherwise a large prolapse and subsequent incarceration of iris would take place. The incision at present in vogue, "the three millimetre flap" of De Wecker, although not so far back, is placed at the periphery of the cornea, and is open to similar consequences. The excision of iris itself proves a complication in the technique, for the effusion of blood that necessarily takes place into the anterior chamber obscures the next step in the operation, viz., laceration of the lens capsule. Notwithstanding, there remains a goodly number of expert operators who still adhere to this complicated procedure.

On the other hand, many operators have escaped this difficulty by performing the iridectomy some days or weeks before the extraction. This method has much to recommend it; for, although it requires two sittings for its completion, it makes less demand on the patient's self-control, and enables the operator to see clearly what he is doing. It is a procedure much favoured by my valued colleague Mr. Richard Williams, and one that I have myself chiefly adopted for many years.

While this, and much more which might be said, is admitted, it remains that two operations, when one may suffice, doubles the risk from sepsis. The loss of an eye, following a preliminary iridectomy, which happened in my private practice last year, brought this danger so strongly before me that I determined to try if some other method might not serve equally as well in results, and without this grave possibility. Before this time I had on several occasions performed the simple operation for extraction, and had still more frequently seen Mr. Edgar Browne accomplish it with great brilliancy; yet, from time to time, one's own experience confirmed the words of that well-known Dublin oculist, C. H. Swanzy, who says, "The extraction without iridectomy exposes the eye to the serious danger of prolapse of the iris into the wound." This danger, then, always imminent, deterred me from the ordinary simple extraction.

Some twenty years ago I was privileged to observe the practice of Mr. Pridgin Teale in Leeds.

(a) Read before the Liverpool Medical Institute.

He was then extracting the lens without an iridectomy, and by means of an incision quite novel to me. Since that time I have been able to see Mr. Teale operate occasionally, and also Mr. R. N. Hartley, who adopts Mr. Teale's method. After each visit I have wished to emulate these gentlemen, but a prolonged practice of the combined method had conferred a certain amount of confidence, if not dexterity, in that method, so that I hestitated to forsake it.

The unfortunate occurrence to which I have already alluded determined me to attempt Mr. Teale's operation; and during last session I submitted for the inspection of this Society the first five persons on whom I had operated. To-night I give particulars of these, with three additional ones, making eight in all.

Before considering these cases, it will be well to indicate some features in which the operation differs from others, and what advantages its adoption appears likely to offer. All these things have been plainly set forth by its author in the Bowman Lecture for 1893, and may be read at large in volume xiii of the Ophthalmological Society's *Transactions*, from which record I shall extract such portions as may seem necessary to our better understanding.

There are two important characteristics—

1. The knife employed.
2. The site of the section.

On these two depend all the subsequent details.

The knife is one modified by Mr. R. N. Hartley, and very much resembles Taylor's cataract knife: it is much deeper in the heel than elsewhere in the blade; it is also thicker in this situation, more or less of a wedge; by virtue of this it retains the aqueous in its passage across the anterior chamber, and also lessens the tendency of the iris to double over the blade, advantages which the narrow knife of Graefe does not possess. The incision is situated altogether in the corneal structure; and, as this fact, added to the method of making the section, constitute indispensable

FIG. 1.

conditions of the operation, I cannot do better than quote the author's own description:—

"The point of the knife enters the cornea just within the outer margin at its equator, and emerges at a counter-puncture just within the inner margin of the cornea, at a level about two millimetres above the equator. As soon as the counter-puncture is well accomplished, and the point of the cataract knife has passed

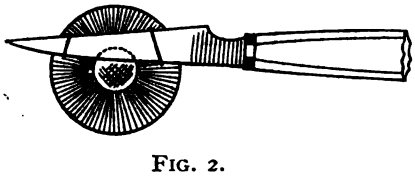


FIG. 2.

out of the cornea to the extent of about four millimetres, the next step is taken. This is the most critical part of the operation.

"The knife is somewhat rapidly and with a sort of knack turned directly forwards so that the blade, which up to this point has been parallel with the iris, comes to a right angle with the back of the cornea. The section is completed by cutting directly forwards, this final cutting being vertically through the corneal thickness, absolutely linear, and in position about midway between the horizonal equator and the upper margin of the cornea. The incision thus made is practically a shallow flap, chiefly linear, with a small limb at an obtuse angle, corresponding to the heel of the knife at the outer edge of the cornea, and a still smaller, hardly perceptible limb, corresponding to the point of the knife, at the inner edge of the cornea.

At the limbs the knife passes through the cornea obliquely, but in the horizontal linear part it cuts vertically through the corneal structure."

From a consideration of the section and its position, it will be seen how unlikely it is that the iris should be prolapsed; indeed, not much more than the edge of the iris is extruded at the time

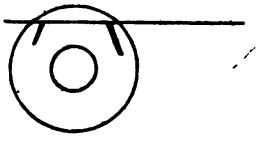

FIG. 3.

of the delivery of the lens, which is in marked contrast to what happens when the line of incision is laid at the circumference of the cornea. The edges of the wound, by reason of the incision being for the most part vertically through the cornea, fall into such accurate apposition that healing takes place rapidly, and there is no need for a conjunctival flap to prevent the ingress of bacteria.

It may seem that some difficulty might be experienced in acquiring this knack of turning the knife; and I may confess that this thought prevented me from attempting the operation years earlier, a fact which I much deplore. If we get, and maintain, the point of the knife well through the cornea, on no account withdrawing it as the turn is made, no difficulty will be experienced; and as neither conjunctiva nor iris has been wounded, the proceeding is absolutely bloodless, and therefore every step is clearly seen.

There remains little more to add. The eye had better not be disturbed for dressing, unless pain is complained of, for from three to eight days. In three of my patients the first dressing was done on the eighth day, and in none earlier than the third. Usually neither eserine nor atropine is required, nor is it imperative that the operator should be ambidextrous.

The visual results obtained in these eight cases are as follows:—

1 attained $\frac{6}{6}$
3 " $\frac{6}{9}$
1 " $\frac{6}{12}$
1 " $\frac{6}{18}$
1 patient too illiterate to responds to tests, but counted fingers length, opened, off some 30 feet.

In only one case did the operation call for any comment. In it, owing to the restlessness of the

patient, the iris was wounded when the point of the knife was crossing its surface, but the vision obtained was $\frac{6}{18}$; and as the other eye had been operated upon by the combined method, with $\frac{6}{60}$ as a result, the advantage rests with the simple extraction.

During the healing process one of the patients (Mary M.), the third night after operation, severely knocked her eye and re-opened the wound, causing an escape of aqueous enough to thoroughly damp the pads, which were changed, but no further mischief resulted, and the vision obtained is $\frac{6}{9}$.

Another patient's (Henry M.) eye was dressed for the first time on the eighth day; after the removal of the pads the eyelids were seen to be swollen, and when separated a free mucous discharge escaped: evidently he had a smart attack of catarrhal conjunctivitis. The incision was firmly healed, and cornea quite clear; his vision is $\frac{6}{9}$.

These two cases incidentally prove the value of Teale's incision; in other case we should have had in one prolapse of iris, and in the second probably suppuration of the wound.

I have made no attempt in these remarks to exhaust every argument that might be advanced in favour of this procedure; my wish has been to demonstrate that it is at once a simple and efficient method of operating in most cases of senile cataract; that its results, even when advanced by one not accustomed to the method, will bear comparison with those obtained by other and often more complicated ones; and that, although it is neither German nor American in its conception, it is well deserving of trial by all who desire to advance the art of ophthalmic surgery.

Tabular List of Cases.

Name.	Age.	Eye.	Date of Operation.	Visual Result.	Remarks.
Michael M'H.	70	Right	13 Oct. 1903	D D c̄+9⊃+2 cyl. axis vertical. V=$\frac{6}{9}$.	First dressing eighth day after operation.
John H.	65	Left	20 Oct. 1903	D c̄+9⊃+1.75 cyl. V=$\frac{6}{9}$.	First dressing eighth day after operation.
Mrs. M'A	56	Left	14 Nov. 1903	c̄+9⊃+2.50 cyl. V=$\frac{6}{9}$.	Patient knocked her eye violently during third night after operation; loss of aqueous, but no prolapse.
Mary E.	51	Right	12 Jan. 1904	c̄+11 3+2^{a} cyl. V=$\frac{6}{12}$.	No remarks.
Henry M.	67	Left	12 Jan. 1904	c+9 3+2^{a} cyl. V=$\frac{6}{9}$.	First dressing eighth day. When pads were removed, lids very swollen, profuse mucous discharge from between lids. Cornea quite clear. Wound healed.
Thos. A.	68	Right	13 March, 1904	c̄+10^{a}. V=$\frac{6}{18}$.	Iris pierced by knife in its passage across anterior chamber. Patient very restless.
Sarah H.	68	Right	15 Aug. 1904	Approximately say, $\frac{6}{18}$	Dressing eighth day. Some adhesions posterior. Patient both illiterate and unintelligent; could not respond to tests, but counted fingers reading at 6 metres.
Mrs. B.	78	Left	4 Oct. 1904	Sees time on watch.	Done so recently. January 1895. V–$\frac{6}{9}$.

CLINICAL RECORDS.

CASES OF DISEASED NASAL CAVITIES AND CASE OF EXTRA-DURAL ABSCESS WITH SEPTIC SINUS THROMBOSIS.

Under the care of J. GALBRAITH CONNAL, M.B., F.F.P.S.G.

Lecturer on Aural Surgery in Anderson's Medical College, Glasgow

CASE 1.—*Sphenoidal Sinusitis.*—Patient, man 36 years of age, who complained of nasal obstruction and discharge in right nostril of many years duration. He thought the trouble originated in an attack of measles when he was six years old. During school life he was troubled with greenish crusts coming down his nostrils and often into his throat. When the secretion of pus stopped he had severe pains, referred sometimes to the forehead, sometimes to the back of the ear, and sometimes to the neck. When the headaches were severe he became sick, and often felt dull and sleepy.

Examination showed in the right nostril that the pus had caked, and formed a crust over the middle turbinal. There was also pus noticed in the nasopharynx.

The middle turbinal was removed under cocaine anæsthesia, and the anterior wall of the sphenoidal sinus exposed, when pus was seen welling out of its ostium. The anterior wall of the sphenoidal sinus was broken down with Hajek's hooks. At the junction of the roof and back wall of the cavity an area of carious bone was detected with the probe. This was gently curetted. The opening speedily contracted, and caused a recurrence of his headaches, and for a second time a fairly large opening was punched out of the anterior wall.

The discharge is now less, and his headaches are greatly better.

CASE 2.—Patient operated on for combined empyemata of the maxillary antrum, the frontal, the ethmoidal and sphenoidal sinuses.

Came under observation with profuse purulent discharge, and feeling of obstruction in the left nostril. The middle turbinal was greatly hypertrophied, and it was removed. Pus was seen coming from all the accessory cavities on the left side.

CASE 3.—Patient from whose left nostril a large sarcomatous tumour was removed three and a-half years ago, in whom there has been no recurrence.

Man 59 years of age. Seen for the first time in February, 1903. The tumour extended from the anterior nares to the posterior choana. It probably originated at the posterior extremity of the turbinal and spread forward, becoming attached to the septum and to the floor of the nose. The tumour was removed at several sittings with the scissors and cold snare, the septal attachment being cut through with the electric cautery. After removal of the tumour the parts were thoroughly cauterised with the electric cautery. This was done three and a-half years ago, and there has been no recurrence. Sections of the tumour showed it to be spindle-celled sarcoma, with an admixture of round cells.

CASE 4.—Patient on whom the radical mastoid operation was performed for purulent otitis media. When seen for the first time patient had a primary diphtheria of the external auditory canal.

Boy, twelve years of age, with purulent otitis media, dating from infancy. The left ear had a perforation in the postero-superior segment of the tympanic membrane, with slightly offensive discharge. On the posterior wall, and partly on the floor of the external auditory canal, there was a whitish membrane. A part of the membrane was sent to the Corporation Bacteriological Department, and reported positive. Swabs from the nose, nasopharynx and pharynx were reported negative. Temperature was 101.2° F.; pulse, 120; urine normal, free from albumen.

After a period of several weeks the radical mastoid operation was performed for persistent pyrexia (Ambulatory enteric was excluded). A carious area

* Abstract of notes on patients shewn at Glasgow Medico-Chirurgical Society, on October 19th, 1906.

was found in the antrotympanic passage and floor of the antrum. After the mastoid operation his convalescence was retarded by a slight attack of subacute rheumatic fever (pains in the joints and temperature up to 103.8), which yielded to salicylate of sodium. The after-history was uneventful. Mastoid wound healed, and there is a dry cavity in the ear.

The points of interest in the case are the persistent pyrexia before operation and the primary diphtheria in the ear, which is very rare. Diphtheria in the ear, secondary to diphtheria of the nose, pharynx or nasopharynx, is not so rare, the infection taking place through the Eustachian tube to the middle ear.

CASE 5.—Case of purulent otitis media, with extradural abscess and septic sinus thrombosis.

Man 21 years of age, with purulent discharge in right ear of two years' duration; in left ear of six weeks duration. Severe pain in the left ear for past eight days; severe rigor the day before admission to hospital.

Left mastoid was opened. Foul-smelling pus was found between the tegmen and the dura. On working backwards pus was liberated over the sigmoid sinus. Three days later, after a severe rigor, the internal jugular vein was ligatured, and the lateral sinus split open and found to be filled with greyish clot.

The patient died some days after. The post-mortem showed effusion in both pleural cavities, multiple abscesses in the lungs, and purulent clot in the vein and in the lateral sinus.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

OPERATION FOR PERFORATED GASTRIC ULCER.—MR. PEYTON BEALE operated on a woman, æt. 25, who had been admitted with all the typical symptoms of perforated gastric ulcer. There was a previous history of some years' duration of gastric ulcer. The patient was suffering very severely from shock, but it was not thought that there was any hæmorrhage going on, and so it was assumed that the shock was alone due to the perforation, and the consequent escape of stomach contents into the peritoneal cavity. The patient was put to bed and surrounded with hot bottles. She was given strychnine and a little brandy, and in about two hours she was much less collapsed. An incision was then made in the left linea semilunaris, and on opening the peritoneum gas and some fluid escaped. A large quantity of hot, sterile water was poured in, the hand being introduced into the abdominal cavity in order to move the intestines about freely, and so to wash out the cavity. After this had been repeated three or four times, the stomach was drawn out through the wound and carefully examined. A thickened patch, surrounded by inflamed tissue, was felt about the middle of the lesser curvature. Whilst Mr. Beale was examining this to see if there were any perforation in it, the house surgeon, Mr. Clarke, found a circular aperture about a quarter of an inch in diameter about an inch and a half lower down in the lesser curvature. On further examination a great deal of thickening was felt at the back of the first part of the duodenum, giving rise to a suspicion that there was an ulcer there also. The edges of the circular aperture were pared with scissors, and the borders of the stomach muscle brought together with three or four silk sutures. External sutures were then passed through the peritoneal covering of the stomach so as to completely cover over the previous line of sutures. The peritoneum and abdominal wound were closed, with the exception of a small aperture through which a gauze drain was passed. The patient was then sent to bed, ordered to be kept very warm with hot bottles, and to have a hypodermic of morphia directly she began to regain consciousness. She was ordered to have hypodermics of morphia as often as might be necessary in order to keep her absolutely quiet—in fact, to keep her in a state just short of coma. Mr. Beale said that he considered the first thing to be done in all abdominal cases in which there was any severe shock, providing it were not due to hæmorrhage, was to get the patient thoroughly warm and to watch the pulse so that directly it began to regain strength, the operation might be performed. The operating table should be one capable of being warmed, and the patient's extremities should be kept wrapped up in cotton wool. No more anæsthetic should be given than was necessary to make the incision through the abdominal wall, and when this had been done the peritoneal cavity should be repeatedly washed out with hot sterile water or normal salt solution. As a rule, he pointed out, nurses in the theatre did not make the water hot enough. They prepared it at a temperature of about 107° F., but by the time it got to the peritoneal cavity it was rarely over 80° F. He therefore preferred the water so hot that one could only just bear the whole hand to be plunged into it. The effect of washing out a peritoneal cavity with such hot water was most remarkable, and exceedingly rapid. He did not believe in any attempt to completely wash out the cavity. With regard to sewing up the perforated ulcer, it was, he considered, of no use to put in a great number of stitches, as the coats of the stomach were so hard and œdematous that they would not bear many efficient sutures. He believed in a few sutures of thickish silk not passing through the mucous membrane; his view was that lymph was poured out along the line of sutures within a very few hours, and that this effectually prevented any leakage; the more stitches one put in the greater was the risk of their all cutting through. As regards the anæsthetic, the less administered the better; patients must have some during the incision through the abdominal wall, and also during the suturing of the same, but they need not have any in between. As regards after-treatment, he believed in absolute rest, such as could only be secured by morphia given every two hours. It was advisable, he thought, to administer hot nutrient enemata every eight hours during the first thirty-six hours after operation, but after that period he gave liquid food by the mouth. He had adopted this line of treatment during the last three years, and it was very noticeable how well very severe abdominal cases, particularly perforated gastric ulcers, progressed under it. There was another point, he said, worth considering in a busy hospital ward, namely that the patient, when continuously under morphia, made no noise and gave no trouble.

A fortnight after operation the patient is doing perfectly well, and has had no bad symptom of any sort.

CANCER HOSPITAL.

CARCINOMA OF THE BODY OF THE UTERUS.—VAGINAL HYSTERECTOMY.—Mr. BOWREMAN JESSETT operated on a woman, æt. 36, who had been admitted into the hospital suffering from menorrhagia. She thought she had had a miscarriage about three months ago, when she had experienced a considerable loss of blood, several clots coming away at the same time. She had since been suffering from dysmenorrhœa, losing small quantities of blood mixed from time to time with a slightly purulent discharge. She had some twelve

months ago had a good deal of pain, and was told she had retroversion of the uterus; for this she wore a ring for a year. She had also suffered a good deal from bearing-down pains since her last child five years ago. She was a stout, healthy-looking woman. Abdominal examination revealed nothing. *Per vaginam*, the body of the uterus was found to be enlarged, and there was considerable erosion of the os, a foul discharge coming from the cervical canal. The tissues of the os were soft and bled readily on examination. On passing a sound into the uterus, it passed for about three inches, causing a good deal of hæmorrhage. The uterus was mobile, and Mr. Jessett considered it a good case for vaginal hysterectomy. The patient was placed in the lithotomy position, and Sims' speculum passed; the cervix was seized with vulsellum forceps and drawn down between the vulvæ. The anterior fornix was opened up with scissors and the bladder separated with the finger. Douglas' pouch was freely opened through the posterior fornix. The lateral fornices were then divided up, and, the uterus having been dragged well down, the uterine arteries on each side were ligatured with linen thread. The tissues were next divided on the uterine side of the ligatures and separated from the uterus freely. The fundus was now seized with vulsellum forceps, and drawn down through the posterior fornix. The lateral ligaments were transfixed with double linen thread, and the ovarian arteries, round ligaments and Fallopian tubes firmly ligatured. The uterus was then cut away from its attachments and removed. The anterior and posterior margins of the peritoneum were next seized with forceps and drawn well down, and the vagina packed with iodoform gauze. Mr. Jessett said that this was a typical case in which, in his opinion, vaginal hysterectomy was called for in preference to removal of the uterus by the abdominal route. The uterus was freely mobile, and the disease was evidently of recent date, and restricted to the fundus uteri. By removing the uterus by the vaginal route patients, he pointed out, made a very much more rapid convalescence; besides, the abdominal walls were not in any sense weakened, and the chances of any recurrence were quite remote. Mr. Jessett stated he had had many cases in which he had employed this method that were alive and well, and free from any recurrence, the operations having taken place from four to twelve years ago. With regard to the performance of the operation, he said that the first principle was to select cases in which the uterus was mobile, as in those cases in which the disease had extended into the cellular and connective tissue around the cervix, affecting probably also the broad ligament, this operation was not to be recommended. In such cases he did not consider that any operation, either by the abdominal or the vaginal route, could be relied upon to remove the whole of the disease, and although operations as described by Wertheim were credited with being able to get wide of all diseased tissues, including the removal of the enlarged sacro-lumbar glands, yet he would be much afraid that within a comparatively short, in such cases, time the disease would manifest itself again.

The patient left the hospital convalescent three weeks after the operation.

THE Commissioner of Health for Chicago gives statistics of mortality from diphtheria before and after the introduction of the antitoxin treatment on Oct. 5th, 1895. In the ten preceding years 10,019 deaths were reported from diphtheria, an average of 9.87 per 1,000 of population. In the next decade there were 6,446 deaths from diphtheria, an average rate of 3.94 per 10,000. Had the previous rate obtained there would have been 9,701 more deaths.

TRANSACTIONS OF SOCIETIES.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, OCTOBER 25TH, 1906.

The President, FRANK T. PAUL, F.R.C.S., in the Chair.

EXTROVERSION OF INTESTINAL MUCOUS MEMBRANE.

MR. G. P. NEWBOLT showed a patient in whom fæcal fistulæ complicating an attack of tubercular peritonitis had been cured by intestinal anastomosis. Extensive prolapse and extroversion of the mucous membrane of the small intestine, with profuse discharge of mucus now existed at the site of the old fistulæ.

Mr. R. W. MURRAY mentioned a similar case which had been under his care, in which he had successfully performed intestinal anastomosis; but the patient died 12 months later owing to an accumulation of intestinal secretion in a portion of the gut which had been completely occluded.

CÆSARIAN SECTION.

Dr. ARTHUR WALLACE read a note on Cæsarian Section, based on an experience of 16 cases, in 13 of which operation was indicated for pelvic deformity, and in 3 for obstruction by tumours. The former included four instances of the repeated operation. The maternal mortality was 6.25 per cent., the only death occurring in the case of a patient who was probably infected before admission to the hospital. The performance of every Cæsarian Section in such a way as to permit of future pregnancy was advocated.

Dr. H. BRIGGS alluded to the tedious management after Porro's operation in his earlier experience, and to the almost invariably easy recovery of the patient after Cæsarian Section in his recent practice. In one patient, whose pelvis was contracted after tubercular sacro-iliac disease, there was only an enfeebled constitution to account for the fatal shock nine hours after a smooth and uncomplicated operation in a well-equipped public hospital. In private practice he had successfully operated in three cases, and he thought it was well to appreciate beforehand the inconvenience and dangers—unexpected labour, a midnight operation, distance of locality, and lack of equipment. He preferred a clean, healthy peritoneum to utero-parietal adhesions, which were apt to be imperfectly maintained, and, if complete enough for a future Cæsarian operation, they would rarely be an unmixed advantage.

CHARCOT'S JOINT DISEASE.

Dr. T. R. BRADSHAW showed a man, æt. 37, with Charcot's disease of the ankle. The joint was disorganised, the astragalus being dislocated forwards, and the malleoli much enlarged. The condition had existed over three years, but the patient was still able to use the limb. The patient had tabes dorsalis in the pre-ataxic stage, evidenced by lightning pains, myosis, Argyll-Robertson pupils, absence of knee-jerk, and a rapid pulse. There was good reason to suspect antecedent syphilis.

GASTRIC ULCER AND DYSPEPSIA.

Dr. J. HILL ABRAM read a paper on gastric ulcer and dyspepsia. The first section of the paper dealt with the difficulties of diagnosis of ulcer, stress being laid upon failing nutrition, localised pain and tenderness, especially the "douleur en broche." Hæmatemesis could not be regarded as a decisive symptom, and cases were quoted in support of this statement in which the stomach had been examined directly. Dr. Abram suggested that the diagnosis of ulcer was made too readily by physicans, and that the strong surgical statements of recent years were due to this fact. In support of this position he quoted several sets of figures, and showed from the Liverpool Royal Infirmary reports (1896-1905) that in the medical wards out of 293 cases only 14 were males; whilst in the surgical wards out of 134 cases, 43 were males. Further, that the mortality rate in the medical wards was 4.8 per cent., whilst in the surgical wards it was 26 per cent. He then discussed the question of hæmatemesis, and stated that he had not seen a fatal case of hæmate-

mesis in simple chronic stomach patients, and also his belief that medical treatment was sufficient. Dr. Abram criticised the statement that chronic dyspepsia was, in a majority of instances, due to mechanical interference with the stomach, the result of old ulceration. In four years 127 cases of chronic stomach trouble, cancer, congestion, and the dyspepsia of tuberculosis being excluded, had passed through his wards at the Royal Infirmary. In 35 only could he admit that the symptoms or the course of the disease and the results of treatment justified a diagnosis of ulcer or its results; 13 of these had to be transferred to his surgical colleagues. In *true cases of gastric ulcer* the modern surgical position was probably sound. The common causes of chronic dyspepsia were, in his opinion, first and foremost constipation, and second neurasthenia. Dr. Abram offered proof of the mode of action of constipation, holding it to be reflex and not auto-intoxication. Finally, he emphasised the risk of classing cases of neurasthenia as examples of dilated stomach, and said that in such cases operation would do but little credit to surgery.

Dr. T. BRADSHAW said that arbitrary rules founded on the situation and character of the pain could not be implicitly relied on. In practice one treated this class of case by rest and dieting, when they almost always recovered for a time. If, as often happened, successive relapses occurred on returning to ordinary diet and mode of life, one felt bound to offer the chance of benefit from surgical interference. In a certain proportion of cases thus dealt with no benefit would result; but it was not always possible to tell before operation which were the cases not amenable to it. In this, as in other matters, experience was the guide of life, and as Sir W. Gowers had said in another connection, in order that we should be right in 19 cases, we must be content to be wrong in the twentieth. For his own part, he had always seen greater benefit from operation in gastric ulcer, and where there was no benefit he could not remember any case where the operation had made the patient worse than before.

Dr. C. J. MACALISTER thought that there should be joint action between the physician and surgeon in cases of doubt, but did not consider that hæmatemesis warranted the case being turned over to the surgeon, because the symptom did not always indicate ulceration. In the case with a history of hæmatemesis, and in which the patient had been suddenly seized with violent pain in the stomach region, giving rise to a suspicion of perforation, on opening the abdomen tubercular peritonitis and not gastric ulcer was found. Dr. Macalister related a case showing that appendicitis and gastric ulcer might occur together in the same patient without any interdependence. Constipation was not always a cause of dyspepsia; he had had many cases of severe constipation under his care in which there were no symptoms of dyspepsia. Constipation was in all probability in many cases of chronic dyspepsia an effect and not a cause. A healthy stomach meant healthy action of the intestinal glands.

The following members also discussed the paper:—Mr. G. G. Hamilton, Mr. Rushton Parker, Dr. R. J. M. Buchan, Dr. A. G. Gullan, Dr. J. Lloyd Roberts; and Dr. Abram replied.

NORTH-EAST LONDON CLINICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 1ST, 1906.

The President, Dr. A. E. GILES, in the Chair.

THE following cases and specimens were exhibited:

Dr. F. J. TRESILIAN (Enfield) read notes of a case of Pernicious Anæmia in a man in whom the chief symptoms were an intense anæmia, œdema of the legs, and great weakness. He had improved considerably under arsenic. Blood-films were shown revealing the presence of numerous poikilocytes.

Dr. A. J. WHITING showed three cases of Tabes Dorsalis in men exhibiting various symptoms or phases of the disease. One patient was practically blind from optic atrophy and yet had little or no ataxia.

Dr. G. P. CHAPPEL showed a man, æt. 49, with Dilatation of the Stomach and Severe Vomiting. He had been losing weight, and there was a small tumour to be felt beneath the right rectus muscle. He was admitted into the Tottenham Hospital, and the stomach was systematically washed out. Lactic acid was absent from the gastric contents, but free hydrochloric acid was present, together with sarcinæ. This analysis led the exhibitor to incline towards the view that the condition was one of fibrous induration around an old peptic ulcer.

Mr. WALTER EDMUNDS showed a girl, æt. 14, with Tuberculous Glands in the Neck, which had been treated by the X-rays. There was now hardly anything to be felt, whereas six months ago there were large masses in both anterior triangles. There was a marked family history of tuberculosis, and the child's brother had been operated upon for a similar condition. The exhibitor stated that the main action of the X-rays was to produce a local fibrosis which gradually caused the tuberculous focus to absorb.

Mr. HERBERT W. CARSON showed a specimen of an Extra-Uterine Fœtation which he had removed from a patient, æt. 34. She was almost *in extremis* when admitted to the hospital, the temperature being 101°. At the operation the ruptured tube was found to be adherent to a portion of the small intestine, and, *apropos* of this fact, the operator called attention to recent findings which seemed to indicate that septic organisms played an important part in this class of case. He thought that the presence of the staphylococcus albus, which had been found in quite a number of cases, might help to explain the slight post-operative rises of temperature which frequently occurred in them.

The PRESIDENT exhibited (1) a specimen of Carcinoma of the Body of the Uterus; and (2) one of a Solid Ovarian Tumour.

THERAPEUTICAL SOCIETY.

AT the meeting in the Apothecaries' Hall on October 30th, Dr. T. E. BURTON BROWN, C.I.E., who succeeds SIR LAUDER BRUNTON, Bart., as President of the Society, occupied the chair.

The following papers were read:—

"Some further researches upon the Active Principles of Viola Odorata," by Mr. H. Whippell Gadd, F.I.C., which appeared in our last week's issue; and "The Therapeutical uses of Preparations of Viola Odorata," by Dr. W. A. Potts.

Mr. GADD had carried out many new chemical tests, in the endeavour to demonstrate the presence in violet leaves of the glucoside viola-quercitrin, described by Professor Mandelin. He was sorry to report that his results were entirely negative. He had previously sought in vain for an alkaloid in violet leaves; and now he had searched in vain for a glucoside. He had found varying quantities of glucose in different samples, but could not confirm the presence of viola-quercitrin. The active principle was still quite unknown.

Dr. POTTS showed tracings of the effects of violet preparations upon the pulse, the blood-pressure, and frog's heart. He found very definite depressor effects upon all parts of the circulation; it would therefore be unwise to administer the drug in cases of feeble cardiac power. The action was transient but definite. He had tried the violet preparations both upon himself and upon patients. He found that, after administration by the mouth, the subsequent urine resisted decomposition for many days even in hot weather. He thought this indicated an antiseptic action of some product of the violet preparations in the secretions. This perhaps accounted for the undoubted mitigation of the foulness of discharges from cancers, &c., after the use of the drug. He had also found great relief to pain by local application of violet fomentations, when other means failed. His conclusions were, that violet preparations were most useful (1) locally, for the relief of pain; (2) by the mouth or hypodermically,

for the relief of foul discharges from ulcerating growths; (3) that it was unwise to use them in cases of failing heart.

Dr. Parker Douglas agreed that violet-leaf preparations were of great use in cases which were beyond surgical treatment. They mitigated pain and foulness of discharge, but were not curative.

Dr. Soper, Dr. Crichton, and Dr. Auld joined in the discussion.

Sir Lauder Brunton said he had found violet preparations of great use in the relief of pain and discharge; he said that Dr. Potts' experimental work showed results similar to those obtained with various saponins. The latter had been described by Liebrecht as "anæstheticæ dolcrosæ," in that they produced transient irritation of the skin, followed by anæsthesia. This suggested that violet preparations might be of the greatest use in the treatment of some affections of the eye. He hoped that Mr. Gadd would carry out more researches with the view of testing for saponins in violet leaves. The two papers suggested several lines upon which further experiments might now be undertaken.

Mr. Gadd and Dr. Potts replied. The latter said that violet preparations were being used at one ophthalmic hospital already; but with what results he was not yet able to say.

CENTRAL MIDWIVES BOARD.

Meeting held November 1st, 1906.

The President, Dr. Champneys, in the Chair.

A letter was read by the Secretary from the Clerk of the Denbighshire County Council, forwarding a copy of a resolution passed by the Local Supervising Authority for the County, urging the Board to issue a Welsh translation of the Rules and Forms. The matter was referred to the Standing Committee.

A letter was read also from the Clerk of the London County Council, reporting on the conduct of two certified midwives, to whom the Board expressed satisfaction, and from

Dr. W. H. B. Brook, resigning his position as a recognised teacher under the Rules of the Board. Although he hoped to be able to get together a large class, in all he had had only three applications.

The President regretted that such a good man should resign, and a resolution was passed to ask him to reconsider his decision and to withdraw his application.

The petition to the Board, signed by twelve medical men of Richmond, including the Medical Officer of Health for the town, to reinstate Mrs. Sellwood, L.O.S., was referred to the Standing Committee, as well as a matter dealing with the circulation of circulars by a certified midwife.

THE PROPOSED SECOND STANDARD OF TRAINING.

The Secretary read to the Board a letter from the Secretary of the Queen Victoria's Jubilee Institute for Nurses, embodying a resolution passed by their Council on October 31st, 1906, to the effect that great difficulties would be raised in the working of the Institute by withdrawing the training and supervision of midwives from the Central Midwives Board, that the amendments of the Privy Council suggested, because a large number of the Queen's nurses are drawn from women trained in Poor Law Infirmaries, who hold the Central Midwives' Board certificate, so that the standard of training given in these infirmaries is one that nearly concerns the Institute. Under the proposed amendments, a second standard of training would be established for candidates from Poor Law Infirmaries, and the Board's certificate for such candidates would lose its greatest value. Consequently the employment of these women by the Institute would be limited, entailing thereby an unnecessary hardship on a very desirable class of women. The Council hoped that the Central Midwives Board would not adopt amendments creating a second standard of training.

The President moved that note should be taken of their valuable communication, which was carried unanimously.

The Secretary next drew the attention of the Board to its financial state, and pointed out that the roll had not yet paid its way. The discussion on this subject was adjourned to the next meeting.

The adjourned consideration of recommendation of the Standing Committee, that Local Supervising Authorities, having appointed Inspectors of Midwives, be requested to furnish the Board with copies of the rules that have been drawn up for the Inspectors' guidance, and that where no rules have been compiled, the Local Supervising Authority be asked whether such rules, if drawn up by the Central Midwives' Board, would be acceptable. Owing to the absence of Mr. Fordham, the consideration was adjourned.

The Standing Committee recommended that Dr. J. R. Kaye, County Medical Officer of the West Riding, and Dr. H. Handford, County Medical Officer for Notts, should be thanked for their letters, and assured they should receive the full consideration of the Board. These motions were carried.

The President moved, and Mr. Ward Cousins seconded, a resolution that a copy of the revised rules be sent to Dr. F. J. Smith, Hon. Sec. Metropolitan Counties Branch British Medical Association, and that he be informed that if he will specify in writing any further amendments which the Metropolitan Counties Branch may deem necessary, they will receive the consideration of the Board.

Dr. Parker Young's amendment, that if, after reading the report, Dr. Smith should require further information, the Board will be very pleased to hear from him, was put to the vote and carried.

The President moved, and Miss Paget seconded, the resolution that the application for approval as teacher of Arthur Thompson, M.R.C.S., L.R.C.P., should be granted for the purposes of the December Examination only.

Dr. Parker Young moved, and Sir William Sinclair seconded, in the absence of Mr. Fordham, "that where an application is made by or on behalf of a midwife whose case has been definitely dealt with after citation and a hearing by the Board, for the reconsideration of such case, the Secretary do inform the applicant that the Board are not prepared to re-open cases in which they have given formal judgment, and refer the applicant to the Rules.

Other business dealt with was the subject of examiners. Owing to the death of one of the examiners (Dr. Bell) just before the examination, considerable difficulty was experienced in finding a substitute, and Dr. Lyal, of Newcastle, filled the vacant post.

The Secretary pointed out that three more examiners were needed, one to replace Dr. Bell, and two others to examine the ever-increasing number of students; last week there were 270 candidates.

The President was of opinion that these were posts for rising men, who often were very patient and of much judgment, though it was still too early to advertise yet.

The business concluded with the fixation of the date of the next meeting of the Board for Thursday, November 29th.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 4th, 1906.

THE SURGICAL CONGRESS.

The Surgical Congress, which was held last month at the Paris Faculty, was very well attended. Not only did the questions present particular interest in the *ensemble*, but the communications of Dr. Doyen on his anti-cancer treatment, which last year excited so much unfavourable discussion, were awaited with eagerness, and have already been published.

One of the most interesting papers read was that by Dr. Calot, of Berck-sur-Mer, on the

TREATMENT OF CONGENITAL LUXATION OF THE HIP, AND WHITE SWELLING OF THE KNEE.

The most ardent partisans of the incurability of congenital luxation were obliged to admit themselves vanquished. The method of Calot has been put to the test, and the distinguished surgeon has succeeded in restoring good sound limbs, without shortening or claudication, to children to whom had been applied all kinds of apparatus, and on whom was attempted reduction of the luxation without success.

The details of the treatment have been published in book form by Dr. Calot, which can be had through any medical publisher.

White swelling of the knee was also treated in the Congress by Dr. Calot. He protested with great energy against those operators who cut and fired at will tuberculous joints. Not only did the lesion not get well, but the traumatic interference favoured the absorption of the toxines and the microbes by the blood, which carried the infection. Frequently after the operation the malady broke out further up, or the patient was carried off by meningitis. According to M. Calot, the white swelling got well if the patient lived at the seaside or in the country, if it is not opened or if it is not allowed to open spontaneously.

It gets well leaving the limb in a fair position, but frequently with limited movements.

The treatment consists essentially in modifying injections into the articular cavity, of which the best are composed of a solution of creosote and iodoform in oil. Under their influence the fungosities are softened, become liquid, and can be removed by tapping. Other solutions might be employed, as camphor and guaiacol, salol or thymol; but M. Calot gives the preference to camphorated naphthol, employed in doses of from 2 to 40 drops, according to the age of the subject, injected daily.

When the lesion is in a fair way of healing, the proper function of the limb should be considered. To this end the joint is fixed in plaster apparatus for six months, after which rest of the articulation should be enjoined for another period of six months, and finally massage and passive movement should be prescribed. By these means, the tumour will get well with a normal limb in the majority of cases if treated early; in the others, if the cure is only obtained by a stiff joint, it will be at least in a good position, solid and capable of rendering almost normal service.

M. Delagénière spoke on the

LIGATURE OF THE LARGE VEINS.

He ligatured with success the internal jugular, the axillary, and the femoral veins. M. Duret had practised a large number of sutures of veins successfully. M. Faure thought that it was often better to make a ligature than a suture, which prolonged unnecessarily the operation. Moreover, he had seen air enter the veins in seven or eight cases—once that accident threatened seriously the life of the patient. M. Depage (Brussels) had witnessed the same accident several times, but did not consider it particularly dangerous even when comparatively large quantities of air had penetrated; the alarming symptoms always yielded to artificial respiration.

TREATMENT OF LEUCÆMIA.

IF the different varieties of leucæmia are clinically well known, the cause of the malady is not, consequently there does not exist a rational or specific treatment of leucæmia. However, considerable improvement can be obtained by certain therapeutic agents, which might be divided into three groups—medicines, X-rays, and surgery.

The surgical treatment can only be extended to the extirpation of the hypertrophied glands when they threaten asphyxia by compression of the larynx, or the recurrent nerves.

Splenectomy gave but disastrous results where it was performed.

The best medical agent is arsenic, given in large doses and for a long time. Four or five drops of Fowler's solution should be given the first day, and increased by one drop daily to forty or fifty drops if the patient shows no sign of intolerance.

The employment of the X-rays has given even better results than the arsenical treatment, and may be applied without leaving off the arsenic. They have a destructive effect on the leucocytes.

Radiotherapy is indicated in all the varieties of leucæmia, and, as Belot said at the recent Congress held at Lyons, "a doctor who deprives a patient suffering from leucæmia of this treatment commits a fault as grave as he who does not give mercury for syphilis."

However, it must be said that success is far from being constant.

Acute leucæmia is not modified by radiotherapy, consequently it is only in the chronic form that hope of success can be entertained, and here again a distinction must be made between the rapid form of chronic leucæmia and the slow form, this latter being much more amenable to the treatment.

The rays should be directed on the splenic region, as the spleen is always greatly hypertrophied. One séance a week of a quarter of an hour's duration is considered sufficient, continued for an indefinite period, but with frequent interruptions

Long and important remissions have been obtained by this method, but no absolute cure has been recorded; the fatal termination is alone retarded.

GERMANY.

Berlin, Nov. 4th, 1906

AT the Society for Innere Medizin, Herr Kraus spoke on

GOITRE HEART.

He first discussed the cardiopathies caused by struma and certain affections of the thyroid dependent on disturbances of circulation. Goitre cardiaque was an open question. Stasis goître was of greater significance, which was caused by blocking of the superior vena cava by an ordinary goître. A venous vascular struma might result with a venous pulse, which experience showed gave rise to thyroidism. Blum's experiments justified the whole general opinion that venous disturbances in goitres were factors setting up cardiac affections. According to Kocher's experience, this thyroidism disappeared after operations; by this not only was the disturbance removed but thyroid tissue as well. As regarded the relation, between diseased thyroids and arterio-sclerosis, little could be said with certainty. The most important practically of the cardiopathics caused by diseased thyroid were the mechanical ones; less important those caused by disturbed venous circulation. The dyspnœic goitre heart especially frequently ran its course as a pure progressive cardiopathy, even when certain symptoms of hyperthyriosis (tremor and psychical excitability) were added. This form was very frequent, and called urgently for operation. Cardiac disturbance caused by pressure of the goitre on nerves that influenced the heart had been rarely proved, although several such cases were recorded in literature. This made it desirable to be in possession of diagnostic points for goître thyroidism in distinction from goître cardiopathies. Everything was still very uncertain. Cardiovascular disturbances caused by abnormal functioh of the thyroid were of the greatest interest both theoretically and practically when set up through the medium of nerves regulating the heart, and in the absence of mechanical factors (thyriogenic cardiopathies in the narrower sense). The speaker next

discussed the experimental clinical material at hand for possible thyroid cardiopathies. In any case, cardiac disturbance was here neither the cardinal symptom, nor even a special one. That hypothyroid diseases certainly did not affect the heart was important in an excluding sense for the pathogenesis of Basedow's disease. The symptomatology, statistics, &c., of thyrotoxic goître heart in this sense were discussed at length. For its "Selbständigkeit," a number of reasons were adduced, above all its character as a progressive cardiac disease in which the nervous, trophic, and other symptoms of thyroidism remained rudimentary. The causes for this one-sided, stationary, mitigated condition of the thyrotoxic syndrome in contrast to the typical Basedow type lay in part most probably outside the thyroid.

Herr Senator expressed himself as pleased that Kraus took up the position that the theory that for the origination of Basedow's disease the chief factor was the thyroid gland was not tenable; that something else of importance played a part—the sympathetic. In favour of this view was the fact that Basedow's disease was met with without any enlargement of the thyroid; in any case the enlargement frequently stood in no relation to the severity or mildness of the disease. Some questions still awaited an answer, as whether concomitants of Basedow were present in primary goître, such as diarrhœa or alimentary glycosuria.

Herr Benghardt had directed his attention to the latter point, and had "almost never" observed alimentary glycosuria and diarrhœa in goître heart. Sometimes Basedow and myxœdema symptoms were found together. One patient improved by serum treatment; later symptoms of myxœdema appeared; the earlier cardiac dilatation disappeared; in place of tachycardia there was bradycardia. Improvement had now been achieved by iodothyrine.

LUMBAR PUNCTURE IN ECLAMPSIA.

This subject is treated in a paper in the *Chl. f. Gynæk.*, Oct. 31, 1906, by Dr. E. Pollak. Thiess found the subarachnoid pressure increased. The writer sought to ascertain whether this raised pressure maintained for any considerable length of time had a deleterious effect on the sensitive nerve cells. He found degeneration within the cell bodies to the highest degree of degenerative changetogether with degenerative chromatolysis. Large and numerous vacuoles were visible. An unusually instructive case showed the gravest chromatolysis in the motor cells at the height of the fifth cervical segment. The nuclei also of the oculo motor nerves of the motor trigeminus of the hypoglossal showed changes. He described three cases which were noticeable, as in epilepsy death usually took place through œdema of the lungs, whilst in these it did not. They were cases in which, if the fatal result was not attributable to the puncture, as during the operation no change in the pulse or respiration was observed, yet death did take place if an exacerbation of the symptoms followed the puncture. He was of opinion that the bad result could not be laid to the operation. He thought that the shallow respiration and its gradual standstill were not an immediate result of the puncture, but that the lowered pressure following it did not efface the deleterious effects of the previously raised pressure. Theiss had also described three similar cases.

ABORTION PER RECTUM: RECOVERY.

K. Martin describes such a case in the *Münch. Med. Wochensch.* Oct. 19, 1906. He was called to a woman who had been suffering severe abdominal pain for a week. The uterus was enlarged in correspondence with a five months' pregnancy. To the right a doughy-feeling tumour was felt, and a diagnosis made of inflammation of the cæcum. Ten days after, the patient was found to be very pale, the pulse rapid, the temperature subnormal. Rupture of intestine was suspected. On the following day dark blood was passed per rectum. The pain and feeling of pressure increased, and after several enemata had been given an evacuation took place, consisting of a five months' fœtus, the umbilical cord and placenta. The case was one, therefore, of right-sided abdominal gestation that suppurated and emptied itself through the rectum.

AUSTRIA.

Vienna, Nov. 4th, 1906.

GESELLSCHAFT DER AERZTE.

THE session of this Institute was opened by the President Chrobak offering his greetings to the members, but regretting that so many deaths had occurred since the Institution closed for the summer holidays: in all ten, five honorary and five ordinary. Of the former, Prof. Brouardel, Franz Roser, Tomaselli, Vierordt, and Hermann Cohn; the latter, Profs. Neumann, Czermak, Weinlechner, Modry, and Murmann. The President reminded the members that one of their honorary colleagues would soon reach his seventy-fifth birthday, fifty of which have been spent in the doctorate. He also reminded them of the unveiling of the statue of Semmelweis in Buda-Pesth, a name which will go down to posterity.

The Danish report of the Cancer Committee was now opened to the members in a brochure entitled "Principiis Obsta."

HYDROCEPHALUS.

Hochsinger showed a child, æt. 9 months, with an enormous hydrocephalus, associated with spina bifida in the lumbo-sacral region. There were also manifestations of condylomata in the genito-anal region. According to the history of the parents, the child was born with a normal-sized head, but shortly after birth was affected with coryza with hæmorrhagic discharge which lasted six weeks. About the third week an idiopathic swelling commenced over the sacrum which soon burst and discharged a watery fluid, closing again about the third month. From this date the mother assures us that the head began to swell, but more rapidly the last two months. In the lumbo-sacral region a round fungoid tumour about 5 cms. in diameter still exists. In the labia majora and around the anus as well as the upper part of the thigh are to be found condylomata. The child exhibits symptoms of paralysis and rapid contractions usually associated with hydrocephalus. Hochsinger concluded that the hydrocephalus in this case was due to genuine syphilis producing specific ependymitis, and meningitis serosa, although a myelocystocele might be present. If the former the spina bifida might be assumed to be an hereditary syphilitic development of the whole disturbance.

Zappert thought the water was not due to syphilis, as it is well known that spina bifida when suddenly closed or healed up produces an increase in the cephalic region. No other symptom than condylomata ad anum is present to support the theory of syphilis, which is always present in spina bifida along with the sphincter paralysis and cutaneous anæsthesia. The congestion and thickening of the skin around the anal orifice often produce this imitation of condylomata.

Knopfelmacher said he confirmed Zappert's opinion, as he had a child with an equally large hydrocephalic head under treatment. He had twice performed lumbar puncture, and had relieved the hydrocephalus, which had previously all the symptoms that Hochsinger had demonstrated. By a repetition of the operation the head is diminished to within 1 cm. of its normal size.

TREATMENT OF EPILEPSY.

Redlich gave a *résumé* of a treatment that he recommended in epilepsy, which first of all is diet; and this should be vegetable as far as possible with milk, eggs, butter, and fruit. The food should be free from salt and spices, while all extracts of beef should be avoided, bread containing salts of bromide, which is now sold under the name of "Bromopan," is to be recommended. The medicine should consist of large doses of the bromides daily.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE GENERAL MEDICAL COUNCIL ELECTION.—Dr. Norman Walker opened his election campaign as a candidate for the post of Direct Representative by addressing a meeting in Edinburgh on November 1st. He pointed out that the primary duties of the Council were educational, and on that ground mainly appealed for support. It was easy to sketch the ideal scheme of medical education—easy to say that an Arts degree must be a precursor to medical studies, which might be extended for another year. But they must distinguish between the ideal and the practical. His ideal of a medical education was somewhat on these lines. He would demand a wider preliminary education than at present, and would give a certain elasticity to it, so that it should lead up to a degree either in Arts or Science. Practically, however, they had to deal with the five years' curriculum, and he was convinced that four of these must be devoted to medicine, and that the student should be compelled to pass his first professional before attending any of the classes in the medical curriculum proper. The preliminary examination might very well be stiffened. Five years ago he refused to commit himself to the one portal system, but since then he had become converted, and was now convinced that nothing but good could come of it. The interests of the public, as well as of the profession, required that they should press for legislation concerning patent medicines, requiring that each of these should have its composition printed on the label. He disagreed with those who said that club practice was iniquitous. He asked their support, because he believed his views represented those of the great majority of practitioners in Scotland as to what the duties, responsibilities, and privileges of the profession should be. The meeting was presided over by Dr. G. A. Gibson, and a motion was unanimously adopted welcoming Dr. Walker's candidature. Dr. Frost thereafter read a letter signed by 100 practitioners in Edinburgh favouring Dr. Walker's candidature. In further pursuit of his canvas Dr. Walker will address meetings on November 8th in Aberdeen, and on November 9th in Dundee. Voting papers for the election will be issued on November 24th, and the voting will be completed by December 7th. Dr. Walker contested the seat in 1901, and obtained 854 votes against 975 given to Dr. Bruce, the present representative.

SIR DYCE DUCKWORTH AT THE ROYAL MEDICAL SOCIETY.—The inaugural address of the 170th Session of this Society was given by Sir Dyce Duckworth, who chose as his theme "The Dignity of Medicine." After recalling his connection with the Society in his early days, he said that some educationalists held that the medical curriculum alone afforded a liberal education. From this view he dissented, maintaining that a preliminary study of the humanities was essential to all who aspired to a high place in the medical profession. He was convinced from long experience of the general superiority of those medical students who had enjoyed a good preliminary literary and classical education. No kind of scientific study could in itself supply the place of the Universities, or equally well train the mind. Coming to the topic of his address, he wished to treat of the dignity of the profession of medicine as a whole, as evidenced by its beneficent work as a social power in the community. This particular dignity seemed to him to have declined in recent years, and it rested with them to recover and reconstitute it. The value and benefits of medicine were not adequately recognised by successive British Governments or by municipalities. The timorous, stingy, and inadequate provision made for measures of public health, for the care of the insane, for research, and for sanitation generally, all bore witness to a mistrust of the high aims of medicine, and an indifference to the labours of the profession. How little the public recognised its duty was shown by the fact that it contributed nothing directly, and very little indirectly, towards the maintenance and equipment of any medical school in Great Britain, but was content to leave these bodies to support themselves, and their teachers to forego their emoluments to keep them in a state of efficiency. Everywhere else in Europe their claims were recognised by grants of public money in acknowledgment of the debt due to the beneficence of medicine. The same disregard was shown by municipal authorities in their extortion of rates from hospitals for the suffering poor. Discussions of medical subjects in the public press, so far from enlisting sympathy from intelligent laymen, rather tended to strain the relations between patient and doctor by inducing a captious mood which was apt to hamper successful treatment. The relations of patients to doctors were less satisfactory than formerly; confidence was less, and this not from pretentiousness on the part of the doctor, but only as a part of the spirit of the age. How were they to account for this falling off in the respect in which medicine was held? First, the general modern physician was not a man of such wide learning as formerly. Medicine, ever a jealous mistress, now made such heavy claims on her followers that few could find time or energy to pursue abstract studies or refined scholarship. Science progressed so rapidly that many modern physicians could follow only special departments of practice. Experts were valuable, but they were now witnessing an undue amount of differentiation, and the erection of specialities of doubtful value. Some members, again, failed to commend the profession to the public either by their inflated pretensions, or an inherent inaptitude to adapt themselves to their social environment. Again, anything approaching extortion or greed, or extreme partisanship in political or religious matters, impaired the respect in which medical men should be held, living, as they ought to, in a spirit of comprehensive catholicity and charity. The premature announcement of discoveries and alleged cures was also mischievous. Such abortive results, hurried out of German laboratories for the most part, after occupying attention for a week or two, came to nothing, and yet were reckoned as failures in the field of legitimate medicine. They should try to grow robust in mind, and be level-headed and better fitted to hold their own among members of the other great professions. A vote of thanks was awarded by the gathering, on the motion of the Chairman, seconded by Sir T. R. Fraser, to Sir Dyce Duckworth for his address.

PROPOSED NEW DISPENSARY FOR GLASGOW.—A protest against the erection of the new dispensary, to which reference was made a week or two ago in this column, has been circulated for signature among the practitioners in the district of Anderston. The grounds of the protest are that the neighbourhood is fully supplied by the Western Infirmary, Parish Council Dispensary, and Parochial medical offices, and that there has been no expression of desire that a new dispensary should be erected from the inhabitants of the district.

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH.—The Directors have appointed Dr. J. S. Fowler to be physician to the hospital, *vice* Dr. T. M. Burn Murdoch, who has resigned.

LETTERS TO THE EDITOR.

THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst thanking you for the space previously accorded to me in the discussion of this important subject, I should be glad, in order to prevent confusion, if you will allow me briefly to epitomise my arguments. The force I claim for these, if any there be, is that they are extremely simple, and, moreover, they are impregnable to statistics. Your correspondents will observe that I readily admit decadence of the

British nation is now taking place; further, that it must inevitably continue so long as we build up an insecure Empire at the expense of the British nation, which emigration implies; indeed, to quote Lord Avebury, as reported in yesterday's *Daily Telegraph*, emigration would take away the best of our working classes, leaving the loafer, the less industrious, and the least energetic at home. Your correspondents will further observe that what I join issue upon is that a declining birth-rate, although it may be indicative of deeply seated evils, is in no degree responsible for the decadance. On the contrary, the decline affords us a valuable opportunity of setting our house in order if only we avail ourselves of it. On the other hand, what could be more prejudicial to the health and prosperity of our nation than an enormously increasing surplus population, thereby adding fuel to the fire. Mr. Lloyd-George tells us "there are ten millions in this country enduring year after year the torture of living on, or lacking a sufficiency of the bare necessaries of life." Sir Henry Campbell-Bannerman also tells us "there are twelve millions of people in this country living on the verge of starvation." Now, it is obvious that any increase of progeny amongst these would intensify the melancholy condition of things existent. On the other hand, an increase amongst the already overburdened middle-class must compel these either to join in the emancipation scheme (it could not reduce the 10 or 12 millions just referred to), or to rapidly degenerate from want of adequate means to sustain a healthy environment.

I am, Sir, your truly,
CLEMENT H. SERS.

Brighton, November 3rd, 1906.

VIOLET LEAVES AND CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I fear that the article on this subject in your current issue may lead to some misapprehension. It is true that, after many months of work, I have been unable to isolate any definite chemical principle from violet leaves, although I have obtained very strong evidence of the presence of a glucoside. But a paper read by Dr. W. A. Potts, of the Birmingham University, at the recent meeting of the Therapeutical Society in London, conclusively proves, I think, that although there is no ground for the extravagant hopes which have been raised as to the leaves proving curative in cases of cancer, they have, undoubtedly, therapeutic activity, particularly of an anodyne and antiseptic nature. At the same time, as Dr. Potts has shown, the very activity of the leaves constitutes a danger when they are used by unskilled persons, their administration being contra-indicated in patients with feeble hearts.

I am, Sir, yours truly,
H. WHIPPELL GADD.

Exeter, November 5th.

THE GREAT ORMOND STREET HOSPITAL FOR SICK CHILDREN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Those who know London well would probably agree that the district which lies around Great Ormond Street is the most crowded and trying for the children of those who live in it. At one time the Seven Dials district was perhaps worse; but the great changes that have been carried on of late in the West Central parts are clearing away the unhealthy courts and alleys where the poor children were being reared by a class of parents far less capable than those that live and work in the parts lying far away in the East of London.

The question that the Duke of Fife's letter to *The Times* suggests is whether the ills arising from bad sanitation and high temperature can possibly be much relieved by the crowded treatment of a hospital out-patient department, for the maladies are not such that much good can be done by a special ward and a few admissions into it. If the object of this hospital is to provide for the neighbourhood in which it stands, it would be better to make a great change in the mode in which the work has been carried on for many years, and remove the chronic and surgical cases to a better atmosphere and healthier surroundings. That kind of work which the Duke of Fife considers proper for the Children's Hospital would be far better done on the old dispensary system, and it would be well for those interested in the hospital to watch carefully the dangers that may arise in the spread of infectious disease by crowding large numbers of out-patients suffering from contagious and infectious diseases in the waiting rooms.

I am, Sir, yours truly,
OBSERVER.

London, November 5th, 1906.

OBITUARY.

F. W. NEWCOMBE, J.P., M.D., M.S.DURH.

WE regret to announce the death of Dr. Frederick W. Newcombe, J.P., of Gateshead, which took place on October 26th, after a brief illness. Dr. Newcombe was educated at Durham University and the Newcastle College of Medicine. He took the degrees of Doctor of Medicine and Master in Surgery at Durham University, winning also the University Scholarship, and Medals in Medicine and Surgery. He commenced practice in Gateshead, which continued to be the place of his residence for the remainder of his life. Dr. Newcombe was a popular medical man, and built up a large practice. He was also an honorary physician to the Dispensary and medical officer of the Abbot Memorial School, and a certifying surgeon under the Factory Act. Some ten years ago he was appointed a Justice of the Peace for Gateshead.

LEWIS SMYTHE, M.R.C.S., L.S.A., M.D.GLAS.

WE regret to announce the death of Dr. Lewis Smythe at his residence Lewes, in his 88th year. Born at Dublin, the deceased gentleman took his degree as Doctor of Medicine at Glasgow University as early as 1840. He took his M.R.C.S. the previous year, being elected Fellow in 1861. In 1852 he qualified for L.S.A. London. He came to Lewes about sixty years ago. Owing to advancing years Dr. Smythe retired in 1893. For many years he acted as surgeon to the East Sussex Constabulary at Lewes, but he relinquished this office twelve years ago, and was succeeded by Mr. Fawssett.

SAMUEL AIRD JOLLY, L.R.C.S., L.R.C.P., ED., L.F.P.S., GLASGOW.

DR. S. AIRD JOLLY, whose death occurred last week at his residence, Acton, had been for many years medical officer to the Brentford Board of Guardians, and was also one of the honorary medical staff of the Acton Cottage Hospital. He took the diploma of the Edinburgh Colleges in 1876, and later became L.S.A. London.

SPECIAL ARTICLE.

A SIDELIGHT ON MEDICAL EDUCATION.

As our readers are aware, articles under the above title have been appearing at intervals for some years back in the columns of the *British Medical Journal*. These articles were based on the figures of rejections and successes at the examinations for admission to the various medical services—Navy, Army and Indian, and their avowed intention was to throw "a sidelight upon the educational methods and curricula in force in different parts of the United Kingdom." (*Brit. Med. Journ.*, Jan. 7th, 1905). Attention, it was claimed, was drawn "to the valuable light which an analysis of a sufficient number of them might be made to throw upon the efficiency of the different methods of tuition in vogue in different parts of the Kingdom, as gauged by the success of candidates who held respectively either English, Scottish, or Irish diplomas or degrees." (*Brit. Med. Journ.*, Dec. 3rd, 1904).

We have ourselves, in commenting from time to time on these articles, pointed out the many fallacies which underlie such an argument as that suggested in the last sentence. One has no right to assume that the candidates coming from the different schools are equally fairly representative of their schools, and, indeed, there are strong indications to believe that they are not. The tables as quoted give us no information as to the ages of the candidates, or as to the way in which they have spent their time in the interval between obtaining their diplomas and presenting themselves for the service examinations. The examinations, moreover, are, or have been till lately, London examinations, a point to which we shall presently return.

In spite of the admission that results must be based on "an analysis of a sufficient number," we find over and over again conclusions drawn from an absurdly inadequate number of figures. Thus, to take the first example at hand (Table VII., Supplement to *Brit. Med. Journ.*, June 2nd, 1906), we find that eight groups of candidates are each credited with 100 per cent. qualified, but on looking at the actual numbers of candidates on which the percentages are estimated, we find them to vary from 52 for the English Conjoint Board to 1 for Birmingham University!

The tables of our contemporary have, therefore, appeared to us vitiated both by their structure and by the assumptions on which they were based, and we have never troubled to analyse them with care. Professor Dixon, of Dublin, has taken this trouble, and some of the results are, as he mildly puts it, "remarkable." His communication, with the editorial comments thereon, appear in the *British Medical Journal* of the 27th ult. Not only are the conclusions vitiated in the way we have pointed out, but the tables show glaring and gross inaccuracies. In the analyses published on June 3rd, 1905, the average proportion of success to candidates is given in three different tables as 33.9, 54, and 47.8 respectively. All these figures are wrong. In fact, in Tables IV., V., VI., VII., VIII. of this date, the average given at the bottom in each case is wrong. The mistake apparently arose because the compiler, to obtain a gross average, added together a number of independent averages and then divided the result by the number of averages so treated. The mistake in some cases is so great as between 64.8 and 81. This is the more notable in that it is inconsistent with the results obtained in another way by the same compiler, and given in the same series of tables. The other tables are not more trustworthy.

One would have expected some answer to Dr. Dixon's criticisms, but the editor airily remarks that they "in nowise really affect the essential structure of the tables," and that "conceivably they are well founded, conceivably they are otherwise; but in any case it is scarcely worth while to devote time and space to their consideration." Now, figures are either right or wrong; in mathematics there are not two sides to any question. If the figures in the *British Medical Journal* are correct they should be defended; if not they should be withdrawn. As it is, certain conclusions have been based on figures alleged to be inaccurate, and instead of admitting an error, the *British Medical Journal* claims that the conclusions stand even if the figures fall.

We mentioned above that the Service examinations are, or have been, London examinations, and that thereby provincial, Irish and Scottish candidates are, or were, at a certain disadvantage. Professor Dixon has also raised this point, but he shows that whereas some years ago London carried off by far the largest proportion of successes, nowadays, as the requirements of the examinations are becoming more widely understood, and, we may add, as examiners are chosen from a wider area, successes are becoming more evenly distributed. The *British Medical Journal*, however, sees something "unpleasant" in this suggestion. Nevertheless, there is no imputation of unfairness to anyone in stating the obvious fact that a candidate examined by his own teachers, possibly on clinical cases he has already seen, has certain advantages over a candidate from a distance. To quote the *present* list of examiners in reply to this suggestion is somewhat evasive, as the inequality in results between the London school and others is fast disappearing. Even taking the present list, however, London has an undue preponderance of examiners, in proportion to the number of candidates from each school. The list, as quoted in our contemporary, consists of the names of three London gentlemen, and of one each from Cambridge, Dublin, Edinburgh, Belfast, and Aberdeen.

BELFAST.

CONSUMPTION IN COUNTY ANTRIM.—A meeting was held last week in Ballymena, to consider the question of the erection of a sanatorium for consumptives for County Antrim. Delegates attended from Ballymena and Larne Urban Councils, and Ballymena, Antrim, and Larne Rural Councils. Dr. Clibborn, medical inspector of the Local Government Board, was also present. A resolution in favour of the erection of a sanatorium was passed unanimously, and a committee appointed.

THE HEALTH OFFICER AND THE CITY COUNCIL.—At the monthly meeting of the Belfast Corporation last week, the recent appointment of Dr. Bailie as medical officer of health was again under discussion, one of the members of the Council asking for the production of a letter said to have been received from the Local Government Board. The Chairman of the Public Health Committee, Dr. King-Kerr, did his best to keep the letter dark, and even professed ignorance of its contents, saying he had not heard it read. His absurd efforts were ably seconded by his clique, with the result that the Corporation refused to order the production of the letter. Naturally this gave the widest publicity to the fact that something was being kept secret, and to the delight of the city the letter, dated October 11, was published in full in the *Northern Whig* on Friday last. It is a scathing condemnation of the job perpetrated by the Corporation, and must be most galling to those who put Dr. Bailie in office, more especially as they know the citizens generally agree with every word of it. But the idea that such a letter could be successfully suppressed speaks volumes for the mental powers of these gentlemen on the Corporation. One correspondent in a daily paper remarks that the only reason he can attribute to Dr. King-Kerr for his action in the matter is a wish on his part to be in the fashion in possessing "embarrassing letters"!

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of last list:—

JOHN BALE, SONS, AND DANIELSSON, LTD. (London.).

A Few Hints on the Care of Children at Sea. By Samuel Synge, M.A., M.D., &c., &c. Pp. 30. Price 1s. net.

Pulmonary Phthisis: Its Diagnosis, Prognosis, and Treatment. By H. Hyslop Thomson, M.D. Pp. 188. Price 5s. net.

BAILLIERE, TINDALL AND COX (London).

The Nature and Treatment of Cancer. By John A. Shaw-Mackenzie M.D.Lond. Fourth Edition, revised. Pp. 107. Price 2s. 6d net.

On Retro Peritoneal Hernia: Being the "Arris and Gale" Lectures on the Anatomy and Surgery of the Peritoneal Fossa, delivered at the Royal College of Surgeons of England in 1897, by B. G. A. Moynihan, M.S., F.R.C.S. Second Edition, revised and in part re-written, by the author and J. F. Dobson, M.S., F.R.C.S. Illustrated. Pp. 195. Price 7s. 6d. net.

The Use of X-Rays in General Practice. By R. Higham Cooper, L.S.A. Illustrated. Pp. 98. Price 2s. 6d. net.

High Frequency Currents. By H. Evelyn Crook, M.D., B.S.Lond., F.R.C.S.Eng. Illustrated. Pp. 206. Price 7s. 6d. net.

Lectures on Diseases of the Lungs. By James Alexander Lindsay, M.D., F.R.C.P.Lond., M.A. Second Edition, enlarged and re-written. Pp. 509. Price 10s. 6d. net.

Syphilology and Venereal Disease. By C. F. Marshall, M.D., M.Sc., F.R.C.S. With 5 plates. Pp. 509. Price 10s. 6d. net.

Minor Maladies and their Treatment. By Leonard Williams, M.D., M.R.C.P. Pp. 383. Price 5s. net.

The Sigmoidoscope: A Clinical Handbook on the Examination of the Rectum and Pelvic Colon. By P. Lockart Mummery, B.C. Cantab., F.R.C.S.Eng. Pp. 88. Price 3s. 6d. net.

Transactions of the Medico-Legal Society for the Year 1905-1906. Edited by R. Henslowe Wellington and Stanley B. Atkinson, M.A., M.B. Vol. III. Pp. 122. Price 7s. 6d. net.

William Blackwood and Sons (Edinburgh).
The $CHCl_3$. Problem. By Richard Gill, B.Sc., &c., &c. Price, 2 vols., 10s. net.

Cassell and Co., Ltd. (London).
Submucous Excision of Deviations and Spurs of the Nasal Septum. By St. Clair Thomson, M.D., F.R.C.P., F.R.C.S. Pp. 48. Price, 1s. net.
The Health Reader. By W. Hoskyns Abrahall, with an Introduction by Sir Victor Horsley, F.R.S., F.R.C.S. Illustrated. Pp. 277.

Darling and Sons, Ltd. (London).
Thirty-fourth Annual Report of the Local Government Board, 1904-1905. Supplement containing the Report of the Medical Officer for 1904-1905. Pp. 428. Price 4s.

Davos Printing Co., Ltd. (Davos).
Davos as Health-Resort: A Handbook, with Introduction by W. R. Huggard, M.A., M.D. Illustrated. Pp. 316.

George Gill and Sons, Ltd. (London).
Nursing at Home. By J. D. E. Mortimer, M.B., and R. J. Collie, M.D. Pp. 128. Price 1s. 6d. net.

Henry J. Glaisher (London).
Clinical Lectures on Neurasthenia. By Thomas D. Savill, M.D. Lond. Third Edition, revised and enlarged. Pp. 216. Price 7s. 6d. net.

Charles Griffin and Co., Ltd. (London).
Outlines of the Diseases of Women. By John Phillips, M.A., M.D., &c. Illustrated. Fourth Edition, revised and enlarged. Pp. 282. Price 7s. 6d.

J. Jacobs (London).
Hypnotism and Suggestion. By Edwin Ash, M.B., B.S.Lond. M.R.C.S.Eng. Pp. 136. Price 4s. net.

H. K. Lewis (London).
Medical Electricity: A Practical Handbook for Students and Practitioners. By H. Lewis Jones, M.A., M.D. Fifth Edition. Illustrated. Pp. 519. Price 12s. 6d. net.
The Röntgen Rays in the Diagnosis of Diseases of the Chest. By H. Walsham, M.A., M.D., and C. Harrison Orton, M.A., M.D., Illustrated. Pp. 80. Price 6s. net.
Æquanimitas: With Other Addresses to Medical Students, Nurses, and Practitioners of Medicine. By William Osler, M.D., F.R.S. Second Edition. Pp. 475. Price 8s.
Refraction of the Eye. By A. Stanford Morton, M.B., F.R.C.S.Eng. Seventh Edition. Pp. 96. Price 3s. 6d.
Elements of Practical Medicine. By Alfred H. Carter, M.D., M.Sc. Ninth Edition. Pp. 614. Price 10s. 6d.

Longmans, Green and Co. (London).
Helouan: An Egyptian Health Resort, and How to Reach It. By H. Overton Hobson, M.D.Edin. Illustrated, and two maps. Pp. 88. Price 2s. 6d. net.

Macmillan and Co., Ltd. (London).
Collected Papers on Circulation and Respiration. First Series. By Sir Lauder Brunton, M.D., &c., &c. Pp. 696. Price 7s. 6d. net.

Methuen and Co. (London).
The Hygiene of Mind. By T. S. Clouston, M.D., F.R.S.E. Illustrated. Pp. 284. Price 7s. 6d. net.

James Nisbet and Co., Ltd. (London).
Experiments on Animals. By Stephen Paget, with an Introduction by Lord Lister. Third and Revised Edition. Pp. 387. Price 4s. 6d. net
Alcoholism: A Chapter in Social Pathology. By W. C. Sullivan, M.D. Pp. 214. Price 3s. 6d. net.

Rebman, Ltd. (London).
The Diseases of Women: A Handbook for Students and Practitioners. By J. Bland-Sutton, F.R.C.S.Eng. and Arthur E. Giles, M.D., B.Sc.Lond., F.R.C.S.Edin. Fifth Edition. Illustrated, Pp. 536. Price 11s. net.
The Development of the Human Body. By J. Playfair McMurrich, A.M., Ph.D. Second Edition, revised and enlarged. Illustrated. Pp. 539 Price 14s. net.
The Influence of the Menstrual Function on Certain Diseases of the Skin. By L. Duncan Bulkley, A.M., M.D. Pp. 108. Price 5s. net.
Hypnotism; or, Suggestion and Psychotherapy. By Dr. August Forel. Translated from Fifth German Edition by H. W. Armit, M.R.C.S., L.R.C.P. Pp. 370. Price 7s. 6d. net.

The Walter Scott Publishing Co., Ltd. (London).
Race Culture or Race Suicide: A Plea for the Unborn. By Robert Reid Rentoul, M.D., &c., &c. Pp. 182. Price 7s. 6d. net.

The Scientific Press, Ltd. (London).
Notes on General Practice. By S. M. Hebblethwaite, M.D. Pp. 78. Price 3s. 6d. net.

W. B. Saunders and Co. (London).
The Illustrated Medical Dictionary. By W A. Newman Dorland, A.M., M.D. Fourth Edition revised and enlarged. Pp. 836. Price 19s. net.

Smith, Elder and Co. (London).
Artificial Feeding of Infants. By W. B. Cheadle, M.D.Cantab., F.R.C.P. Sixth Edition, revised by F. J. Poynton, M.D.Lond., F.R.C.P.
Auscultation and Percussion, together with the other Methods of Physical Examination of the Chest. By Samuel Gee, M.D. Fifth Edition. Pp. 325. Price 6s.

Sudan Government, Dept. of Education. (Khartoum.)
Second Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By Andrew Balfour, M.D., B.Sc., &c., &c. Pp. 255

John Wright and Co. (Bristol).
Golden Rules of Medical Evidence. By Stanley B. Atkinson, M.A., M.B., &c. Pp. 63. Price 1s.
A Guide to Urine Testing for Nurses. By Mark Robinson, L.R.C.P., L.R.C.S.Edin. Third Edition, revised. Pp. 56. Price 1s. net.
Lectures on Massage and Electricity in the Treatment of Disease. By T. S. Dowse, M.D., &c. Sixth Edition, revised. Pp. 447 Price 7s. 6d. net.
Woman's Health and How to Take Care of It. By Florence Stackpoole. Second Edition, revised. Pp. 165. Price 1s. 6d. boards, 2s. 6d. cloth.

Edward Arnold (London).
The Diagnosis of Nervous Diseases. By Purves Stewart, M.A., M.D., F.R.C.P. Illustrated. Pp. 380. Price 15s. net.

REVIEWS OF BOOKS.

CLINICAL STUDIES OF NUTRITIONAL DISORDERS (*a*)

This small work forms a valuable supplement to the volume entitled "Nutrition of the Infant," by the same author, which was favourably reviewed in these columns in the autumn of 1904. The writer is well known as an enthusiastic worker on infant-feeding. The book before us gives abstracts of a number of typical cases of malnutrition which have been under Dr. Vincent's care at the Infants' Hospital. The plan adopted is to give a very brief history of each case, and then a full account of the milk or other mixture on which the patient was fed, together with notes on the infant's after-progress. The milk mixtures are given in percentages of their ingredients—namely, fat, lactose, whey-proteids, and caseinogen, while the degree of alkalinity is always noted. A careful perusal of these case-histories is very instructive, and although no rule-of-thumb method can be followed in infant-feeding, still, by following the author's methods the practitioner will be better equipped for the management of difficult cases which constantly present themselves for treatment in daily practice. Infant-feeding has a real scientific basis, and Dr. Vincent is a strong adherent to the method of percentage feeding. His results are excellent, and he must accordingly be congratulated thereon. His book is of great interest and importance, and is well worthy a place in the list of really useful treatises on the subject of infant-feeding. It is well-arranged, nicely printed, and neatly bound.

THE PROLONGATION OF LIFE. (*b*)

The longing for life and the dread of death are almost natural characteristics of the young and vigorous. But with advancing years physical enfeeblement, mental limitation, and lack of the powers on which depend the ability to make ready adjustments, old age is only too apt to become wearisome, querulous, and oftentimes burdensome. The art of prolonging life to a joyous and serviceable eventide needs to be cultivated. It is little wonder that the charming lecture published in this attractive volume should have found such favour as to call for a second edition. It is written by one who, having borne the heat and burden of the day, now views the long road with the satisfaction of a journey well travelled and a rest rightly won. Sir Hermann writes with the charm and experience of the philosophic physician who has blended science with human sympathy. The book is one to be studied by the aged, but it is full of lessons for the young. Every physician should read it, and any intelligent layman may study it with advantage. It is a guide to pure living, high thinking, and rational regulation of life's duties and pleasures. The author tells us that in his analysis of the records of more than one hundred cases of long-lived persons, he found that "by far the majority of them were temperate; were small meat eaters; lived much in the open air; led an active life; many, a life of toil with great restrictions as to food and comforts; that most of them were early risers; that a great number of them had a joyful disposition, and performed their work cheerfully; and that only a few were intemperate or idle and lazy persons."

(*a*) "Clinical Studies in the Treatment of the Nutritional Disorders of Infancy." By Ralph Vincent, M.D., F.R.C.P., Physician to the Infants' Hospital. London: Baillière, Tindall, and Cox. 1906. 3s. 6d. net.

(*b*) "On Means for the Prolongation of Life." Second and enlarged edition of a Lecture delivered before the Royal College of Physicians on December 3rd, 1903. By Sir Hermann Weber, M.D., F.R.C.S. Pp. 104. London: John Bale, Sons and Danielsson, Ltd. 1906.

MEDICAL NEWS IN BRIEF.

A Leeds Home.—Bodies alleged to have been burnt.

STARTLING evidence as to the real character of a "maternity home" in Leeds, was heard last week, when serious charges were made against Elizabeth Miller (45), a Leeds nurse, who had controlled the home.

A single woman, living in Leeds, stated that in response to an advertisement she saw the accused on September 25th. Witness had told Miller of her condition in a letter prior to the interview. On the occasion of the interview the prisoner said: "What I am going to tell you is strictly private and confidential between ourselves."

Mr. Atter: Were any terms mentioned between you and her?

Mr. Atter: She said if I could get a certain sum for her she could do something for me.

His Worship: Did she mention the sum?

Witness: Yes, £15.

Witness was unable to find the money and left.

A widow named Phyllis Hibbert then entered the witness box, and spoke to having been under the treatment of the prisoner, whom she first saw on September 6th last. Miller remarked to her at the initial interview that if she would pay £10 there would be no need to go to the end.

Witness went to live in the house and Miller gave her some brown liquid in a cup, and also some pills.

Mr. Atter: Did she say what would happen to anybody if anything was said?

Witness: She said if I repeated what she had said or had done, she would get ten years, and I should get five.

Mr. Atter: Did she say anything else?

Witness: She said, "You know I have a doctor behind me."

Mr. Atter then intimated that he was going to call a witness who would speak as to the way in which the bodies had been disposed of. "I shall be able to prove," said Mr. Atter, "if this evidence is admissible, that a number of bodies have been disposed of by burning."

A woman named Annie Farrar stated that fifteen months ago the form of a child was put under the copper.

Who put it under the copper?—Nurse Miller.

Where did the child come from?—Out of the bedroom.

Dr. Alexander B. S. Stewart, of Woodhouse Square, stated that on Sunday a fortnight ago he saw the prisoner, and he told her that he had had a woman down to see him, who said that she had paid the prisoner £15, ten of which were for witness's fee, Nurse Miller said the £15 was for lodgings, and she flatly denied that she had said that £10 was for witness.

He had never received £10 for attending on any of the patients at the home. The biggest fee he ever got from the prisoner was £3. He looked upon the home as a proper maternity home, and saw nothing improper about it. He had been summoned there in certain cases.

The further hearing was adjourned until Wednesday next.

Christian Science.

AT Acton, Robert F. Chisholm, 69, an architect, of Bedford Park, was charged on a warrant with feloniously killing his son, William M. Chisholm, æt. 10, by wilfully neglecting him.

Mr. Gill said the Christian Scientists objected to medical aid. The boy became ill at school, and on taking to his bed a "healer" was called in, but the boy died from diphtheria. The decisions on the point were to the effect that if a man neglected to do certain things in consequence of which his child's death was accelerated, he was guilty of manslaughter. He submitted that though Christian Scientists might be entitled to carry out their ideas upon themselves, they ought not to be allowed to practise upon those too young to judge for themselves.

Dr. Bishop, Acton, stated that he was summoned to the house of the prisoner, who said his son was dead, and that he thought it was a case of mumps. Witness examined the body of the boy, and, being satisfied that death had occurred, communicated with the coroner. Witness then proceeded to state the condition of the body, and the symptoms which pointed, in his opinion, to a case of diphtheria. If the deceased had been properly treated his chances of recovery would have increased. The fact that he lived twelve days showed that he had good vitality and strength.

Evidence given before the coroner showed that Miss Turner, the "healer," suggested that a doctor might be called in, as Mrs. Eddy, the head of the sect, had advised this in infectious cases.

A remand was ordered.

A Medical Man charged with Murder.

A GREY-HAIRED man of fifty-seven, named Arthur Raynor, described as a physician and surgeon, of 83, Palmerston Road, Kilburn, appeared last week at Marylebone, charged with the wilful murder of Anne Lillian Martin, a young married woman, æt. 32, living at Kentish Town.

The accused, who appeared to be suffering from partial paralysis, was assisted into court and allowed to remain seated during the hearing.

Detective Inspector Neil described how he found Raynor the previous evening in the back basement room of 83, Palmerston Road. He explained that prior to her death Mrs. Martin made a statement before a magistrate as to the treatment she had received at the hands of the accused, and that he had performed a certain operation. The accused was also told that two doctors had stated that the woman died from septic poisoning. An instrument was found in the room, but the accused said that he used it for a perfectly innocent purpose.

Raynor was remanded in custody.

Opening of Committee on Industrial Diseases.

A departmental committee was recently appointed to "inquire and report what diseases and injuries, other than injuries by accident, are due to industrial occupations, are distinguishable as such, and can properly be added to the diseases enumerated in the Third Schedule of the Workmen's Compensation Bill, 1906." The work thus outlined is of great importance, and includes the investigation of the following diseases and injuries, viz.: gradual poisoning from the vapour of carbon disulphide, dinitrobenzol, dinitrotoluol, and anilin; gradual poisoning from carbonic oxide gas, sulphuretted hydrogen gas, and chlorine gas; alkaloidal poisoning from African boxwood in shuttlemaking; illness set up by nitrous fumes, hydrochloric acid fumes, ammonium chloride fumes, and sulphur fumes; compressed air illness (caisson disease); chrome ulceration of the skin; various trade eczemas; fibrosis of the lungs from inhalation of silicious or metallic particles (potter's asthma and grinder's phthisis); pneumonia from inhalation of basic slag dust; miners' nystagmus and miner's "beat knee" and "beat hand"; neurosis due to vibration; cardiac dilatation in slate quarries; and glanders. Correspondence relating to the inquiry should be addressed to Frank Elliott, Esq.

secretary to the committee, at the Home Office, Whitehall, S.W. Anthrax, ankylostomiasis, and poisoning by lead, mercury, phosphorus, and arsenic are already included in the Third Schedule of the Workmen's Compensation Bill, and are not, therefore, within the Committee's terms of reference.

Scabies in relation to Blankets and Sleeping Suits for Soldiers.

THE following letter from *The Broad Arrow* is of much suggestive significance, especially in view of a recent notorious "ragging" case:—

"SLEEPING SUITS FOR SOLDIERS.

"Sir,—I think very few sensible people will disagree with Surgeon-General Evatt in his views as to the provision of sleeping suits for soldiers. There can be no question as to their usefulness from a sanitary standpoint. At the same time, one wonders why he has thought it necessary to insinuate that itch amongst soldiers is produced and propagated by means of army blankets. I think there is not much doubt that itch is usually picked up outside barracks, and it very often happens that some form of venereal disease is contracted at the same time. An examination of medical history sheets, of men who have had some years' service, will usually show several entries for venereal disease and an occasional one for itch. The disease is usually found either amongst newly-joined recruits, or in men who have just returned off furlough. The men are sent to hospital with their 'filthy blankets' and the whole of their clothing. The latter is put through the hospital disinfector, and the men are treated. That ends the trouble. Non-commissioned officers in charge of rooms are more intelligent than they used to be, and the men themselves are quite averse to allowing anyone with any skin disease to remain in their midst. Men returning off furlough are inspected with a view to detecting this disease. Weekly sanitary inspections also serve the same purpose. Itch is not by any means the prevalent disease in army life nowadays that one would be led to expect by reading Surgeon-General Evatt's letter. In this garrison there have been up to the end of October thirty-nine cases. The average strength has been about 3,500. As regards treatment by sulphur, I think that as soon as it becomes generally known what the powers of balsam of Peru are, when applied to the skin of itch cases, the former remedy will cease to be used.—I am, etc.,"

F. J. W. PORTER (Major), R.A.M.C.

Colchester, October 29th.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, was held on October 26th. There were present—Dr. de Havilland-Hall, in the chair, Dr. J. Brindley James, Dr. J. W. Hunt, Dr. F. S. Palmer, Dr. Walter Smith, Dr. St. Clair, B. Shadwell, Dr. F. J. Allan, Dr. H. A. Sansom, Mr. J. F. Colyer, and Dr. J. B. Ball. The Society has had a moderate Sick Claim List during the summer months, and has added an appreciable amount to its already large reserves. The number of new entrants has been more than the average, but the Committee appeal to the members to bring under the notice of their medical friends the many advantages obtained by those who join the Society. In this way the useful work which it is doing could be largely extended. Prospectuses and all other particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London.

Royal University of Ireland.

THE Senate of the Royal University have adopted the following resolution:—"That in the judgment of the Senate of the Royal University, it would be disastrous to the interests of education in Ireland, and gravely injurious to the welfare of the country, to concentrate the control of higher education in one University."

Irish Medical Association.

WE regret to hear that Dr. Leonard Kidd, of Enniskillen, has resigned his membership of the Irish Medical Association. We trust that we have been misinformed, as the resignation of such men is fraught with the gravest danger to the Association.

PASS LIST.

Royal College of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on October 31st, with the following results:—

First Examination, Five Years' Course.—Of 28 candidates entered, the following eight passed the examination: Bhairawnath Dinanath Khote, Bombay; Robert Eric Noel Martyn Clark, Punjab; Andrew Dawson Turnbull, Edinburgh; William James Moore, Dunoon; Alexander Fitchie Taylor, Fraserburgh; John Adami, Malta; William James Hogg, Birmingham; and Harry Russell Macnab, Downpatrick; and one passed in Physics, four in Biology, and one in Chemistry.

Second Examination, Four Years' Course.—Of two candidates entered, the following one passed the examination: George Vernon Edwardes, Cheshire.

Second Examination, Five Years' Course.—Of 26 candidates entered, the following 13 passed the examination: George Francis Hegarty, Cork; Cornelius O'Herlihy, Cork; James Thomas Gwynne Jones, Wales; Zerk Daniel Lotter-Luther, Cape Colony; Charles William Gee, Wigan; Sydney Granville Tibbles, Nottingham; Reginald Andrew Hosegood, Swinton; George FitzWilliam Forde, Ballygeany; Evan Aynsley Klein, British Guiana; Denis Michael O'Sullivan, Ireland; William Clair Leonard Malone, Australia; Karl Frederick Percy Richard Gover, British Guiana; and George Noel Braham, Bath; and one passed in Anatomy, and one in Physiology.

Third Examination, Five Years' Course.—Of 29 candidates entered, the following 12 passed the examination: Eduljee Perozshaw Meherjee, Bombay; Maria Shepherd Allen, Cheadle; Augustus Jourdain Kelsey, Mauritius; Zerk Daniel Lotter-Luther, Cape Colony; Alexander McMurray, Belfast; Hugh Clement de Souza, Rangoon; William Henderson, Scotland; Joseph Louis Pinto, Portuguese India; Frank Humphrey Kiddle, India; Andrew Downie Macfie, Scotland; Edward Lewis, Anglesey; and Francis Wardlaw Milne, Helensburgh; and three passed in Pathology and two in Materia Medica.

Final Examination.—Of 82 candidates entered, the following 30 passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P.&S.G.: Walter Bingham Kendall, Canada; Neil McLeod, Edinburgh; Charles Edward Preston, Canada; Lionel Langford Westrope, Shrewsbury; John Henry Morris Jones, N. Wales; Henry James Gorrie, Dundee; Merwanji Dinshah Printer, Bombay; Zilla Edith Da Costa, India; Henry Fleet Gordon, Canada; Dhunbai Maneckji Cama, India; Harold Lyons Hunt, Canada; Harry Ferguson Shepherd, Lisburn; Henry Ruddock Morehead, Co. Cork; John Clarke, Ballymena; Satya Charan Pal, Bengal; Emma Irwin, New Zealand; Thomas Mayne Reid Waddell, Tokio; Walter Hugh Pearless, Victoria; Tandalam Madhava Row, Kumbakonum; Lizzie Lyford de la Harpe, Ceylon; Percy Bateman, Cork; Robert Thomas Aloysius Patchett, Lancashire; Eduljie Perozshaw Meherjie, Bombay; David Graham Barkley, Edinburgh; Capel Geary Dyer, Hampshire; Richard Baring Davidson, Congleton; Munchersha Byramji Irani, Bombay; James Augustus Robertson, British Guiana; Arthur Donald Roberts, India; and John Henry Peter Wijesinghe Ceylon; and 16 passed in Medicine and Therapeutics, 3 in Surgery and Surgical Anatomy; 17 in Midwifery; and 13 in Medical Jurisprudence.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Ascites as a Prognostic Factor in Alcoholic Cirrhosis of the Liver.—Ramsbottom (*The Med. Chronicle*, October, 1906) discusses the significance of this symptom in the prognosis of alcoholic cirrhosis. His investigation is based on 68 fatal cases of alcoholic cirrhosis of the liver, and simple peritonitis, met with in the Manchester Royal Infirmary during the last twenty years, upon which post-mortem examinations were made. Fourteen years ago Hale White, in a paper on this subject, claimed that ascites is of the gravest prognostic significance in that type of cirrhosis of the liver usually ascribed to alcohol, in that when once ascites appears, unless some degree of chronic peritonitis exists, the patients never survive long enough to be tapped twice. In the 68 cases investigated by Ramsbottom 45 were cases of uncomplicated alcoholic cirrhosis, but in only 39 of these were the notes complete enough for the duration of the ascites to be ascertained. Of these cases seven showed temporary improvement after ascites had occurred, and for periods varying from two to ten months the patients were able to resume their work, but in only one case was there any sustained improvement after paracentesis abdominis had been performed. In the remaining 32 cases the average duration of life after the appearance of ascites was 98.6 days. Of the 45 cases of uncomplicated cirrhosis 14 died before tapping was necessary, 14 were only tapped once, and 10 were tapped twice, and of the remaining seven cases only one survived long enough to require tapping more than five times. In the nine cases of simple chronic peritonitis the average number of days survived after the appearance of ascites was 624. In twelve cases where there was cirrhosis and peritonitis combined the average number of days survived after the appearance of the ascites was 360. From a comparison and investigation of these figures Ramsbottom draws the following conclusions:—"(1) That in the great majority of cases of alcoholic cirrhosis of the liver in which the peritoneum is not thickened as shown post mortem, ascites is a terminal event. (2) That there are a few cases of alcoholic cirrhosis of the liver which survive some considerable time after the appearance of ascites, and in which there is no evidence of chronic peritonitis revealed at the autopsy. (3) That there are again cases of alcoholic cirrhosis of the liver in which ascites is of much less prognostic significance, in that the fatal termination is even more remote from the incidence of this phenomenon. In such, post-mortem investigation invariably reveals the co-existence in a greater or less degree of chronic peritonitis, and they approach in clinical type the condition of simple chronic peritonitis." K.

Enuresis Nocturna.—Allen (*Jour. R.A.M.C.*, October, 1906) reports a case of this condition which occurred in a soldier of over ten years' service. The patient was brought under his notice with a view of invaliding him from the service, he having been treated for two months in hospital for incontinence without any benefit. On investigation it appeared that the condition had only appeared during the last few months, and the man had never suffered from it prior to enlistment. Some months previous to the onset of the incontinence this patient had been invalided home from India on account of enteric fever, and Allen found that the man was suffering from simple polyuria. This he believes to be an irritative polyuria due to the toxæmia of the enteric fever, and suggest this as an important causative factor in cases of incontinence occurring in adults. K.

The Immunity of Heart Cases from Phthisis.—Snow (*Amer. Jour. Med. Sciences*, October, 1906) states that whether organic heart diseases do or do not grant immunity from pulmonary tuberculosis depends on the presence or absence of a co-existing, long-standing passive hyperæmia in the pulmonary circulation. Thus it is found that organic valvular diseases of the right side of the heart which are productive of pulmonary anæmia are most frequently associated with phthisis; while similar diseases of the left side of the heart when accompanied by well-marked hypertrophy and dilitation are rarely followed by tuberculosis of the lungs, and not infrequently effect an extinction of a previously existing tuberculosis. These observations suggest that in the treatment of incipient phthisis patients should be urged to indulge in physical exercise in the open-air sufficient to produce "severe congestion of the lungs." This should be effected "not by mere gentle walking or driving, but running until the induced congestion of the lesser circulation interferes with the free action of the right ventricle and forces temporary rest." Snow quotes with approval the remark made half in jest by Elbert Hubbard that "tuberculosis is but a form of laziness." K.

Unrecognised Etiologic Factor in Summer Diarrhœa of Infants.—Walsh (*Med. Record, New York*, September 18th, 1906) calls attention to the cathartic property in the grasses which form the food of so many cows from spring to autumn. This property disappears when the grass is dried in the form of hay. The mortality curve follows the life of this form of vegetation, reaching its maximum in July, then gradually declining. Infants get the full physiologic effects, and often the toxic effects of the aperient properties in the milk from grass-fed cows. From October to May there is almost none of this diarrhœal tendency apparent. Sterilisation does not destroy this poison, which is a chemical one. The cow whose milk is used for infants should be kept off the pasture, and should be staff-fed, as in winter. The chemistry of the grasses, Walsh states, offers a comparatively new field for study. D.

Intestinal Origin of Pneumonia and other Pulmonary Infections.—Calmette (*Presse Medicale, Paris*, 1906), recently announced that tubercle bacilli fed to animals in his experiments passed rapidly through the intestinal wall, and were soon found in the lung, without leaving a trace of their passage. Similar tests were equally positive when finely pulverised charcoal or other insoluble particles were fed to the animals instead of tubercle bacilli. In another series of tests pneumococci were ingested by the animals in the same way, and with the same result—that is, the pneumococci were found accumulated in large numbers in the lungs with much congestion but no lesions. None of the animals sickened. It is probable that the animal organism is able to take care of these bacilli unless the vitality is depressed from some other cause. D.

Peptic Ulcer of the Œsophagus.—Jileston (*St. Louis Med. Review*, September, 1906 reports three cases, all of them terminating fatally. In the first case, that of a woman, æt. 58, the ulcer was situated 3 cm. above the cardiac opening of the stomach. The ulcer did not manifest itself until it perforated. In the second case, a man, æt. 59, the lower end of the œsophagus for a distance of 11 cm., was denuded of mucous membrane, except for a few small islands. The ulceration was very shallow, not involving the muscular coat. In a third case, a woman, æt. 37, there were several ulcers in the œsophagus, and also a chronic ulcer of the stomach, which perforated, causing the fatal peritonitis. D.

Effect of Dry Diet in Nephritis.—Ekehorn *Archiv. f. Klin. Chir., Berlin*, 1906) has been experimenting with a dry diet in cases of nephritis, and he found that

while in health the specific gravity of the urine increases in proportion to a decrease in its amount, in nephritis a dry diet lowers the freezing point of the blood. The amount of urine was reduced, but the sp. gr. did not rise to correspond. The kidneys were incapable of secreting a concentrated urine. D.

Anatomic Leucæmia without Leucæmic Blood.—Ewald (*Berlin Klin. Woch.*, 1906) describes a case with autopsy in which the symptoms indicated acute myeloid leucæmia running a fatal course in about seven weeks. The patient was a robust man of 37. The autopsy disclosed hyperplasia of the spleen, lymphomatous infiltration of the liver and kidneys, raspberry jelly bone marrow, hæmorrhage in kidney and stomach, fatty degeneration of heart with enlargement and pericarditis with adhesion. The microscopic findings were also those of leucæmia. At the same time the blood did not present any of the characteristics of leucæmia, and there were no pains in the bones and no enlargement of the peripheral glands. The lack of the latter and the negative blood findings, as well as the rapidly fatal course of the disease, spoke against splenic anæmia, and nothing was found to indicate a septic process. D.

Ocular Signs in Leucæmia.—Stock has studied the eye symptoms in leucæmia and Hodgkin's disease, and states that the so-called leucæmic retinitis is seen as often in lymphoid as in myeloid leucæmia; but, that from the retinal changes no differential diagnosis between the two varieties can be made. The distinctive bright yellow colouring of the back of the eye observed in some cases of leucæmia is probably produced by an accumulation of leucocytes in the choroid coat. In acute leucæmia, which is usually lymphatic, retinal changes have only rarely been observed. Still, in some cases extreme curving and dilatation of veins has been noticed, following which hæmorrhages into and characteristic cloudiness of the retina have taken place. As regards leucæmic tumours within the orbit, two theories of their origin may be held, according to the position they occupy. One is that they are merely hypertrophied pre-existing lymph masses, and the other is that they are metastatic growths, formed by proliferation of leucocytes which have escaped from the blood vessels. Probably both theories are correct. M.

Effect of Alcohol on Pancreatic Secretion.—Gizelt (*Pflügers' Archiv. f. d. grs. Physiol.*, Bd. 111, S. 620) makes a preliminary report of his investigations in connection with the above. He finds that when 50 cc. of a 10 per cent. alcoholic solution are introduced into the rectum or stomach of dogs who have a permanent pancreatic fistula, a secretion is set up in from 15 to 20 minutes, and persists for two or three hours. If the vagi nerves are previously cut, however, no secretion takes place. When the alcohol is injected subcutaneously a similar outflow of pancreatic juice takes place, but not when the alcohol is introduced directly into a blood-vessel. This last fact is supposed to be caused by the alcohol exerting an injurious effect on all the cells of the body, including the pancreas. This is supported by the fact that even the introduction of acid into the duodenum does not give rise to any secretion after the injection of alcohol in this way. Gizelt also finds that all the ferments are increased when alcohol is given by the stomach, and especially the fat-splitting one. The action of the alcohol is supposed to be on some precursor of the various enzymes concerned. M.

The Fat-Splitting Ferment of Gastric Juice.—Vollhard has proved that a fat-splitting ferment can be isolated from the gastric juice, and this has now been further investigated by Fromme (*Beitr. Z. Chem. Physiol. und Pathol*, Bd. 7, S. 51). The last-named author finds that a glycerine extract of the cardiac end of the gastric mucous membrane has a strong fat-splitting power, the power increasing with the length of time of extraction up to five days. A second and a third extraction even yields a juice of very considerable strength, and similar properties are found in the glycerine extracts made from dogs' stomachs. When, however, the mucous membrane is left exposed to the air for 24 hours, the extract is quite inert. This *lipase* differs from the other ferments of the stomach in being hindered in its action by small amounts of hydrochloric acid, while, like pepsin, it is also inert in the presence of alkalies. It will not traverse a filter, and does not combine with glycerine. M.

Rontgen Ray Examinations of Stomach and Intestines.—Since the bismuth method has come into use for X-ray examinations, some important observations on the morphology and the motor functions of the stomach and intestines have been made; thus, for example, X-rays have been found to be the method most agreeable to the patient for determining the position and state of the stomach. Still, up to this the screen has been almost alone employed, and very few photographs have been taken. Reider has now made several observations on the photographic plate (*Münch. Med. Woch.*, 1906, No. 3), using bismuth either in suspension or solution, or even mixed up with the ingredients of an ordinary meal. He has in this way definitely determined that the long axis of the stomach is vertical. Radiographs of the intestine, after giving bismuth by the mouth and in enema, rendered most of the intestine visible, with the exception of the sigmoid flexure and the rectum, which lie in the cavity of the lesser pelvis. The screen shows the bismuth traversing the small intestine rapidly, while in the large intestine the movement is much slower, and there is often a considerable delay at the ilio-cæcal valve. The transverse colon does not lie horizontally, but forms an arch convex downwards and forwards. The writer thinks that this method may prove most useful in the diagnosis of motor insufficiency of the stomach and intestines, and may also give some aid in the observation of the action of drugs such as purgatives. M.

Antipepsin.—When digestion experiments are carried out with undiluted gastric juice, it is found that digestion is less energetic than when the fluid has been diluted. Various substances which hinder the process may also be present, and these have been investigated by Blum and Fuld (*Zeitsch. für Klin. Med.*, Bd. 58). The authors find, in accordance with Schiff's statements, that they are able to confirm the above statement with reference to dilution in certain stomach diseases, and they also find that the property of becoming more active with dilution is better marked in juice obtained from a fasting stomach than in that obtained after a fish meal; it is also more marked when the secretion is abundant and being poured out rapidly. The hindering substance is in all probability a true antipepsin, a conclusion towards which Danilewski's investigations had already pointed. It is thermostabile, and can thus be separated from pepsin. The authors tried its effect in certain cases of disease, and found that it had a strong inhibiting effect on the hypersecretion found in carcinoma ventriculi and in chronic gastric catarrh. The antipepsin can be recovered from gastric juice that has been employed to digest various albumins, and is also present in commercial pepsin. It is strongly resistant to alkalies, and is precipitated by alcohol, but not by ammonium sulphate. M.

The Sanitation of Cairo.

IT is announced that the Egyptian Government has at last decided to undertake the sanitation of Cairo, and Mr. C. Carkeek James, a distinguished Anglo-Indian sanitary engineer, has been entrusted with the execution of a scheme. It is generally believed that the supply of a proper system of drainage will entail seven years' work and an expenditure of at least £E5,000,000, but all such estimates must be accepted with caution in the absence of sufficient *data*. Mr. James is, and will be for some time, engaged in a thorough study of the existing sanitary conditions o the capital.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CHANGE OF OUR OFFICE ADDRESS IN DUBLIN.

The Dublin Office of this Journal has been removed from 16 Lincoln Place to 18 Nassau Street. The latter premises are larger and more suitable, and will be open from ten to six daily, and on Saturdays from ten to two. Subscribers to the Journal and others desiring information regarding vacancies, *locum tenentes*, and medical matters in Ireland generally, can always obtain it by applying to the Manager either by letter or personally.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

DR. S. R.—None of the serums so far prepared for use in scarlet fever have gained any confidence in this country. Some Continental writers have found one or another of them hopeful.

OPHTHALMIC.—Dionin is a recognised agent. A 5 per cent. solution is valuable in deep-seated ocular pain. The first sensation on application is one of smarting.

DR. HALL.—The Thibetan medical philosophy is not unlike that of Christian Science, as the teaching is that all disease is the result of vice or wickedness. Their treatment is principally "natural," and their surgery barbarous.

NORTHUMBRIAN.—The salaries paid to assistant medical officers in the London County Council Asylums are according to seniority. The senior assistant receives £300, rising to £400, a year, with board, lodging, and washing. The junior gets £150, with the same emoluments. The others in proportion.

T. TWEED.—The St. Andrew's Ambulance Association is an independent organisation doing the same work in Scotland as the St. John's Ambulance Association does in England. If you are now resident in Yorkshire you should apply to the latter.

D. W.—The physician you name has not received titular distinction; but we should be glad to see his merit recognised if it pleased His Majesty to do so.

S. T. (Tunbridge Wells).—We cannot make any recommendation such as you desire. If you wish for an opinion on the question, you should consult your own medical attendant.

R. N.—The Mediterranean Commission found that the chief source of Malta fever was goat's milk, and the civil, naval, and military authorities in the island are now trying to suppress the use of such milk, or to insist on it being boiled.

MICRON.—"Modern Microscopy," by Martin J. Cole, 4s. net (Baillière, Tindall, and Cox) is the smallest book we know of. There has just been published a very good, larger book on the subject by A. E. Wright, M.D., price 21s. net (Constable and Co.).

J. E. HORTON.—Everything depends on the nature of the agreement. These partnership contracts are frequently the source of subsequent estrangement between friends. It will afford us pleasure to act as arbitrators if both will agree to abide by our decision.

EDINBURGH STUDENT.—The book is in our to-day's list of "New Books and New Editions," published in another column. We cannot answer your query until we have read the book. In any case you cannot do wrong in taking Monro's "Manual of Medicine" as a very safe and practical guide.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 7th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. C. H. Roberts, Dr. Handfield-Jones, and Dr. H. R. Andrews. Short communications:—Mr. A. Doran: Myomectomy during Pregnancy and Labour at Term in an Elderly Primipara, with Notes on Similar Cases. Paper:—Dr. W. R. Pollock: The Present Position of External Version in Obstetrics with a Suggestion of a New Method of Performing it.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. M. Collier: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. G. A. Sutherland: Vomiting in Children.

THURSDAY, NOVEMBER 8th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Papers:—Dr. H. Spencer: On the Treatment of Extra-uterine Pregnancy.—Dr. W. Harris: The Causation and Treatment of Some Headaches.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens. 8.45 p.m.: Special Meeting to Discuss the Advisability of Joining in the Proposed Union of the London Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. J. H. Swanton and Mr. J. F. Jordan. Papers:—Dr. J. H. Swanton: Note on a Specimen of Cystoma of Ovary with Thyroid Tissue Present. Dr. Aarons: Notes on the Medical Treatment of Uterine Hæmorrhage.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. J. F. H. Broadbent: Aortic Regurgitation in Later Life.

FRIDAY, NOVEMBER 9th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m.: Papers:—Dr. E. Diver: A Principle of Treatment Suggested for Some Untoward Fractures, especially of the Femur. Mr. C. Symonds: Multiple Strictures of the Ileum, Resection, Recovery. Mr. E. M. Corner: Rotatory Subluxation of the Atlas. Mr. J. Clarke: Case of Congenital Deformity of the Spine.

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.:—Mr. W. Dodd. Clinique. (Eye.)

Vacancies.

Gloucester County Asylums.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

County Asylum, Dorchester.—Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Derbyshire Royal Infirmary.—Superintendent and Secretary. Salary £300 per annum. Applications to Walter G. Carnt, Secretary-Superintendent, Royal Infirmary, Derby.

Nottingham City Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with apartments, board, &c. Applications to the Medical Superintendent.

Sheffield Royal Infirmary.—Secretary. Salary £400 per annum. Applications to the Chairman at the Infirmary.

Liverpool Hospital for Consumption and Diseases of the Chest.—Pathologist and Assistant to the Honorary Medical Staff. Salary £150 per annum. Applications to Alfred Shawfield, Secretary, 77A, Lord Street, Liverpool.

Staffordshire County Asylum, Cheddleton, Leek.—Junior Assistant Medical Officer. Salary £150 per annum, together with board, furnished quarters, and washing. Applications to the Medical Superintendent.

Barnsley Hall Asylum, Bromsgrove, Worcestershire.—Senior Assistant Medical Officer and Deputy Medical Superintendent. Salary £200 per annum, with furnished quarters, board, washing, and attendance. Applications to the Medical Superintendent.

Richmond District Asylum, Dublin.—Clinical Assistant. Salary £80 per annum, with furnished apartments, &c. Applications to Conolly Norman, Medical Superintendent. (See advt.)

Appointments.

BOND, B. M., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Fulham and Hammersmith District of the county of London.

CURRIE, J., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Lees District of the county of Lancaster.

ENGLISH, HOWARD, Resident Surgeon to Richmond, Whitworth, and Hardwicke Hospitals.

HAWKINS, ARTHUR, M.R.C.S., L.R.C.P., House Physician at the Royal Devon and Exeter Hospital, Exeter.

NESBITT, G. E., Resident Physician to Richmond, Whitworth, and Hardwicke Hospitals.

RENTON, JAMES M., M.B., Ch.B.Glasg., House Surgeon at the Tottenham Hospital, London, N.

SINIGAR, H., M.D.Lond., Certifying Surgeon under the Factory and Workshop Act for the Southall District of the county of Middlesex.

TURNER, G. G., M.B., M.S.Durh., F.R.C.S.Eng., Honorary Assistant Surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne.

Births.

CRAWFORD.—On Oct. 25th, at Palmerston, Swanley, Kent, the wife of J. Dawson Crawford, M.D., of a son.

ROBINSON.—On Oct. 30th, at the Grange, Blechingley, Surrey, the wife of C. A. Robinson, B.A., M.B., B.C.Cantab., of a son.

Marriage.

MALLINSON—SCOTT.—On Nov. 1st, at St. Margaret's Church, Ilkley, Arthur William, elder son of the late William Arthur Mallinson, Leeds and Ilkley, to Helen Brown, youngest daughter of Thomas Scott, M.D., Ilkley.

Deaths.

CLARKE.—On Nov. 3rd, at Bournemouth, Benjamin Clarke, F.R.C.S., L.R.C.P., late of Upper Clapton, in his 86th year.

ELLIS.—On Nov. 3rd, at Balmoral, Bournemouth, Heber Dowling Ellis, M.D., in his 67th year.

MAIN.—On Nov. 1st, at 24 Alexandra Villas, Finsbury Park, London, Joanna, wife of Robert Main, M.D.

THE MEDICAL PRESS AND CIRCULAR.

VOL. CXXXIII. WEDNESDAY, NOVEMBER 14, 1906. No. 20

NOTES AND COMMENTS.

The Amalgamation of London Medical Societies.

WE are glad to learn that the amalgamation of the Gynæcological and the Obstetrical Society has almost become *un fait accompli*. At the present moment a report, dealing with the main outlines of the project, has been adopted by a Joint Committee of the two Associations, and has also been adopted by the Council of the Obstetrical Society. It has now to be brought before a general meeting of each Association, and, if it is passed by them, it will be finally ratified by a joint general meeting. We have been strongly in favour of such an amalgamation, and congratulate the Associations on having successfully bridged over the many difficulties. Not alone in London will the union be an advantage to obstetricians and gynæcologists, but also throughout the country. We shall be greatly surprised if the first result is not an immediate influx of new members.

The Ophthalmological Society declines with thanks.

THE Ophthalmological Society of London, however, hold a different view. On the 10th inst. a special meeting was held to consider the question of amalgamation. Lo and behold! the whole meeting, *una voce*, declared dead against the scheme. Not a single vote was recorded on the other side. So that one leading London society, at any rate, has declined to merge its identity in an amalgamation scheme. The result is one of significance, and emphatically demonstrates that the scheme will be anything but universal.

Sidelight on Medical Education.

SINCE the publication of an article on this subject in our last issue, our contemporary the *British Medical Journal* has published a letter from Professor Francis Dixon in which he takes very grave exceptions to the comments made by our contemporary, and requests that the latter will either withdraw its statements or justify them by republishing the tables in question together with his remarks upon them. The reply vouchsafed to him is flippant in the extreme, and does not appear to us to be either dictated by the spirit proper to the occasion or couched in dignified language. "We are sorry to have annoyed Professor Dixon," runs the editorial note, "who, indeed, has our entire sympathy, for it is always annoying to be misunderstood, and we are suffering in the same way." And then a little further on it continues, "for the sake of our space and for his satisfaction we will gracefully allow him to assume that the rest of his strictures and observations are justified." Such heavy wit is singularly out of place in dealing with a matter which is capable of the plainest proof. If Dr. Dixon is wrong our contemporary should clearly say so and prove its statement. If, on the other hand, he is right, our contemporary, we are sure unintentionally, has made a statement injurious to the reputation of Irish medical bodies, and in such a case one would have expected a more gracefully worded apology.

Testimonials to Nurses.

DR. J. B. NEAL, Medical Superintendent of Wandsworth Infirmary, is much to be congratulated on emerging scathless from the law-courts last week. A male nurse who had left the Infirmary with a good character, gave Dr. Neal's name as a reference to a gentleman who proposed to engage him. Dr. Neal, confusing the man with another attendant, said that he had had mental trouble through an accident. This unfortunate mistake was made the subject of an action by the attendant, who contended that malice towards him had been shown by Dr. Neal. There was no doubt about the mistake and the case might have gone badly for the defendant if the judge had not taken the common-sense view that the occasion was privileged. At the same time, even privilege must have its limitations, and the defendant probably could not have come much nearer the partition. Though there was not the slightest suspicion of malice in his statement he will probably exercise more caution in future in discharging so responsible a duty as a referee to a man's character.

Herbalist and Arson.

A SCAMP who had the impertinence to describe himself as a "professor and a doctor" was tried at Lancaster Assizes on November 8th. This "professor" kept a shop, as is usual with "professors" of a certain type, and he seems to have belonged to that peculiar people, the "herbalists." Herbalising apparently did not flourish with this particular professor, for he, after insuring his shop for £400, was seen by a witness deliberately to attempt to burn it down at night. Only £8 worth of damage was actually done. The Fire Company not only did not pay this, but they actually initiated a prosecution. The jury took a lenient view, and only convicted the "professor" of attempted

arson, and the judge gave him eighteen months' imprisonment. When will the press stop heading paragraphs of this sort, 'Doctor' convicted of Arson" ?

LEADING ARTICLE.

THE GENERAL MEDICAL COUNCIL ELECTIONS.

THE advent of another election of direct representatives of the profession to the General Medical Council is arousing more than ordinary interest. There are various explanations for this alertness, and among them it seems not unreasonable to attribute some influence, at any rate, to the awakening of the general practitioner. There can be little question that the times are out of joint for the rank and file of the medical profession. The stress of competition of all kinds has fallen with such crushing effect that it is no longer possible to maintain the average professional income. Under these cricumstances, as pointed out in the letter of a correspondent published elsewhere in our present issue, it behoves us to be calm and philosophical in our discussion of the present issue. His views are strongly and concisely stated, and in the main reflect those that have been from time to time advocated in the MEDICAL PRESS AND CIRCULAR. He points out that the addresses of the candidates are notable for the absence of enthusiasm for reform, a feature that is admirably illustrated by the fact that only one candidate accepts the whole Bill drawn up by the British Medical Association. With his remark that the demand for the increase of the number of direct representatives "goes to the heart of things," we heartily agree. The General Medical Council is not a representative body, and until it is reconstituted upon lines of popular franchise, the general practitioner will be left wandering in the wilderness. The present haphazard control of the medical profession is rendered worthless and irritating in the absence of any protection against irregular competition. What encouragement is there to an honourable man to practice his profession on lines of the highest morality, when he cannot pay his rent and his tradesmen's bills, while at the same time the bread is taken out of his mouth by quackery of every kind. The General Medical Council is composed of men who have the interests of close corporations to defend, and who are absolutely out of touch with the general practitioner. When any attempt is made to increase the number of direct representatives, the Council meet the suggestion with a sanctimonious *non possumus*. Not long ago, however, the learned President of that body admitted that the Council had in various directions made a law unto themselves. Why should they evade so obviously just and reasonable a demand as the increased representation of the medical profession. If they had no fear of the democratic element, it is safe to assert that the direct representatives would long ago have been added to. So vital is this point that there is no great need to discuss side issues in this or any other Council Election. Should the medical profession ever establish a complete and adequate organisation, the game will speedily fall into their hands. They have the overwhelming power of the boycott, and in a few months the whole of the classes who control the Council as nominees of close corporations could be reduced to reason. Undesirable as it would be to raise an internecine strife, it is nevertheless to be feared that sooner or later the matter will be settled by a sharp and decisive conflict. The General Medical Council, like the House of Lords, is practically an irresponsible body. The presence of a faint leaven of elected members is much as though the Lords permitted a dozen representatives of the people to their benches. There is one way in which a death struggle may be averted, namely, by a gradual substitution of popular election for that of nomination of the representatives of the various medical corporations. Why, for instance, should the members of the Royal College of Surgeons of London be disfranchised in a matter of such vital importance as their representation on the only body that has the smallest chance of protecting or advancing their material interests ? Why should the Scotch licentiates be refused a voice in the election of the gentlemen who represent the ancient colleges of Edinburgh and Glasgow ? The only defence is that of privilege, and of class government. The General Medical Council is an autocratic and irresponsible non-elected body made up for the most part of representatives of corporations that are no less irresponsible and hopelessly out of touch with the spirit of the times. When the general practitioner really asserts himself, one of his first demands will be a share in the control of his own colleges, and a voice in the election of his college representatives. Meanwhile, it is the duty of every voter to make up his mind clearly as to what pledges he wants from the candidate to whom he is willing to give his support.

NOTES ON CURRENT TOPICS.

Food and Dirt.

AT a recent meeting of the National Health Society, Sir Frederick Treves and Sir James Crichton-Browne made merry over the carelessness of the public with regard to its food supply. The former drew an amusing comparison between the habits of prehistoric man and those of his modern descendant in their manner of dealing with food, and the advantage did not rest with the product of civilisation. Both, Sir Frederick pointed out, carried meat on their bare heads, both deposited it on dirty floors, and both exposed it to the dust and dirt of the atmosphere. But the neolithic man at least saw his meat killed, which is more than modern man takes the trouble to do. Sir James Crichton-Browne, who followed, brought up "The Jungle" stories again, and referred to them with horror, denying that the panic

created had done any harm. Whatever may or may not be said about the author of that novel, if he has directed people in every country to pry into and reform their methods of food production and transit, he will have done some good by his tirade. The apathy of the public mind in this matter was illustrated by Sir James by mentioning that an outbreak of typhoid in West Ham has just been caused by the consumption of cockles from the same polluted creek which caused an outbreak at Southend four years ago. Truly there is little exaggeration about the saying that people in their lifetime have to eat a peck of dirt.

The Soap Trust and Health.

At the present moment, when the efforts of certain soap manufacturers to combine is being resisted tooth and nail by consumers, it is well to note that soap is not only a detergent instrument, but a great moral force. The object of trusts and combines is either to lower working expenses or to raise prices; in most cases it is both, and therefore the interest of the organisation is always against the public. In matters of luxury there is no need for us to say anything, but in matters affecting the public health and morals so intimately as does soap, it is of the utmost importance that medical opinion should make itself heard. The need of the moment is to realise that the day of the antiseptic has passed, and the clearer dawn of asepsis, which is cleanliness, has broken. Lister showed that wounds suppurated because of bacterial contamination, and he used antiseptics as curative agents. The modern development of Lister's doctrine is the prevention of contamination by scrupulous cleanliness, not only in the care of wounds, but in that of everything around us. To this end soap is a prime necessity, and it is not going too far to say that cheap soap is one of the most important requisites of hygiene. Anything that raises the price or lowers the weight of a pound of soap has the unsparing condemnation of the medical profession.

Discharge of Army "Incurables" from Netley.

The recent announcement by Mr. Haldane that a number of incurables were to be discharged from Netley has naturally excited a good deal of public interest. There is no particular political aspect involved, inasmuch as the present Liberal War Minister is simply carrying out the policy of his Conservative predecessor. So far as the moral obligations of the nation towards its soldiers are concerned, however, a point of considerable importance is involved. Many a soldier who has fought bravely for his country dies in a workhouse. Many of those who endured wounds, disease, and hardship in South Africa have drifted into unemployment, crime, and the workhouse. It is not apparent why the private should not be pensioned for life as well as the superior officer. The discharges mentioned by Mr. Haldane, however, if we understand the matter aright, apply to sufferers from intractable syphilis. The stern moralist would naturally advance strong arguments against helping a man bear the punishment of his own sensuality. On the other hand, it may be urged that if cured syphilis confers no disability, why should the unhappy man disabled by uncured syphilis pay the further additional penalty of loss of pension? Further, the soldier is an unmarried man, in nine cases out of ten, by the regulations of the service. The moralist will do well to turn his earnest attention towards increas ing the marriage facilities granted to our troops.

A State Medical Service for Ireland—Important Announcement.

A special General Meeting of the Irish Medical Association will be held to-day at 2 p.m. at the Royal College of Surgeons to consider the action which the Association should take with regard to the Report of the Poor-law Commission just issued. In addition, the proposal to convert the Irish Poor-law Service into a State Medical Service will come up for consideration. We urge on those of our readers who are members of the Association to make it their business to attend the meeting, as the decision to be arrived at will be fraught with the greatest importance to the medical profession in Ireland. Medical men will do well to remember that should a State Service be adopted, the rights of all existing medical officers will be fully conserved and in addition they will receive the benefit of such increase in salary as may be decided upon. They will also become entitled to a pension as of right. It is obvious that the proposal will be strenuously resisted in some quarters, and medical men who desire to keep an open mind will do well to insist that those who advise opposition to it should give very definite reasons for their advice. Poor-law medical officers have now before them a definite opportunity of obtaining the reforms for which they have so long pressed, and if they deliberately cast it on one side, they will find it difficult in future to obtain that practical sympathy to which the present condition of the Poor-law Service entitles them.

Anti-Vivisection Tactics.

The methods that are being used by certain anti-vivisectionists to cast slurs on the Royal Commission sitting to enquire into experiments on animals deserve to be carefully noted. Their first step was to attempt to discredit the Commission by complaints against its *personnel*, which were finally reduced to absurdity, seeing the ample representation given to anti-vivisectionists, by the complaint that there was no "expert anti-vivisectionist" to voice their claims. The next step was loudly to cry out against the determination of the Commission to sit *in camera*. Now this decision, which was arrived at by resolution of the Commission, and had nothing whatever to do with the Government, was come to for the simple reason that the room in which sittings are to take place is too small to hold anybody beyond the Commissioners and witnesses, and even they are crowded. Of course, all evidence offered will

be received, and the proceedings published in full at the end of the sittings. The next unworthy step was to supply the press with sensational articles suggesting that certain disgusting horrors were being concealed from public notice. An article appeared in the *Daily Mirror* of November 6th, describing in vivid language certain acts alleged to have been carried out by French experimenters, with the comment: "The class of evidence which will be discussed at this private conference (*i.e.* the Royal Commission) is intensely interesting to the British public. It is represented by this typical statement . . ." Moreover, a bogus report of evidence alleged to have been given by Professor Thane, Inspector under the Vivisection Act, was sent round to the papers, and published at least by one of them in good faith. This report was contradicted authoritatively the next day. It is by actions of this sort that the disgust of fair-minded people is aroused.

A Striking Experiment in Infantile Mortality.

THE Mayor of Huddersfield, in resigning office last week, was able to put on record an experiment which deserves to rank high as a distinguished service to the community. While others were content to wring their hands and moan despairingly over the vast infantile mortality, Alderman Benjamin Broadbent, of Huddersfield, tackled the problem on first principles. Two years ago, on assuming office as Mayor, he offered £1 to the parents of each child born during his mayoralty who attained the age of twelve months. The main feature of the experiment was to see if by constant watchfulness and helpfulness on the part of a small band of voluntary lady workers any appreciable reduction could be effected in the infantile mortality rate of Longwood. The previous ten-yearly average in Huddersfield had been 139, and that of Longwood 122. The actual figures will be found in our medical news column, but the broad result is that, taking the most adverse view, the infantile mortality has been reduced to less than half the average rate Alderman Broadbent may be congratulated upon having made one of the most remarkable experiments ever attempted in public health administration. The reduction of the preventable margin fully justifies his own epithet "astounding." Henceforth there can be no more excuse for communities that tolerate this yearly death-toll of the "innocents," inasmuch as this enterprising Yorkshire Mayor has proved to demonstration that for the most part the sacrifice is preventable and has been prevented.

When Analysts Differ.

IT says much for the capabilities of medical men that so many of the accusations brought against them are based on trivial details. Persons connected with the lay press are too often accustomed to constitute themselves censors regarding scientific matters, and although their ignorance may be evident to the profession, their misleading headlines often seriously lower the prestige of their victim among his clients. The Public Analyst for Dorset, Dr. Comyns Leach, recently reported a sample of milk taken under the Food and Drugs Acts as containing 2.70 per cent. of fat. Somerset House, to whom the reserve sample was submitted two months after being taken, found the percentage of fat to be 2.77. The Government Analysts use methods for the estimation of fat which are different from those usually employed by Public Analysts, and taking that fact into consideration, together with the long period that elapsed between the two analyses, the difference is practically nil. The case was dismissed. Yet, in spite of that circumstance, the editor of the *Western Gazette* apparently felt justified in adopting as a headline: "Singular Case at Portland, Analysts Disagree!" Did he but appreciate the difficulty of analysing sour milk and the experimental errors of milk analysis, he would perhaps perceive the ridiculous character of his heading, and would not have thus inferred incapacity on the part of the medical man who acts as County Analyst. It should be remembered that when discrepancies occur in analysis, the Government is invariably credited with giving the correct figure, while the Public Analyst, who has had the advantage of analysing the milk while fresh, is gratuitously assumed to be wrong.

Colwyn Bay Murder Trial.

AN unusually interesting medico-legal case was decided at Ruthvin Assizes on November 1st. A servant girl was indicted for the murder of her newly-born child, and extraordinary facts came to light during the hearing. It seems that the child was born while she was straining at stool in an outdoor privy, and a fellow-servant later found he holding the child's leg in one hand and a hatchet in the other, while she hacked wildly at the pan of the closet. The subsequent history was not quite clear, but they both had tea together, the mother saying the child's body was on the dust-heap. The Treasury put forward the view that the girl had murdered the child with the hatchet, because not only did they have the fellow-servant's evidence, but the child itself was much cut about, and its head was separated from the body. Two medical witnesses were called and testified that severance with a sharp instrument was the only possible explanation of the condition of the body, and that the child had had a separate existence. The view put forward by the defence was that the child's head had been stuck in the pan, and that the mother had dragged the body away from the head in her endeavours to save him, the hatchet being used to cut away the pan. Three medical witnesses were emphatic that the head had been torn off and not hacked off, and threw grave doubt on the evidence that the child had actually lived. Eventually the jury found the girl not guilty, as indeed they were bound to do on the evidence. The case created great interest, and the usual sneering remark about the differences of doctors were freely made.

Exit "Capsuloids."

The quacks, as might be expected, make much capital out of baldness and its "treatment." They are always quick to seize upon the frailties of mankind, one of which is a little pardonable vanity in the matter of his growth of hair. Baldness they proceed to attack by a host of remedies, external and internal. It has been pointed out again and again in these columns that no internal remedy is known that will consistently induce a growth of hair. In spite of that fact, various nostrums of the kind are sold to the public on the pretence that they will cure baldness. Were such a remedy known, it would be welcomed with open arms by the medical profession, which is always eager to remedy the infirmities of mankind. For some time past extravagant claims have been advanced as to the effect of an internal remedy upon the growth of hair. The company has been brought to a standstill by a verdict in the High Court, declaring the name "Capsuloids" to be an infringement on Messrs. Burroughs and Wellcome's trade-mark, "Tabloids." It forms a scathing commentary on the quack medicine trade to learn in the course of this trial that upwards of £1,000 a month had been spent in advertising a preparation for the claims of which it is impossible to find any reasonable scientific ground.

The Tenure of Post-Office Surgeoncies.

Recently the attention of the House of Commons was called to the age-limit of sixty which the Postmaster-General proposes to impose upon all medical appointments in his department. It is clear that the sudden imposition of such a condition of tenure must inflict a certain amount of hardship upon existing holders of such appointments. There are obviously sound reasons for establishing some general rule with regard to age in relation to efficiency. A rigid imposition of any age limit, however, would rob the State of many valuable servants, not only in the Post Office, but in every other branch of the public service, paid or unpaid. If a man be unfitted to perform the duties of a medical officer at sixty, he is hardly likely to discharge more efficiently those of a general officer, of a judge, or of a cabinet minister. Yet a man is considered a young man in politics at fifty; prime ministers are often seventy to eighty years of age; generals conduct active campaigns at seventy, judges sit at eighty. Why, then, should inoffensive post office surgeons be turned out at sixty? Much the same line of reasoning applies to honorary medical appointments at lay hospitals. In any case, if a new rule is to be applied it would obviously be more just not to make it retrospective in its first application.

PERSONAL.

Sir Alfred Downing Fripp, C.V.O., C.B., has been created Knight Commander of the Royal Victorian Order.

Upon William Maurice Abbott Anderson, M.B., has been conferred a membership of the fourth class of the Royal Victorian Order.

Dr. D. K. McDowell, C.M.G., Principal Civil Medical Officer Straits Settlements, leaves England on the 23rd inst. for Singapore to resume duty after a lengthy leave of absence.

A knighthood has been bestowed upon Dr. Charles F. Hutchinson, who during the last Parliament was returned for the Rye Division of Sussex. Sir Charles is a Liberal in politics.

One of the most popular of the birthday honours will probably be that of Professor John W. Byers, who has held the chair of midwifery and diseases of women at Queen's College, Belfast, since the year 1893.

The well-deserved honour of knight bachelorhood has been conferred by His Majesty upon Professor Rupert William Boyce, M.B., F.R.S., Dean of the Incorporated Liverpool School of Tropical Medicine.

Among the birthday honours, Mr. John Tweedy, President of the Royal College of Surgeons, London, has received the honour of knighthood. Mr. Tweedy has long been connected with University College as Surgeon and Opthalmic Surgeon.

Another Royal recognition that will be popular amongst medical circles is the C.M.G. bestowed upon Mr. Petro James Michelli, the well-known secretary of the Seamen's Hospital Society, in connection with his services to the London School of Tropical Medicine.

At the annual general Court of Governors of Guy's Hospital, Prince Francis of Teck and Messrs. Otto Beit and Waldorf Astor were elected to the corporation to fill vacancies caused by the deaths of the Earl of Leven and Melville, Mr. Rodolph Hankey, and Mr. Alfred Beit.

Mr. Edmund Owen, F.R.C.S., Consulting Surgeon to St. Mary's Hospital, Paddington, and to the Great Ormond Street Hospital for Sick Children, has been nominated by the Council of the Royal College of Surgeons, England, to deliver the Bradshaw Lecture, on December 12th, the subject of which will be "Cancer: Its Treatment by Modern Methods."

A Companionship of St. Michael and St. George has been conferred upon Sydney Wilson Thompstone, F.R.C.S., in recognition of distinguished services as principal medical officer in Northern Nigeria. A similar distinction has been bestowed upon Wilfred T. Grenfell, M.R.C.S., Superintendent of the Royal National Mission to Deep Sea Fishermen.

The President of the Board of Education on the 13th inst. received a deputation urging the necessity of teaching hygiene and temperance in schools. Amongst the deputation introduced by Sir Thomas Barlow were Sir T. Lauder Brunton, Dr. John Robertson, Dr. James Niven, Miss Alice Ravenhill, Dr. James Macdonald, Dr. Langley Brown, Dr. Clifford Allbutt, Sir Victor Horsley, and Dr. G. A. Heron.

Sir Victor Horsley, who has been connected with University College as a student and as a teacher for 30 years, has resigned his Professorship of Clinical Surgery and Surgeoncy to the hospital on account of increasing duties. The Council adopted unanimously the following resolution:—"That the Council, having received with great regret Sir Victor Horsley's resignation of his Professorship of Clinical Surgery and his position of Surgeon to University College Hospital, whereby his official connection with the College is severed, desire to put on record their recognition of his long service to the College and the distinction he has conferred upon it by his eminence as a scientific investigator."

A CLINICAL LECTURE
ON
ERYTHEMA INDURATUM (BAZIN). (a)

By J. MAGEE FINNY, M.D.,

President, Royal Academy of Medicine in Ireland; King's Professor of Practice of Medicine.

GENTLEMEN,—You have been watching a case with me during the last week or two, and although it may not have appealed to your imagination, nor called upon your clinical acumen and resources, in the same way, and to the same extent, as cases of heart disease or nervous disorders have done, yet a little retrospect of the notes of the case cannot, I think, fail to show you that it is not lacking in pathological and clinical interest, and that it presents features and peculiarities well worthy of your investigation and consideration.

First of all, the disease which the following case illustrates is by no means frequently met with in Great Britain and Ireland, although it was spoken of as not uncommon in France by Bazin, who first described it. Possibly it may have been overlooked or confounded with other complaints. Then again the name of *Erythema Induratum* is misleading, as it has hardly any feature in common with any one of the many manifestations of the hydra-headed *Erythema multiforme.*

The principal features of the disease will be observed in the following notes of the case, taken by my clinical clerk, Mr. Gregg.

Case.—Maggie F., æt. 18, domestic servant, was admitted to Sir Patrick Dun's Hospital on March 27, 1906, on the recommendation of my friend, Mr. Albert Croly, F.R.C.S.I., complaining of swelling and of pains in her legs. About the beginning of February last she noticed reddish lumps making their appearance on her legs, on the inside of the calf and the parts below it, and, later on, others appeared on her arms. For the past three or four years, she states, she has had similar attacks each spring, but none so severe as the present one, and the discomfort and swelling of her legs, and the fear that some of the nodules would break, compelled her to give up her situation and seek medical aid. Patient is a robust, healthy-looking girl, well developed and fat, with a clear bright complexion, dark hair and good teeth, and weighs 11 stones. She does not remember having ever suffered from any serious illness other than the present, except that she is very liable to colds in her throat and swellings of the glands of her neck. On either side of the neck in the posterior and supra-clavicular triangles, around the lower jaw, and under the chin, a number of lymphatic glands may be felt enlarged, and those near the ramus show up as distinct swellings. They are freely movable and painless. The patient states they have been swollen for a number of years past, and that when she has a cold they swell up much more and cause loss of voice. Enlarged glands cannot be found elsewhere.

Careful examination failed to discover any disease or perverted function of any organ in the body other than the glands in the neck, and that menstruation, though regular, is very scanty, and lasts only half a day. On admission the legs were swollen about the ankles and pitted on pressure over the tibiæ. At the back and chiefly the inner sides of the leg, below the calf, a number of pale purplish-red swellings or nodules could be seen and felt, some the size of a small nut and others as large as a cherry or walnut, and while some were separate, others seemed to coalesce and became fused into hard irregular masses 1½ in. long by ½ in. wide, somewhat doughy to the feel. More lumps were to be made out by palpation than could be seen, and they lay deeper than in the skin. There were no nodules or swellings present over the front of the tibiæ. At first sight the œdematous legs, the discolorations, and the lumpy condition gave the idea that it was a case of varicose veins, but there were no veins visible in the calf or beside or behind the knees. There was no broken or suppurating nodule, though a few near the surface were soft and elastic, and gave the impression that they contained fluid. A similar state of nodules, though very much less numerous, was found in the upper extremities. In the upper third of the arm five or six bluish swellings, like small marbles, could be felt in the skin and under it, on the outer and back part over the insertion of the deltoid, and over the triceps. They were barely visible, but were distinct to handling. They were confined to the regions mentioned, and were not present in the forearms or over the ulnar surfaces. The nodules were not painful in the arms, and the discomfort complained of in the legs was rather due to the swelling and stiffness than the actual pain of the nodules. However, two or three were sensitive to the handling, and a tight bandage gave discomfort.

The treatment was simple and, fortunately, very successful. The girl was kept in her bed (the lower part of which was raised on blocks) for ten days; the bowels were well opened every few days with an aloes pill, At first sodium salicylate was given for five days, and then quinine sulphate was substituted.

The legs were gently rubbed in an upward direction, and a Domette bandage applied. In a week's time the larger indurations became much smaller and the colour of the nodules changed from violet-red to a more natural hue. At the end of the second week she was allowed up, wearing the bandages, and left the hospital the week afterward, to go to her home situated in good air high up in the Dublin mountains, promising to return to have the glands in the neck removed. It was very fortunate that the nodules disappeared by absorption, and that none of them had ulcerated, as usually the ulcers caused by necrosis are very indolent. In July she entered hospital a second time with a

(a) A Clinical Lecture delivered in Sir Patrick Dun's Hospital.

view to removal of the glands from her neck. Dr. Arthur Ball kindly took her into his charge, but he decided not to operate, as the glands gave her no trouble since March and were smaller. The legs and arms were quite free from all nodules, and there was no sign of swelling or discoloration above the ankles in the situation where the nodules had been.

The Pathology of Erythema Induratum is not conclusively determined.

There are two well-defined types, according to Whitfield (*Brit. Journ. of Dermatology*, August, 1905), the tuberculous and the non-tuberculous. The latter occurs in older patients, and runs a more rapid course, showing less tendency to ulcerate and causing less pain. The former, or the tuberculous type, is that to which I call your attention, and of which this patient is an example. From the frequency of the association of the cutaneous affection with tubercle, Bazin's disease is sometimes called *E. induratum scrofulosorum*, and Dr. Payne describes a case under this designation in the *Trans. Dermatological Soc.*, Vol. I., page 79. Opinions therefore differ as to the true pathology of the affection. Some consider it is but a rare variety of *E. Nodosum*, and deny it has any relation to tubercle; others, again, look upon it to be a cutaneous manifestation of tuberculous infection, and experimental inoculation has succeeded in producing general tuberculosis, although the bacillus has never been found. In 1905 Harttung and Alexander, (*a*) summarising a histological examination of five cases, state their belief that *E. Induratum* is a tuberculous affection of the skin of a hæmatogenous origin, and essentially an arterial and embolic condition.

Perhaps the chief interest of *E. Induratum* lies in its diagnosis, as it resembles E. Nodosum, syphilitic gummata, and phlebitic thrombosis.

From E. Nodosum, with which you are familiar, it may be distinguished by the following:—

(1) The situation of the nodules being in the soft parts in the back and sides of the leg below the calf, and their absence from the anterior and tibial aspects;

(2) The absence of the great blush and the painful bruise-like swellings common to E. Nodosum;

(3) The absence of all febrile symptoms and arthritic pains;

(4) The indolent course of E. Induratum with many relapses;

(5) It not uncommonly presents necrotic ulcerations which are very slow to heal up.

The fact that this young patient is a female, and scrofulous, while it strongly points to the tuberculous nature of the nodules and to "Bazin's disease," is not however sufficient to exclude *E. Nodosum*, as that disease is so often present in young women of her age and station in life. The occurrence of nodules in the upper arms is rare in E. Induratum, although a few cases are on record of such an extension; and Galloway (quoted by Crocker) gives a case in which nodules were present in all the limbs, shoulders and ankles. In E. Nodosum nodes in the upper extremities are a complication not very unusual, but it struck me as a remarkable aid to diagnosis that the situation of the nodules in this case was in the upper third of the arms and not in the forearms over the ulnar aspect, as we see it in E. Nodosum.

The diagnosis from syphilitic gummata hardly arose in this case, as it is in the ulcerative stage that the resemblance exists between the two affections. The age, history, cachexia will assist. Moreover, gummata are rarely present in the legs, they are few in number, and when they break down the ulcers occur rapidly, are sharply circumscribed, and covered with a purulent discharge, whereas in E. Induratum the process is slow and is one of necrosis.

The diagnosis from phlebitic thickening or thrombosis was readily made out in the absence of the symptoms characteristic of these conditions, and as no varicose veins were to be felt or seen in the usual situations, and, although the feel of the nodules and masses was somewhat like that of the thrombosed veins their colour, shape and course were sufficiently different to prevent a mistake.

(*a*) "Archiv. für Dermat. und Syph.," "Med. Annual," p. 206, 1906.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The Lecture for next week will be by Dr. G. Edelssen, Professor of Surgery in the University of Hamburg (specially reported by our own correspondent) on "The Medicinal and Dietetic Treatment of Catarrhs of the Bladder and Kidneys."*

ORIGINAL PAPERS.

SOME NOTES ON FAMILY DISEASES. (*a*)

By T. K. MONRO, M.A., M.D., F.F.P.S.G.,

Physician to the Glasgow Royal Infirmary, and Professor of Medicine in St. Mungo's College.

(Concluded.)

The doctrine of premature decay was long ago applied in one form or another to explain the onset of some of the most common diseases. Thus in the case of cancer no satisfactory theory has yet been devised; different theories seem to suit different cases. But it has been supposed that each tissue is to a certain extent controlled as regards its powers of multiplication by the other tissues which happen to be its neighbours. Thus in the case of a muscle, when the muscular fibres waste, the interstitial tissue tends to increase, and a similar change takes place when nerve tracts degenerate. So when cancer develops in the tongue or stomach, the overgrowth of epithelium has been attributed to diminished opposing power of the sub-epithelial tissues. This obviously is a very partial explanation, but experience suggests that the connective tissues are most vigorous in early life, the period when sarcoma is most common, and that they become senile after 40 or 45. They can then be easily invaded by the epithelial elements, which retain much of their vigour till twenty years later in the life of the individual man or woman. Cancer is well known as a family and hereditary disease; as in the case of Napoleon the First, who, like his brother and two of his sisters, as well as his father, died of cancer of the stomach.

I remember the day when phthisis pulmonalis—consumption or wasting of the body, associated with disease of the lungs—was regarded as a decline of the body generally, in which the lungs were the first part to show distinct signs of disintegration. Hereditary tendency was one of the principal causes recognised at the time, just as infection is now. Both factors are of importance, the soil and the seed. I

(*a*) Presidential address delivered to the Glasgow Southern Medical Society on October 4th, 1906. Illustrative cases and photographs were exhibited.

recently examined a man of 44, who had been suffering from phthisis for 2½ years. "All the family," he remarked, "died of consumption"; his father at 45, his mother at 42 or 45, his sister at 35, his two brothers at 20 and 16, and also two maternal aunts. One might be disposed to say that this was a clear case of infection. But the man left Britain at the age of 18, 26 years ago, and did not return till a couple of months ago, or more than two years after he became ill. His people remained here all along. He had malarial fever 20 years before the present illness, but thereafter he enjoyed very good health till about 2½ years ago. His parents died of phthisis in their fifth decade, and here he is at the same age with the same disease. The inference appears to be that in this family the resisting power of the lungs to tuberculosis was below normal, and perhaps also that it diminished further in the two decades following the completion of adolescence.

It will be seen that several kinds of disease are almost necessarily mingled in any list such as that which I have brought before you:—

(1) There are *family diseases* in the strict sense of the expression; diseases which occur among the members of one family, brothers or sisters, or both, in one generation. These are the primary subject of this paper, and are best represented by the premature degenerations of which I have spoken. They involve certain groups of muscles, certain systems of nerve-cells and fibres, the skin or the retina. The tissues in question are apparently normal at birth and for some time afterwards, but they decay before the rest of the body decays, and often before the rest of the body has reached maturity. Muscular dystrophy, Friedreich's disease, and retinitis pigmentosa belong to this category.

(2) There are *hereditary diseases*, not in the sense in which we speak of inherited syphilis, where an infection is derived by an infant from its parent, but in the sense that they are due to a tendency to developmental defect which is passed on from one generation to another.

The first and second classes are scarcely separable from one another in practice, since so many of their members belong to both. Nevertheless, several diseases or abnormalities which have been mentioned (*e.g.*, xeroderma pigmentosa) show the family tendency very strongly and the hereditary tendency but feebly.

The congenital deafness which leads to mutism is also much more a family than a hereditary affection.

(3) There are *congenital abnormalities of structure* (coloboma iridis, harelip, supernumerary digits, &c.) which are not morbid processes, but abnormal facts already accomplished at the birth of the individual. They are presumably due to arrested development or fission of some embryonic part. We may, perhaps, assume some definite anatomical basis for Daltonism or colour-blindness, and range this abnormality in the class we are now dealing with. Daltonism, like the more obvious structural defects I have mentioned, presents both the family and the hereditary tendency, and may, like so many more of the abnormal conditions and tendencies under consideration, illustrate the phenomenon of transmission to the males through the unaffected females.

(4) There are certain diseases in the sense of *abnormalities of function* (*e.g.*, of metabolism and of muscular movement) which may present a family tendency. In this group there are alkaptonuria, cystinuria, hereditary and family tremor, and Thomsen's disease. If gout and diabetes ("the gout of the carbo-hydrate eater") are not allowed to have any anatomical basis, and are therefore excluded from the first and second classes, then they find their place in the fourth class.

Now, while it is impossible to make a perfectly satisfactory classification of all these diseases or abnormalities, the fact forces itself upon us that, in gravity, they are widely different from one another. Take, for instance, diabetes, or pseudo-hypertrophic paralysis, as situated at one end of the series. If a boy suffers from either of these diseases, he is not likely to live to maturity. At the other end of the series we have such abnormalities or freaks as polydactylism, ichthyosis, and alkaptonuria, which involve no danger to life. The hæmorrhagic diathesis involves grave risks to the life of the sufferers, since only 40 per cent. reach their eighth year, and only 11 per cent. reach the age of 22. It makes marriage most undesirable in the case of those who may transmit the tendency. Some of these diseases render life insurance difficult or impossible. In countries where the succession to titles and estates can take place only through the male line, a disease assumes special importance if it threatens to cut off all the males of a family before they reach maturity or become marriageable. Colour-blindness demands careful consideration in its relation to signalling and the safety of travellers by land and sea. Such diseases as severe ichthyosis make men more or less social outcasts, while other flaws amount simply to slight deformities of person, or to inconveniences, or perhaps not even to so much.

It cannot be said that any definite law either explains or sums up the facts we know with regard to these family or hereditary diseases, or abnormalities of structure or function. Nevertheless, certain well-defined tendencies can be recognised, which force themselves on the attention of the student of the subject, though they take him only a little way towards the solution of the question with which he has to deal. Some of these tendencies we may now note.

(1) The abnormality often shows a tendency to keep to one sex in a family, and this may be seen in successive generations of that family. For instance, colour-bindness is far more common in males than in females; the proportion is perhaps 20 to 1. Yet if it happens to begin with a female in a family, it may confine itself to the female sex throughout several generations of that family. Again, a man in whose family there is a tendency to a certain abnormality among the one sex may marry a woman belonging to a family in which there is a tendency to defect among the other sex, the result of the union being that among their descendants both morbid tendencies may be met with, each, however, keeping to the original sex.

(2) Some of these diseases show a strong preference for one sex, commonly the male sex; while others are equally common in both sexes. Among the former are colour-blindness and the pseudo-hypertrophic variety of muscular dystrophy; whilst among the latter are ichthyosis and the two other types of muscular dystrophy.

(3) Some of these diseases which attack chiefly the males are transmitted mainly by the females, and yet these famales do not themselves suffer. This is not accounted for by the fact that the males are cut off before reaching marriageable age, since these diseases do not all shorten life. Hæmophilia furnishes us with one of the best illustrations of this third tendency, and others are supplied by pseudo-hypertrophic paralysis and Leber's atrophy. While colour-blindness may pass directly from father to son, it may also pass from the father through an unaffected daughter to her sons. Obviously, if no males happen to be affected in the second generation (*e.g.*, through there being no males in the family), we may see the disease skipping over a generation, since the females of the second generation act simply as transmittors or conductors.

The tendency so often shown by one or another of these diseases to confine itself to one sex in a given family is an interesting subject for comment. The doctrine of the correlation of parts was one of Cuvier's greatest contributions to the science of morphology. Thus the absence of gills in the vertebrate embryo is associated with the occurrence of the allantois, and the presence of gills with the absence of that fœtal membrane. Animals which ruminate have a cloven hoof. Ungulates which have horns have no upper canine tooth. Darwin called attention to what he called "correlated variation," as observed among varieties belonging to a given species. Breeders, he says, believe that long limbs are usually accompanied by an elongated head. Male cats which are perfectly white and have blue eyes are deaf. White sheep and

pigs are injured by certain plants, whilst dark-coloured individuals escape. Thus Darwin tells how certain farmers in Virginia always selected the black pigs of a litter for raising, because these only had a good chance of living. The pigs ate the paint-root, and this caused the hoofs of all but the black varieties to drop off. Hairless dogs, again, have imperfect teeth. White, yellow, and dun-coloured pigeons are almost naked at birth, whereas those with other colours have a good clothing of down. The tusks and bristles of the boar vary in degree of development along with one another. And other similar instances might be quoted to illustrate the correlation of organs, and the way in which the different parts of the body are intimately connected as members of an organic unity.

This correlation is not constant in the diseases we have been considering, but it is sufficiently striking. Hæmophilia is associated with the organs and attributes of the male sex in 13 cases out of 14, and in colour-blindness the disproportion between the sexes is still greater. It is scarcely credible that nature, so lavish in producing variations, is unable to produce female hæmophilics. Nowhere, I think, does she show her marvellous resource more strikingly than in the power with which she has endowed the living body to produce anti-substances. We introduce a toxin into the organism, and we find molecules of the corresponding anti-toxin already existing in the organism, which, moreover, proceeds to produce more of that same anti-toxin. If we inject a bacterium of any kind into the body, not only does the latter produce an anti-bacterial substance corresponding to that particular species of bacterium, but it seems to have a small quantity of it naturally present in its tissues or fluids, ready in wait, as it were, for a possible attack by the particular species of bacterium. If we introduce blood corpuscles from some other kind of animal, or renal cells, or any other kind of cell, or cell-product, in every case the animal body appears to already possess a certain amount of the specific anti-substance, and this at proceeds forthwith to produce in increased quantity. When we consider the number of the different kinds of microbes, toxins, and foreign cells that may be introduced into the body, the molecular constitution of the latter is seen to be amazingly complex. We can scarcely suppose, then, that nature is unable to produce female hæmophilics if she wishes. Wherein, then, lies the relation between the development of the structures peculiar to the male and the imperfect development of the blood-vascular system in the hæmophilic, or the imperfect development of the colour sense in one who is congenitally colour-blind? This question still awaits its answer.

Some family diseases, among which may be named retinitis pigmentosa and congenital deaf-mutism, have been regarded as a result of blood relationship in the parents of the sufferers. With regard to alkaptonuria, Garrod found that 60 per cent. of the cases were children of parents who were first cousins. Now it is pretty thoroughly established that the closest intermarriage which occurs in mankind is not of itself capable of inducing defects in the offspring. On the other hand, any tendency to defect or disease is naturally much intensified in the offspring of consanguineous marriages. And this defect apparently may be in function as well as in structure. In alkaptonuria, the defect is in the katabolism of proteid matter, whether of the food or of the tissues; in albinism, the defect is in the production of the melanin group of pigments.

Mr. Bateson suggested, some years ago, that the occurrence of alkaptonuria might be explained by Mendel's law of heredity. According to this law, when two germinal cells or gametes unite which have mutually exclusive characters (*e.g.*, black and white), the resulting cell, or zygote, possesses—not a character intermediate between those of its parent cells or gametes, but—both characters. One of these, however, is "dominant" or self-assertive, whilst the other is "recessive," or so inconspicuous as not to be directly recognisable. If, in a future generation, two gametes unite which happen to possess the same recessive character, the latter may reveal itself—the recessive character displacing the dominant. The marriage of cousins is obviously an event which is likely to promote the meeting of such similar gametes. But if a man receives the tendency to a recessive character such as alkaptonuria from his father, his marriage with a maternal cousin is no more likely to produce alkaptonuria in his son than his marriage with any one who is not related to him. In his case, it would be marriage with a paternal cousin which would increase the chance of alkaptonuria in his offspring. In other words, as Garrod puts it, it is not the mating of cousins, but the mating of stocks, that develops alkaptonuria. Whether the Mendelian theory is useful here or not, it is quite in accord with what I have mentioned as the best modern teaching, viz, that the appearance of abnormalities in the children of blood relations is to be attributed, not to consanguinity in itself, but to the heightening of abnormal tendencies which the consanguinity is apt to involve.

The diseases I have touched on in the latter part of this paper are comparable to the variations, or sports, which occur from time to time among animals and plants, either in a state of nature or under domestication. After the observer has become familiar with thousands of normal specimens, he comes across an individual in which a part or organ presents some abnormality of structure, or in which a function is carried out in some abnormal fashion. In such cases, the endurance of the abnormal structure, or the energy of the abnormal function, may be all that could be desired. On the other hand, the diseases dealt with in the earlier part of the paper are characterised by a deficiency in the durability of the tissue or function concerned. Even there, however, it may be supposed that this premature decay or exhaustion has a basis in, and is evidence of the existence of, some natural sport or variation.

As to the original cause of these variations, it may be said that at present we know nothing. It is quite likely that for their elucidation, not simply fresh workers, but fresh methods will be necessary. Modern researches on immunity have sufficed to show how infinitely complicated must be the molecular structure of the living cell; but it is quite conceivable that some instrument of analysis may be invented which will interpret to us the arrangement of molecules in the cell, just as the spectrum has revealed the chemistry of the sun's atmosphere.

Nevertheless, though we think we know a good deal about the physical basis of life, the problem of life itself is still unsolved. Indeed, it is reasonable to suppose that this is about the very last thing that is likely to be worked out on this earth, by all the ingenuity and industry of the finite human intellect. And if this anticipation is correct, then we cannot but be impressed by the distance at which we still stand from the solution of the question, if we accept the dictum of the illustrious philosopher, that the sum of human knowledge is like a sphere, which, as it grows in size, presents an increasing surface of contact with the ignorance around.

The "Bile Beans" Litigation.

THE case of the notorious "Bile Beans" Manufacturing Company has now been taken to the final Court of Appeal, the House of Lords. It will be remembered that both at the first trial in their action against an Edinburgh chemist, and in the subsequent appeal at the Edinburgh Court of Session, the verdict went against the company. They now seek to reverse these judgments, and have engaged the most eminent counsel on their behalf.

THE INTER-RELATIONSHIP OF CANCER, TUBERCLE, AND VENEREAL DISEASES AND OTHER SOCIAL CALAMITIES. (a)

BY C. B. KEETLEY, F.R.C.S.,
Senior Surgeon to the West London Hospital.

GENTLEMEN,—These addresses, and, still more, abstracts of them, are read by the laity. They therefore afford a special opportunity which is often and rightly utilised. Some of you here present are laymen honouring us with your company, and I am certain that no one desires this afternoon to hear anything like a clinical or systematic lecture. I have therefore chosen to deal with questions which ought to interest every intelligent and educated person. It has been said that "every man at 40 is either a fool or a physician." A very small proportion of people at 40, or any other age, are physicians—the author of the saying was not one himself. I hope he was wiser than his aphorism. The less the public fancy themselves to be physicians the better. It is, however, their duty to try to be practical hygienists, and they are deeply concerned with the problems I now propose to touch upon.

The strong general interrelationship of these great questions has, so far as I know, not hitherto been dealt with. Isolated connections are, of course, familiar, such as that of alcoholism with tubercle; but these problems form a series of interlocking chains. To cut one is to help to untie others, and without attacking all it will be scarcely possible to conquer any completely.

West London adults, incapacitated from earning their living by chronic tuberculosis, sometimes sink to reside in such places as Notting Dale. A family driven by ill-health and poverty into this district grows up amid surroundings of crime, idleness, and vice almost unmatched elsewhere in London. The boys are in danger of growing up to drink and loaf, perhaps to steal, the girls to drink and to practice prostitution. Alcohol, poverty, dirt, and the actual presence of the very focus of tuberculous infection which sank the parent into the district, lead to more tubercle, and so the chain winds on.

But things need not be nearly so bad as that, and may yet produce results which differ only in degree. A single tuberculous child, properly treated, is a strain on the resources of either the parents themselves or of the philanthropic. The means even of a hospital like this are weighed down, sometimes almost to breaking, by the strain of such cases, so numerous are they. The funds of all the general hospitals are ground between an upper millstone of tubercle and a lower millstone of the accidents caused by drink. And when a tuberculous child is looked after at home imperfectly it imperils the health even of its parents, and, through that, their monetary and social position. In short, tubercle tends to impoverish and degrade the family, and thus leads to drink, immorality, venereal disease, and physical degeneracy.

Cancer, by destroying the wage-earning capacity of the parent, may result in misfortunes to the children similar to those produced by tubercle; and by killing the mother at an age when her female children particularly need a mother's watchful protection, endangers their character. In these ways cancer tends to the increase of poverty, immorality, alcoholism, and the venereal diseases.

The venereal diseases, by producing chronic ulcerations and old scars, pave the way for cancer. In another curious but well-known manner they interfere with and delay the correct surgical treatment of malignant growths. Owing to the prevalence of syphilis, and the horrible character of operations for cancer of the tongue and neighbouring parts, much valuable time is constantly being lost in giving antisyphilitic treatment to cases which prove to be really malignant.

Through the facial disfigurement and through the defects of the special senses which both acquired and congenital syphilis cause, and through repeated relapses, the choice of occupation and the ability to persevere in it are often greatly diminished; while, if the sufferer be a female, her value in the marriage market is reduced, and she thus tends to sink in society. Chronic gonorrhœa in both the male and the female is a great cause of domestic unhappiness, of quarrels, separations, and consequently more immorality. When contracted before or soon after marriage it is one of the principal factors in lowering the birth-rate; when contracted after the advent of a family, it leads to not a few separations, and the support of two separate establishments impoverishes any family not rich. Of the disease-producing power of poverty it is needless to say more.

By forgetting, or at least ignoring, the reaction of venereal diseases in producing and keeping up immorality, I am afraid the good men and devoted women who attempt rescue work among the fallen waste a great deal of their means.

Roughly speaking, all prostitutes are diseased, and, being physically incurable, are, for that reason, morally only half curable. It is not the old prostitute who is specially likely to be infected. Infection occurs soon after the poor things come on the town, and sometimes before. The men who infect them, though often merely ignorant and thoughtless, are generally, I believe, the hardened sensualists. They naturally seek out the young prostitute. Imperfect morality is very widespread, but I believe that the great majority of public women are infected by a comparatively small number of diseased men.

A rescued woman, after a period of probation and of submission to good moral influence, is often placed out as a domestic servant. Perhaps she marries the baker's boy, and I suppose her rescuers rejoice. But what is she still? Unsound, childless, disappointed, hysterical, and most likely with a taste for intoxicants. What a prospect for both the husband and the wife!

Possibly the so-called "rescue" of fallen women conducted after this fashion does little else than make room for the fall of a hitherto healthy and comparatively virtuous one.

People who busy themselves in rescue work should feel some responsibility for seeing that the poor women are rescuable. They should not be eager to obstruct practical efforts to prevent the spread of venereal disease. I believe I recognise fully the good which religion has done, is doing, and may be expected to do in these matters; but, by itself, its results are very imperfect. Surely, after nearly 2,000 years, the firmest believers might acknowledge this, and be less jealous, less clamant, and less self-opinionated when science trys to assist. But these questions are very delicate. They are ice almost too thin to tread on in the presence of a civilisation which makes itself hideous by the clothes of its males and bankrupt by the dress of its females, and which bows deferentially to any cant masquerading in the name of "Conscience."

On the question of alcoholism, I go as far as Sir Frederick Treves and Sir Victor Horsley. I have done so for many years, and rejoice that they have spoken out. Publicans and their employés suffer out of due proportion from tuberculosis, and from other diseases too, for the matter of that. Perhaps the old student of St. Bartholomew's who is the most famous, is not Harvey, but John Keats, that young poet who in half the domain of poetry stands alone as the equal of Shakespeare. He died at an early age of rapidly progressing tuberculosis. Hear what his friend Hayden said of him:—"Once for six weeks he was hardly ever sober." (Matthew Arnold, "Essays in Criticism," 2nd series, 1891, p. 101).

An old friend of mine used to say that a man might be immoral without being drunken, but not drunken without being immoral. Further, the drunkard is dirty and careless of his person. In this manner the door is opened to other infectious diseases besides tubercle; and the dirty and otherwise neglected home of the drinking woman tends to increased mortality, depreciated health, and the physical degeneracy of her children. Lastly, alcohol, sooner or later, magnifies the weakness of intellect which causes people to resist

(a) An address delivered at the opening of the session of the West London Post-Graduate College, October 10th, 1906.

hygienic reform, and turns it into crass, obstinate, pig-headed stupidity.

And now, what is to be said about physical degeneracy as the first link in an evil chain? It is, of course, often the last. The small, feeble person with flabby muscles, a weak face, open mouth, defective voice, and imperfect special senses, is seriously handicapped in the battle of life. He is ineligible for many positions, he is rejected by the public services, and looked at askance by private employers. He descends in the social scale. He falls in spite of himself into the company of other unfortunates, such as the tuberculous, the alcoholic, and the immoral, and is influenced thereby to his detriment. Mental and physical inferiority tell very hardly on the female sex. The female dwarf on whom Cæsarian section was performed three times for the extraction of illegitimate children would have had probably a respectable history had she not been a degenerate.

There remains another great question of the day, that of the low birth-rate. It is the custom to attribute this wholly to the wilful use of preventives. I think that is too narrow a view to take. Meddlesome and septic midwifery and gynæcology have something to do with it. The great majority of nurses, and not a few medical men, have still no sufficient grasp of aseptic practice either in midwifery or anything else. It is true that years ago things, in the matter of asepticity, were as bad as, or worse than, they are now; but midwifery and gynæcology were much less active and less interfering, especially in country practices. I don't think the country doctor whose pupil I was used the forceps once in three hundred cases. He rarely lost a patient. It is absurd and libelous to suppose that soap and hot water and clean towels were not known and used by decent accoucheurs and even nurses in those days, though it is true they were not used with scientific knowledge and thoroughness. But are they, as a rule, so used now? Is there efficiency in hurried dips in cold antiseptic solutions often of vague strength.

However, I do not wish to make out ourselves and our nurses to be moral degenerates.

The influence of gonorrhœal infection on the birth-rate has already been referred to, and there is also that of syphilis. The former is well known to be the cause of some of the one-child marriages. The only child is, of course, apt to be badly brought up, to be egotistical, and not properly taught the practice of self-control. As it grows up it is fortunate if, for these reasons, it does not set the ball of evil rolling by becoming, if not alcoholic and immoral, at least ill-regulated, undisciplined, and an active cause of disease in itself and others.

In short, all the evils we have dealt with are relations and allies which, in the main, back each other up, and tend to reproduce one another, or at least to help in such reproduction—tubercle, venereal diseases, cancer, alcoholism, poverty, bad housing, physical degeneracy, a low birth-rate, and immorality.

I am well aware that the current of evil is not an absolutely smooth one, always flowing in the same direction. The only child or the small family may be better left or better educated than a child of a large family. But is the final result found to be better? I doubt it. My friend whom I quoted above, and who had no private fortune, has twelve children. All are doing well, and getting from him and their most excellent mother better starts in life than he had himself. Large families do all right when their individual components are willing to go where they are wanted, and to do the kind of work other people want of them; and they are so willing when properly brought up, when healthy, and when free from snobbery.

Even tubercle, which is often a great producer of beauty, has got many a clear-skinned, long-lashed victim a rich and even a good husband.

But such little back washes and returning eddies are not to be seriously set against the main current, whose black course is to perdition.

And now to draw a moral. The first essential is to grasp the idea of the all-pervading influence of the microbe. For rough, practical purposes, and the public cannot be expected to refine, all disease may be regarded as of microbic origin. When we say that a man killed himself by dissipation, or even by drink, or that he died of accidental injury, nine times out of ten the dissipation, the drink, and the trauma would not have been fatal but for the intervention of the microbe. The next thing to remember is that all these microbes have an ancestry—in other words, that we get, practically speaking, all our diseases, either directly or indirectly, from one another. It is time we ceased to blind ourselves and the public by limiting the term "infectious diseases" to narrow classes. A rapid gastric cancer which kills in three months is as much an acute or sub-acute infectious disease as any fever which proves fatal in the same time.

The prophylaxis of all disease lies mainly in sterilisation of food, in limitation of intercourse, in general cleanliness, and in special aseptic and antiseptic precautions, adopted stringently and at the right times, against special risks.

It is now obvious where morality comes into play in the prevention of all kinds of disease, not merely of the venereal affections. Take an extreme case, the ordinary low-class brothel. What a pest-house it must be! Police observation shows that seventy or eighty couples will frequent such a house in one week. Think of its general dirtiness, its closed and curtained windows, its rarely-washed sheets, its alcoholic and unhealthy habitués. And adults are no more proof to infection than children. Perhaps in the frequent references to immorality in this paper, I am thinking more of promiscuity. As a student of science I am certainly not thinking of marriage lines. But, as a man of the world, I recognise that society—at least, in these times—cannot be made sufficiently moral for hygienic purposes without the help of religion, and I frankly say so, hoping that the pious, in return, will help science, or, at least be a little more careful than some of them have been not to hinder her. There is just now so much to be done, that good and sensible men should work together, whether they agree about dogma or not.

I have not referred to fresh air, abundant water, exercise, light, rest, appropriate feeding, and clothing, because their value is now fairly well recognised. In fact, I think the amount and so-called quality of food as factors in the well-being of the individual and of the race are exaggerated. Healthy and vigorous tribes are found living in various parts of the world on many varieties of food, including the almost exclusively vegetable or animal, fresh fish, stale fish, even exclusively shell-fish, getting their meals with the irregularity of the hunter, and yet doing well, so long as the pathogenic microbe holds aloof.

An address like this is no place for detail. Its object will have been served if it has done a little to prove that the great problems on which it has touched require to be considered together as well as separately if they are to be solved, while at the same time every step towards the solution of one should help to make easier that of the others. And I further wish it to contribute, even if very feebly, to persuade the philanthropist, the priest, and the physician to work together as allies.

THE OUT-PATIENTS' ROOM.

ROYAL EAR HOSPITAL.

Affections of the Throat and Nose.

By R. Lake, M.S., F.R.C.S.

Amongst the out-patients was a young married woman, æt. 25, who chiefly complained of a feeling of thickening in her throat, with weakness of the voice, especially when reading aloud to her invalid father. She had been married about five years, but had no children. Two years ago she had attended another institution with this same condition, when she was told she had a relaxed throat, for which, evidently, the galvanic cautery had then been applied. The patient, a nervous, rather foolish young woman,

seemed to have great difficulty in explaining her sensations, and was rather apt to employ pseudo-medical terms, but by leading questions Mr. Lake was able to elicit the following series of symptoms: (1) that the mouth was frequently dry in the morning, with an unpleasant taste; (2) that there was a large amount of discharge (or phlegm) at the back of the throat, giving a feeling as if it came from the back of the nose; (3) that there was a feeling as if there was a foreign body in the throat, this causing a frequent desire to swallow; (4) that the voice was frequently weak, though never entirely lost; and (5) that the patient suffered from attacks of flatulent dyspepsia. On examination the following points were brought to light: In the nose the inferior turbinate bodies showed marked hypertrophic rhinitis; there was a large spur on the left side of the nasal septum running backwards well into the vomer and reaching across to the outer wall of the nasal cavity; the mucous membrane of the vault of the naso-pharynx was red and congested, the uvula somewhat enlarged or thickened, with a moderate amount of granular pharyngitis. The laryngoscope revealed further that the adenoid tissue at the base of the tongue was so hypertrophied as to bring it into constant apposition with the edge of the epiglottis. Mr. Lake pointed out that a series of symptoms which were accounted for by the departures from the normal had been demonstrated as present in this case; thus the dry and rather foul mouth in the morning was accounted for by the nasal obstruction due to the hypertrophic rhinitis and the spur; again, the large amount of phlegm at the back of the throat was due to nasal obstruction, causing hypersecretion in the naso-pharynx, as was evidenced by the hyperæmic state of the pharyngeal vault; the subjective sensation described by the patient as a feeling of a foreign body in the throat was due to the fact that the epiglottis was brought into constant and unnatural contact with the base of the tongue; the swelling of the latter organ was due to its being constantly irritated by mucus passing over it *vid* the uvula, which acted as a gargoyle from the naso-pharynx, the weakness of the voice, again, was a reflex effect due to the unnatural relationship of the epiglottis and the lingual tissues, whilst the dyspepsia was probably originally caused, but certainly aggravated and kept up, by the constant ingestion of mucus. Thus these conditions, Mr. Lake said, really produced a good example of a well-known vicious circle, all the symptoms coming in sequence, the ones behind depending on the ones in front, and all being influenced for worse by the reduction of the vital energies consequent on faulty nutrition. With regard to the treatment, Mr. Lake said that it must be obvious here, as elsewhere in medicine, that certain of the conditions complained of were only symptoms, and whilst efforts directed to their relief might be temporarily successful, no permanent good results could accrue by such methods. There were, therefore, two courses open: the first, more logical and most radical, would be to commence with the earliest source of the trouble—in this instance the nasal passages—remove the spur, reduce the hypertrophic rhinitis to a normal condition; in fact, treat the nose in such a manner that the nasal passages should become equal and sufficient to the needs of the body; from this point the two treatments were the same, and would consist in a frequent painting of the naso-pharynx with Mandl's weaker solution, not omitting the employment of a nasal douche or spray; the use of an astringent gargle to assist in removing the congestion at the base of the tongue, and at the same time the dyspepsia must receive adequate treatment. If these methods were not sufficient to obtain relief from the sensation of a foreign body in the throat and to relieve the weakness of the voice, direct surgical measures would have to be undertaken, consisting in removal of a sufficient amount of the lingual tonsil by means of punch forceps, or by the galvano-cautery and knife.

Influenza has been recently reported on the increase in various parts of the United Kingdom.

OPERATING THEATRES.

CANCER HOSPITAL.

ABDOMINAL HYSTERECTOMY FOR CANCER OF THE UTERUS.—Mr. CHARLES RYALL operated on a woman æt. 45, who had been admitted suffering from hæmorrhage. She stated that she was quite well up to three months ago, the periods being regular. Since then she noticed a considerable loss at the menstrual periods, with intra-menstrual irregular hæmorrhages and some watery discharge of an offensive nature. On examination the uterus was found enlarged, but perfectly movable, the os was patulous, and, on passing the sound bleeding readily occurred, and some small fragments of friable material came away. Carcinoma of the fundus was diagnosed, and as there was no evidence of extension of the disease to other parts, abdominal hysterectomy was recommended. The abdomen was opened in the middle line, the patient being placed in the Trendelenburg position, and a Doyen's abdominal retractor was fixed in the lower angle of the wound. The peritoneum was divided across that portion of the broad ligament external to the ovaries, and the ovarian vessels thus secured; the peritoneal incision was then carried inwards, passing in front above the base of the broad ligament, and crossing the uterus opposite the vesical uterine reflection. An incision was also made through the peritoneum behind both broad ligaments and extending to the cervix. Each broad ligament was thus dissected away from its attachments, care being taken not to wound the ureters, which were carefully dissected out where they ran through the broad ligaments. The uterine arteries were searched for and found and secured where they arose from the external iliacs. The bladder was then dissected off the anterior surface of the uterus and the upper portion of the vagina. The latter was then incised in front and the incision carried round the vagina, thus liberating the uterus. There was no bleeding, but some slight oozing occurred from the vaginal walls, which was checked by bringing the latter together by sutures, thus shutting off the vagina. There were no enlarged glands to be found anywhere in the pelvis, so the pelvic floor was completed by carefully suturing the divided peritoneum from one side of the pelvis to the other. The abdominal wound was closed in three layers. Mr. Ryall said he did not think that vaginal hysterectomy was ever performed nowadays by those who were accustomed to deal with cancer, though it had been a useful operation before the technique of abdominal hysterectomy had been perfected. The abdominal route, he thought, was undoubtedly the proper way to grapple with such a disease. The vessels were more easily tied, and wider excision could be carried out, including that of the surrounding cellular tissue, the glands, and the upper part of the vagina; besides, it was more satisfactory to the surgeon to feel he had done everything possible for his patient. In an extensive case, it was quite impossible, he considered, to operate by the vagina owing to the necessity of dissecting out and protecting the ureter. The latter was very easily found attached to the reflected peritoneum, and could be followed where it entered the base of the broad ligament, crossed the uterine artery, and entered the bladder; in all operations it was important, he remarked, to dissect it clear of the surrounding tissue as little as possible owing to the danger of cutting off its blood supply, and so causing consequent necrosis, but, ortunately, it was only that portion in the base of the. broad ligament that need be interfered with. Mr

Ryall said he believed in operating on even extensive cases if there was the least chance of getting the disease away, as operating for malignant disease often gave surprising results. There were many cases, he pointed out, in which it was impossible to settle the possibility of operation without abdominal exploration. With regard to Doyen's retractor, he found it of great service in all pelvic operations, as it kept open the abdominal wound and thus facilitated any suturing in the pelvis.

The patient made un uninterrupted recovery.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 9TH, 1906.

The President, Mr. CLUTTON, in the Chair.

Dr. E. DIVER read a paper entitled

A PRINCIPLE OF TREATMENT SUGGESTED FOR SOME UNTOWARD FRACTURES, ESPECIALLY OF THE FEMUR.

The treatment suggested varied from that generally in vogue, in that where good apposition is not attainable effort is directed to gaining *contact* merely of some portion of the broken ends of the bone, regardless of the contour of the limb, until callus is beginning to fix the fracture, and then to seeking restoration of the normal outline by movements alternating with periods of rest, much as in a case of tenotomy. So that callus as it is hardening shall yield as the surgeon's manipulations change the relative position of the fragments, until the limb is as far as possible in symmetry with the other. In some cases the effect of muscular action would be to aid in maintaining the fragments in the position the surgeon might place them in. The principle of treatment was similar to that governing the treatment of club foot.

Mr. CHARTERS SYMONDS read notes of a case of

MULTIPLE STRICTURE OF SMALL INTESTINE, PROBABLY OF TUBERCULAR ORIGIN.

G. W., æt. 43, was admitted into Guy's Hospital September, 1893. Since a boy subject to abdominal pain. Married at 20, and his wife said he had one or two attacks of pain a year. They occurred at night, and disappeared by the next day. He was first seen on August 30th, 1899, and said that the attacks had been more frequent the last three years. There had been almost constant pain for the last three months. The abdomen was big, coils of small gut could be seen, there was loud gurgling, and a marked sound as of fluid passing a narrow orifice. He was very thin indeed, but no signs of tuberculosis were ever found. On September 5, 1899, the abdomen was opened, and resection with end-to-end anastomosis was carried out. The portion removed was 15 inches long, and showed a thickened and dilated length of bowel, with a stricture at either end. The dilated portion was the size and shape of a small stomach, and about 12 inches in length. The strictures were 1½ inches long. The man has had no return of symptoms, and is at present in perfect health. Reference was also made to a similar case that occurred in a child.

Mr. F. J. STEWARD narrated a similar case in a man of 37, who was admitted into Guy's Hospital with symptoms as of duodenal ulcer. There was bad pain behind the upper part of the right rectus. At the operation two strictures were found, with no evidence of tuberculosis. Resection was performed successfully.

Mr. A. E. J. BARKER suggested typhoid as a possible cause of the strictures. He had seen similar cases occurring after strangulated hernia. He laid stress on the accumulating evidence that shows the importance of excising larger sections of intestine than we were wont to; there was little or no increase in shock with the more extensive operations. He dealt fully with the problems of technique, and suggested that lateral anastomosis was preferable to end-to-end joining when the lumen of one gut was so much smaller than that of the other as to necessitate a tuck.

Mr. CHARTER SYMONDS replied.

Mr. EDRED M. CORNER, in a paper upon

ROTATORY SUBLUXATION OF THE ATLAS,

drew attention to those cases in which, as the result of violence such as a sudden twist, the head becomes fixed in a rotated position. This, he concluded, was the result of the locking together of the forwardly displaced side of the atlas on the axis by muscular action. The position and fixation of the atlas can be demonstrated clinically by the position of its transverse processes, and by the movements which the head can perform. The latter are somewhat difficult to understand, and were demonstrated by means of diagrams. Cases were quoted in support of these statements. A skiagraph was mainly of use to demonstrate the absence of complicating injuries, such as a fracture of the odontoid process or of the anterior arch of the atlas. If such additional fractures are excluded, an anæsthetic should be administered slowly. If muscular relaxation is induced, the head would probably roll back into its proper position, so that when the patient comes round, full movements of the head are restored. These accidents have usually been attributed to the displacement of the part of the splenius muscle or to the slipping of one of the deep tendons over the transverse process of a vertebra.

Mr. STEWARD asked whether subluxation might occur with intact ligaments.

Mr. CORNER said they were so loose that the occurrence was certainly possible, as he had often demonstrated on the cadaver.

Mr. JACKSON CLARKE read a paper on

CONGENITAL DEFORMITY OF THE SPINE.

The patient, a boy, æt. 4, had the head fixed from birth so that the chin was close to the sternum, and there was no movement in the cervical spine, either of flexion and extension or rotation. The general appearance recalled cases of anencephaly. The boy's mind appeared to be normal. Operative treatment, followed by massage, gave the boy a short neck with all the natural movements. Skiagraphs showed extensive abnormalities in the form of the bones in the upper dorsal and cervical regions, and a cervical rib was present on each side.

The PRESIDENT agreed with Mr. Clarke that the origin of the deformity might have been an anterior spina bifida in the cervical region.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

President: J. F. O'CARROLL, F.R.C.P.I. Sectional Secretary: Professor WHITE, R.C.S.

MEETING HELD FRIDAY, OCTOBER 26TH, 1906.

Dr. ARTHUR H. BENSON in the Chair.

PANCREATITIS.

Dr. EARL exhibited a pancreas, omentum, and portion of mesentery from a case of pancreatitis. The two latter showed well marked and extensive fat necrosis.

Dr. W. G. HARVEY exhibited specimens, and stated that in his case the patient, aged about sixty, and a fairly stout man, had been complaining of vague pains in the abdomen for four or five days before coming into hospital. He had been drinking heavily, and one morning on going into a public-house fell unconscious, and was brought to the Adelaide Hospital. On admission he was quite unconscious and breathing heavily. He died in a few minutes. Post-mortem showed (1) fat necrosis over the abdominal and mesenteric fat; (2) pancreas enlarged, swollen, dark, friable, and on section showed several large hæmorrhages; (3) gall bladder somewhat distended, but no gallstones. Microscopically the pancreas showed necrotic and hæmorrhagic areas.

Dr. MCWEENEY said it would have been interesting

to learn exactly how it was that, in the specimen shown by Dr. Earl, such a relatively small amount of pancreatic destruction could have resulted in such very extensive fat necrosis. He would also have been glad to know why the fat-splitting ferment exercised its effects upon certain small and isolated areas somewhat removed from the pancreas, while it appeared to spare areas in immediate contact with the pancreas. In regard to Dr. Harvey's specimen, he (Dr. McWeeney) was under the impression that the hæmorrhagic pancreatitis was a microbic affection; but the surgeons present would be able to say whether such hæmorrhagic cases ever went on to genuine suppuration.

Dr. PARSONS expressed regret that, owing to the brief time during which the two cases were under clinical observation, it would hardly be possible to obtain answers to all the questions to which they gave rise. He would have liked to know when the cases had been first recognised as pancreatitis, and whether any sugar or Cammidge's crystals were found in the urine. Such crystals might have considerable importance in the diagnosis of pancreatitis—a matter always of great difficulty.

Dr. EARL, in reply, said he had little to add to what he had already stated. They had still to find out a good deal more about the subject than they already knew. He had not had an opportunity of examining the patient's urine, as he was operated upon immediately he was admitted to hospital. He would only add, in conclusion, that the ducts were not affected in any way, and there were no gallstones.

Dr. HARVEY, in reply, regretted that, owing to a hurried post-mortem for the Coroner, he had not been able to make a complete bacteriological examination. He had stained a section by Gram's method, but found no organisms.

CARCINOMA OF BREAST, WITH SECONDARY GROWTH IN HUMERUS.

Mr. JAMESON JOHNSTON detailed the history of a carcinoma of breast, with secondary growth in humerus, and showed microscopic slides.

Dr. MCWEENEY said that, while, as a rule, he was able to say right off whether or not a breast tumour, sent for examination, was a cancer, occasionally a difficult case would crop up like the one described by Mr. Johnston. He recounted, in detail, a case exhibiting characteristics which at first sight appeared to be cancer, but which turned out to be a case of interstitial mastitis. He mentioned the case as an example of the difficulty sometimes met with in cases of breast tumours. It had always occurred to him as peculiar that, although breast cancers are so common, he had never seen a case of secondary cancer of the bone diagnosed in hospital or found in the post-mortem room. This was probably because such cases seldom remained in the hospital to the end.

TRICUSPID STENOSIS.

Dr. BOXWELL exhibited a heart showing well-marked tricuspid stenosis, together with lesions of the mitral and aortic valves.

CRYOSCOPIC WORK.

Mr. L. G. GUNN read a short note on cryoscopic work done during the past two years, showing that the information obtained from this method was similar to that obtained by a quantitative analysis of the urine, or the blood, or the accurate reading of the specific gravity, provided the fluid had been deprived of proteids. The method of finding the freezing point was demonstrated by means of Beckmann's apparatus. Mr. Gunn believed that slight alterations in the freezing point of the blood were of far greater importance than considerable alterations in the molecular concentration of the urine. In no case in which normal urine readings were obtained did the kidneys show any functional deficiency after the removal of the other kidney. On the other hand, in two or three cases, patients with only one kidney remained healthy, although the urine showed a molecular concentration considerably below normal.

Dr. MCWEENEY said that he had not been convinced, either by his reading on the subject, or by the communication just made, that the diagnostic advantages to be derived from cryoscopy of the urine would compensate a hard-worked pathologist for the labour involved in working the apparatus which had been exhibited. It was acknowledged that the lowering of the freezing-point was a valuable indication of molecular concentration; but he failed to see the necessity for the method of cryoscopy, when it was always possible for a man—who was clever and patient enough to carry out cryoscopy—to determine accurately the total solids after removal of the colloid constituents, or to take the specific gravity accurately. What applied to urine applied also to the blood; and, as the latter coagulated with considerable activity, he thought it was a difficult matter to saturate a sample with oxygen, as mentioned by the communicator. In his opinion one would have to be pretty sure of his technique in order to draw wide inferences from the delicate data and slight divergences from the normal which were obtained by cryoscopy. He considered that simple methods, such as the taking of the specific gravity, gave just as useful results; and he was glad that the knowledge which he had gained from Dr. Gunn's authoritative statement had not imposed on him any change in his personal practice.

Dr. GUNN, in reply, said he had taken up the subject of cryoscopy, because he believed that by it much might be found out about the condition of the kidneys. The time and labour involved were not very great; two or three readings of half a dozen samples could be taken in an hour; and it was, of course, necessary that the *mean* of two or three should be taken. He did not deny that the specific gravity gave an equally good demonstration of the molecular concentration, but in that method all the albumen in the urine had to be got rid of. He thought the only way to advance knowledge was by trying every method, and the only way to ascertain the value of cryoscopy was by using it.

ULSTER MEDICAL SOCIETY.

THE Opening Meeting of the Session was held in the Medical Institute, Belfast, on Thursday evening, November 1st.

Dr. CALWELL, President, took the chair, and, in a few words, thanked the members for their kindness to him during the past two years, and expressed the pleasure he felt in introducing to them as his successor his old college friend, Dr. David Gaussen.

On Dr. GAUSSEN taking the chair, Mr. ROBERT CAMPBELL moved, and Dr. O'MALLEY seconded, a vote of thanks to Dr. Calwell for his services to the Society as its President during the past two years.

Dr. GAUSSEN then proceeded to deliver his inaugural address. He began by referring to the chief events of medical interest to the members of the Society during the past year—the successful issue of the movement for the better equipment of Queen's College, and its bearing on medical research work, the portrait of Edward Jenner presented to the Society by Sir Otto Jaffe, the honour bestowed on our old fellow-townsman, Sir A. E. Wright, the result of the Darnell case, and, lastly the death of one of our Fellows, Dr. James Lynass. As the subject on which to address the Society, Dr. Gaussen chose "Some Recent Advances in Scientific Medicine, and our Duty Regarding them." These advances were so great that it might seem as if it would soon be impossible to follow all, and that the great class of general practitioners, to which he himself belonged, would cease to exist, and only specialists would survive. But the human body was not a mere collection of machinery, and there was something in man, and might he say more particularly in woman, which was a law unto itself, and with which as medical men we could never deal successfully till we recognised the influence of mind over body. He believed that this complex question of the extent to which the brain

influenced the body, and *vice versa*, was not enough studied, and he looked forward to the future when this influence would be recognised as one of our most valuable therapeutic agents. We have left such things too much to the quack and the charlatan, but we are morally bound to study scientifically all means whereby our patients may be benefited, and medical psychology must not be limited to the study of mental disorders, but extended to the influence of the mind on the body, both the particular body governed by that mind, and other bodies as well. The healing powers of nature must be directed to some extent by the psychic centres, and since we recognise nature as the best physician, and we her humble assistants, should we not consider the possibility of control? In the course of five years study the medical student has not one minute for such subjects; he hoped the day would come when medical psychology would be a compulsory subject for the student. Dr. Gaussen then dealt with the subject of recent introductions of new drugs, our knowledge of them, and the art of prescribing them. The busy practitioner was bewildered by their number, and while many were useless no doubt some were really valuable, but he obtained little help in selecting from them, except the recommendations of financially interested manufacturers. Regarding secret or proprietary remedies, again, the orthodox position was absurdly weak. Some such remedies were undoubtedly valuable, and our patients' welfare should be our first consideration. On preventive medicine, Dr. Gaussen expressed very pronounced opinions, believing that treatment on the lines followed by Wright would be the treatment of the future in many diseases. In spite of the vast possibilities ahead, however, he did not think we need expect to get rid entirely of diseases such as tubercle. For their better prevention nothing would avail so much as the scientific education of the general public, carried out by medical men. He advocated also the instruction of school children in hygiene and the elements of sanitary science, and specially in the means to be taken for the prevention of consumption and infectious diseases.

At the close of his address a cordial vote of thanks was accorded to the new President on the motion of Dr. John Campbell, seconded by Mr. A. B. Mitchell.

It was announced that the annual dinner of the Society would be held in the Institute on Thursday, November 15th. At the close of the meeting tea and coffee were provided by the President.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Clinical Meeting held November 2nd, 1906.

The President, Dr. Leonard Mark, in the Chair.

The following cases were shown:—

Dr. Saunders: Two Cases of Congenital Œdema of the Legs.

Mr. Baldwin: (1) Case of Dislocation of the Hip reduced by open operation. (2) A man, æt. 31, on whom he had performed Excision of the Knee for Tuberculous Disease of long standing.

Mr. Keetley: Two women on whom he had performed the operation of Appendicostomy with satisfactory results.

Mr. Pardoe: (1) Malignant Tumour of the Neck. (2) Abdominal Tumour.

Mr. Cecil Leaf: Cases of Tumour of the Breast.

Dr. Seymour Taylor: Case of Locomotor Ataxia in a woman.

Dr. J. Wallace: A boy, æt. 7, suffering from Lymphadenoma of Glands of Neck.

Mr. Donald Armour: A Case of Tumour of the Scalp.

Dr. Phineas Abraham: Case of Pityriasis Rubra.

THERAPEUTICAL SOCIETY.

A report of proceedings at the last meeting of this Society (sent in officially) having appeared in our columns on November 7th, we are asked to publish the following note in our present issue:—"The Secretary regrets that the reporter of the discussion at the last meeting of this Society was under a misapprehension as to what Sir Lauder Brunton said. Sir Lauder Brunton has had *no* personal experience of the therapeutic uses of preparations of violet leaves."

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 11th, 1906

Treatment of Varicose Veins.

The medical treatment of varicose veins should have a triple aim: Attenuate the existing symptoms, diminish the venous dilatation, prevent grave complications, of which rupture of the vein and elephantiasis (induration) of the skin are the forerunners.

The treatment, says Prof. Robin, should be at first hygienic, comprising hygiene in standing and hygiene in walking.

Patients should avoid as far as possible standing for any length of time; they should either be lying down or walking. As the blood only flows in the veins by muscular contraction, it is better to advise walking, on the condition that it does not cause pain or inconvenience in the legs. All constriction of the veins by garters should be suppressed.

The teguments should be maintained absolutely clear, and the function of the intestine carefully attended to, especially in women, in whom constipation is so frequent. No alcohol nor spiced food should be allowed, and the patients will be enjoined to observe as much as possible a vegetable diet.

The medical treatment will give good results, provided it is persevered in. To stimulate the muscular coats of the veins, the following drops should be ordered, and continued for a long period:—

Tincture of Hamamelis virginica
Tincture of Viburnum prunifolium aa 6 drachms
Six drops in a little water every morning.

To diminish the process of sclerosis, iodide of potassium is a good agent, prescribed in small doses (2 grains) and continued for months.

The local treatment is very important, but rather difficult to get the patients to accept. The limb should be enveloped every night in compresses of lead lotion covered with cotton wadding, oil silk and a flannel bandage.

If this treatment be not accepted, the parts should be coated very lightly each evening with:—

Iodide of potassium	1 dr.
Ergotine	1 dr.
Extract of Nux Vomica	xv. grs.
Benzoate lard	1 oz.

As local mechanical treatment, the use of the elastic stocking would be necessary, but it costs dear, wears out quickly, and is suitable only for persons who are aware of the necessity of keeping it absolutely clean.

For the working classes, Velpeau's elastic band is the ideal; it should be long enough to go from the foot to the inguinal region. Put on in the morning, it is taken off at night. In any case, the elastic stocking is more harmful than beneficial, unless it reaches above the knee.

Besides this passive mechanical treatment, massage should be advised. The hands, coated with vaseline, should be passed lightly over the limb from below upwards for a quarter of an hour, morning and evening. The massage is more efficacious after a bath, however. A bath might be prescribed three times a week; the patient remains half an hour in the bath and then goes to bed. It is at that moment that the massage should be done, and, where possible, by the medical attendant himself.

HÆMATEMESIS.

Frequently gastric hæmorrhage is so abundant that the classic absolute diet is insufficient. Injections of ergotine produce but temporary relief; it is evident that gastric mucuous membrane itself must be treated. Absorbing powders seems to have only a neutralising effect, and without any effect on the hæmorrhage. Small pieces of ice given by the mouth, and the ice bag to the stomach, is good treatment. In case of abundant blood vomiting, Boas tells of having employed with success washing of the stomach with iced water, but that treatment is difficult, if not impossible, in private practice.

The following jelly given by teaspoonfuls has proved very successful in the hands of Prof. Œttinger, of Paris.

Gelatine	1 oz.
Sugar	1 oz.
Syrup of lemon	1 oz.
Water	vj oz.

This jelly is agreeable to take, and does not increase the pain nor the gastric acidity. While the hæmorrhage lasts, two or three injections of serum of six ounces each should be administered, and the treatment will be completed by two enemas of water of the same quantity, to which a few drops of laudanum should be added.

GERMANY.

Berlin, Nov. 11th, 1906.

QUACKERY IN GERMANY.

QUACKERY flourishes here in spite of all efforts to repress it, although these efforts are not few; neither, however, are they without some result. There is a society for the *Bekämpfung* of quackery, or *Kurpfuscherei*, as it is harmoniously called, just as there are societies for the *Bekämpfung* of tuberculosis and cancer. What its numbers are I do not know, but it is known that it is actively engaged in fighting quacks and quackery wherever there is a chance of obtaining a conviction, and in throwing a healthful light over the dark doings of quacks. The official organ of the society is the *Hygienische Blätter*, published by Dr. Carl Reissig, of Hamburg. From the October number of the *Blätter*, we learn that during the past year forty-eight quacks have been prosecuted with success. In a supplement accompanying the monthly report is a tabulated record of the cases that furnishes interesting reading, as it gives along with the name of the offender his (or her) specialty, former occupation, previous punishments (as in the case of No. 1, who had already served a term of seven years in gaol), method of treatment adopted, sentence, and date of time and place. No. 1 was convicted of an offence against decency and sentenced to three years' imprisonment with hard labour; No. 2 to five months' imprisonment for causing bodily injury through culpable negligence; No. 3, for obtaining money under false pretences, one month's imprisonment. A maker of "Kraftpulvern" a director of a theatre, was fined 100 marks for deception. A man named Fauser, styled a "homœopath," who had been frequently punished before, was sentenced in April last at Cologne to nine months' imprisonment for "causing bodily injury through negligence." Friedrich von der Filten, a bone doctor, formerly a non-professional attendant, was fined 500 marks at Cologne for the same cause as the last. The next case is of special interest in view of the notorious Mrs. Eddy's approaching end. The culprit was a lady who was a professional health-prayer (*Gesundbeterin*). She treated cancer of the breast by means of medicaments and prayers, and was sentenced to one month's imprisonment for cheating at Munich in March last. This lady exacted an honorarium of 145 marks. The next was a bad case, and is that of "nature artist." He also had been many times in the house of correction. He treated ulcers of the cornea with inunctions of almond oil, and in the case or which he was convicted the eye of the patient (a boy) burst through the ulcer and the sight was irretrievably lost. He was sentenced to one year's "imprisonment" for causing bodily injury through negligence. The next was a man named Harromer, but who called himself Graf Clairveux, and whose clients were mostly females. His cases were treated with worthless drugs and in so far did no bodily harm. He was convicted as a cheat, however, was fined 1,000 marks, sentenced to three and a half years in the Zuchthaus (House of Correction), eighteen months' "imprisonment," and five years' "deprivation of honour" (*Ehrverlust*). This man had been repeatedly punished for previous offences, so that he was an old offender. Auguste Knopp, the wife of a blacksmith, treated all sorts of diseases. She was sentenced to fourteen days' imprisonment and a fine of 500 marks for cheating. Her mode of procedure was eminently artless, and the very essence of simplicity. She burned broom twigs and, after putting them in water, sprinkled her human and bovine patients with the water. And a brutal magistrate sent her to gaol for this! A gentleman, an expert in teeth, or *Zahnkünstler*, was sentenced to four months' imprisonment for false pretences. His offence was that he extracted sound teeth in order to replace them by his own artificial ones, which, however, were not even of good quality. The next on the list was a swindler of a philosophical turn of mind, and who, evidently as the result of long contemplation and study, articulated his thoughts into words and wrote them down in his diary. As they contain a great deal of wisdom they are worth reproducing. The bright jewel of wisdom is as follows:—"So lange die Toren nicht aus der Welt verschwinden wird unter ihnen stets ein Kluger sein Brot noch finden," which may be freely rendered: "So long as there are fools in the world a clever chap will get his living out of them." He posed as a magnetopath, whatever that may be. He had been many times in gaol. His stock in trade with which his patients were treated was wadding shirts and "magnet water." The offence for which he was sentenced to six months' imprisonment was homicide through criminal negligence.

It may be here mentioned that in Germany there are three grades of punishment by imprisonment. The third or highest grade is that of the "Zuchthaus," which is equivalent to imprisonment with forced or hard labour. The second is simple imprisonment ("Gefängniss"), without the exaction of forced labour, but the prisoner may work if he expresses a desire to do so. The first, or lowest, is not called "imprisonment" at all, but simply "custody," or "detention" (Haft). The shortest term of detention of "Haft" is twenty-four hours, and the longest six weeks. The last offender was sentenced to "Gefängniss." It will be observed that in some sentences the same offender undergoes imprisonment in more than one grade, as, for instance, the man who is sentenced to three and a half years' "Zuchthaus," eighteen months' "Gefängniss," besides a fine, or "Geldstrafe," of 1,000 marks.

The offences for which others were punished were: Frequently the criminal infliction of bodily injury, obtaining money under false pretences (by pretending to treat cases, &c.), the unlicenced sale of drugs, as when a man was fined for selling chloroform and extract of filix mas for tapeworm; indecency under pretence of massage, dishonest mode of life, pretending to set dislocated limbs but failing to do so to the injury of the patient, procuring abortion (one and a half years' "Gefängniss"), falsely assuming a professional title (200 marks and 10 marks); deceiving the public by pretending to cure baldness and using sharp remedies for the purpose. This case is interesting as the offender represented himself to be only a representative or agent of a certain John Craven Burleigh. One city quack professed to cure by "personal magnetism," another by "sympathy" remedies, another by packings and gargling, another treated cancer of the uterus by magnetism, massage, and baths. This offender was let off very easily, only getting one

year's "Gefängniss" for homicide by culpable negligence. Still another, a shoeing smith, treats diseases by "drops and rubbing," and another treats ruptures "homœopathically," but how this is done is not explained. It certainly requires a considerable amount of dexterity to accomplish such a feat. One lady practises by magnetism *and* telepathy. Her current of telepathy she claims reaches 125 German miles. She adds to these wonders the pretensions of a teacher of singing, piano-playing, and dancing. One had discovered the "Fountain of Perpetual Youth," and proceeded at once to exploit it.

The love of the marvellous and the belief in it are, however, ingrained in human nature, and will remain in spite of schools and science. It is very meritorious and laudable, however, to endeavour to light up what is mysterious and dark and to frustrate as much as possible the sinister design of those who would prey on human weaknesses.

AUSTRIA.

Vienna, Nov. 11th, 1906.

GANGRENA PEDIS.

AT the "Geseilschaft," Mcszkowicz showed two cases of Raynaud's disease, and endeavoured to prove that it was possible to locate the site of the morbid changes and thus define exactly the extent of the operation necessary in the event of amputating. The first patient he had experimented on was a waiter, æt. 57, who complained of pain in one of his legs, which caused him to walk with a halt. This soon became intermittent in character, and, as subsequent evidence proved, was due to the narrowing of the lumen of the arteries of the lower extremity, following endarteritis obliterans, or possibly an organised thrombus, either of which would lead to a thickening of the fibrous tissue and intima of the vessel.

The second case was a shoemaker, æt. 37, who had lost the fourth and fifth toes of the left foot five years ago through gangrene. He still complains of pain in the lower extremities.

Moszkowicz here related his experiment of placing an indiarubber band on the upper part of the leg as a tourniquet, and relieving it after five minutes' application. In a normal leg where the circulation is healthy, the flow of blood will commence in the tourniqueted limb immediately the indiarubber band is relieved, but this is quite different where the circulation is interfered with through morbid changes. In Raynaud's disease, the hyperæmia in the thigh is rapid and extends to the patella, but stops suddenly at that point, which stands out in bold relief when compared with the lower part of the leg. In the course of two or three minutes, the hyperæmia slowly invades the toes, passing sluggishly from one toe to the other, till finally it is observed to pass over the points. In the second case of Claudication intermittente, the progression of the hyperæmia was still more sluggish and the demarcation more marked. This symptom, he thought, was an excellent guide for determining the height that the gangrene might rise to, although an error might arise in observing the hyperæmia in the cutaneous surface, as it is doubtful whether this relationship in the circulation exists in the lower tissues corresponding to the superficial.

Fuchs remarked that this point in the diagnosis was of immense value to the surgeon. He had practised it on a small scale and found the relative closing of the vessels prominently marked, and is of opinion that where there is an intermitting lameness this method will be of great service in the diagnosis.

Iselsberg related the history of a case with gangrena pedis rising from arterio-sclerosis, where he had to perform a small amputation of the toes, and after relieving the Esmarch tourniquet, hyperæmia extended down to the knee, but the lower part of the leg remained perfectly white. Later the gangrene speedily increased upwards, necessitating amputation at the knee-joint. A microscopical examination of the amputated portion showed that the cutaneous vessels were almost closed.

Schnitzler thought that all were agreed on the importance of the diagnostic symptom, but the doubt still existed whether the cutaneous surface or the deeper circulation represented the morbid changes. Another point he would like to be clear about was the central extension of the hyperæmia not then invaded by the gangrene, or was it certain to stop at the margin of the hyperæmia? It often happens that in senile gangrene where lymphangitis is present the hyperæmia is the herald for a speedy destruction by gangrene with a resulting amputation.

SCOTLAND.

PUBLIC HEALTH ASPECTS OF CONSUMPTION.—The session of the Edinburgh Sanitary Society was opened on November 3rd by an address by Dr. R. W. Philip on "The Public Health Aspects of the Prevention of Consumption." He pointed out that although twenty-five years had elapsed since Koch's great discovery, the community at large had not yet derived the practical benefit from it which might have been anticipated. To this result certain natural causes had contributed. In 1881 the world was not prepared for the swift intimation that consumption, whose nature then was regarded as ascertained, had been thoroughly misunderstood, and that in place of depending on a variety of ill-defined causes, it was due to a specific micro-organism. Although the change which had come over the pathological conception of the disease during the last quarter of a century was immense, and had led to great strides on the therapeutic side, much still was called for in regard to the more public aspect of the question, and there was clamant need for a vastly wider organisation and co-ordination of measures than had yet been recognised. The solution of so far-reaching a social problem could only be attained by concerted action throughout the country. Any scheme should include the following factors:—(1) Notification of the disease; (2) a tuberculosis dispensary; (3) a hospital for dying patients; (4) sanatoria for selected cases; and (5) colonies for residence of latent or arrested cases. Compulsory notification afforded the only sound solution of the consumption problem. It was often asked, After notification—what? Notification did not imply that all affected persons were to be removed to a hospital. In some cases, however, it would lead to the discovery of a whole nest of the disease, and then compulsory notification would lead to a vast number of questions as to how the focus of infection should be dealt with.

COMPLIMENTARY DINNER AND PRESENTATION TO DR. T. M. BURN MURDOCH.—Dr. Burn Murdoch, who has lately resigned his position as Senior Physician to the Royal Hospital for Sick Children, after a period of service extending to nearly a quarter of a century, was entertained to dinner on November 10th by his colleagues on the hospital staff, his former residents, and his old assistants. Dr. Melville Dunlop occupied the chair, and in a felicitous speech proposed the guest's health, at the same time asking his acceptance of a piece of plate in token of the feeling of affection and esteem which all those who had been associated with Dr. Burn Murdoch felt towards him.

EDINBURGH ROYAL INFIRMARY.—At last week's meeting of the managers, it was reported that Dr. J. Malcolm Farquharson had been promoted from the post of Assistant Surgeon to that of Junior Full Surgeon to the Ear and Throat Department, with a share of the beds. The following gentlemen were appointed Clinical Tutors for the current winter and ensuing summer sessions, viz.:—Alexander Goodall, M.D., F.R.C.P.Ed., to Dr. Alexander James; W. G. Porter, M.B., B.Sc., F.R.C.S.Ed., to Dr. Logan Turner. Re-

cognition was taken of the retirement of Dr. Allan Jamieson from the post of Physician to the Skin Department of the Infirmary, to express to him their grateful thanks and in token of their esteem and in acknowledgement of his services, they appointed him Consulting Physician.

LETTERS TO THE EDITOR.

THE GENERAL COUNCIL—THE ELECTION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The approaching election of direct representatives invites contemplation. Our discussion shall be calm and philosophical. And on first glancing through the various addresses, no definite issue nor distinct principle appears. Each candidate seems in breathless haste to tell us what he has done, what offices he has held in the various professional societies and associations. Yet we see from this that the decision must turn on the personal qualities of the candidates—not only their beliefs, but their power of expression and their power to persuade indifferent or opposing members of the Council. Herein is an argument for the division of England into electoral provinces, for few men can be very widely known for their administrative qualities.

The next feature is the absence of enthusiasm for reform. Of course, they all say that their number should be increased. That is the proper thing to say. One candidate advocates reform *on the lines* of the Bill proposed by the Association. Only one, I think, goes in for the whole Bill.

The demand for increase in the number of direct representatives, *i.e.*, for increased influence on the Council, goes to the heart of things. It means there is much to be done and none but those who form the great bulk of the profession—the practitioners—can understand either what to do or how to get it done. Consider these cases.

An old man who has toiled all his life as an Irish dispensary doctor receives, at 70, no pension, and is sent into the workhouse. Would this be possible if the Council represented and had truly looked after the interests of the profession?

It is an old story, that of the unqualified assistant. Many were fairly skilful in many ways, steady and hard-working. They were turned off without fault of theirs, without compensation, and so far as the Council cared, left to starve. Let us not forget that, although less competent, they filled in some ways a useful transitional stage, and in a sense were members with us of one calling. Good and bad were treated alike.

What has been the answer of the Legislature? By the Midwives Bill, a class of subordinate practitioners has been again created: women, with no general education, far less qualified than many of the late unqualified assistants. When this Act was passing, the Council were asleep. Their voice was feeble *because* they do not in truth represent the profession. These consultants and lecturers are in us, but not of us.

A man in Aberdeen got drunk. He was struck off the *Register*, and I do not read that any hand was lifted up against it, or that anyone asked that he should have another chance. I know nothing of the fellow: what trials, what disappointments brought him to take an overdose of the anæsthetic. I would like to know though, if the secretary of a Division, or a member of a Branch Council, attended at the police-court to take the man by the hand and attempt his reformation. I wonder, also, when those well-to-do members of the General Medical Council had gone home and were sitting in their warm dining-room over the walnuts and the wine, if they had any thought of their Brother outside in the dark, whom their action had thrust a little deeper into hell. For the man from Aberdeen is not one man. He is a hundred men. We cannot tell how many. One by one they sink beneath the surface and are forgotten. Is it not for those who represent a humane profession to look after the weakly ones? But have I said "wine"? I made a mistake. If it be infamous to get drunk, it is surely infamous to drink. Possibly there are degrees in infamy.

Yet another case. This, a rich man, or at least well-to-do, living in his own house. He was trustee, and mismanaged the trust; he spent the income on his own pleasures. This is nothing to the General Council—not meriting even an inquiry. This man is not as that poor drunkard, who had no friend in the world. This one is well off. So that to rob the orphan is no offence—at least, if you are affluent.

Have I been able to make my meaning clear? It is: that excellent as are strictness in examinations, and a reasonable standard of honourable conduct, *i.e.*, professional etiquette, there is yet waiting to be dealt with an enormous mass of subjects relating to the personal welfare of the rank and file of the profession. We have been waiting patiently for years. As one candidate says: "the legislation of the past twenty years has decreased by one-third the earning powers of the general practitioner." Not legislation alone, but misapplied philanthropic effort. One candidate will "further the interests of those engaged in general practice." Another says "adequate remuneration," "fair payment for our services." This is the right sort, although these words do not go very far, in regard to method at least. But what stuff is this: "raise the standard of preliminary examination"; "a yearly tax on all who practise." We want men who will put, not their brain only, but their heart into the interests of the G.P. Those cases of old-age destitution, etc., we have referred to should be utterly impossible in five years' time, when our candidates return for our suffrages. On this occasion there is no pure consultant candidate. They have all passed through the mill. An immediately important question, it seems to me, is that of the provident dispensaries, many of which sadly want supervision. Only one candidate—perhaps two—puts this forward with definite clearness; others do not allude to it. To sum up, we want to represent us men who understand "the difficulties and trials, as well as shortcomings of everyday practice."

I am, Sir, yours very truly,

GEORGE CRICHTON, M.D.

114, Lexham Gardens, London, W.

WE are asked by the Hon. Secs. of Dr. Broadbent's Committee to insert the following:—

ELECTION OF DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL COUNCIL, 1906.

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

Ladies and Gentlemen,—At the Quarterly meeting of the Medical Guild, Manchester, the following resolution was unanimously carried:—

"That this meeting warmly supports the candidature of Dr. G. H. Broadbent at the forthcoming election to the General Medical Council, and trusts that practitioners will do all in their power to secure his election. This meeting also entirely endorses the sentiments expressed and claims put forward by Dr. Broadbent in his address (MEDICAL PRESS AND CIRCULAR, Oct. 31st), and is confident that the interests of the profession may be well entrusted to his care."

Dr. Broadbent was nominated originally by the North Manchester Division of the British Medical Association, and his Committee appeal for your support on the following, among other grounds:—

1. That he has been engaged in general practice for upwards of 25 years, and his knowledge of medico-political subjects is such as to make him a a desirable representative.

2. That he has had special experience in medical politics as a member of the Central Ethical Committee, a representative at the annual Representative meetings since their inception, a member of the Lancashire and Cheshire Branch Council, Ex-president of the Incorporated Medical Practitioners'

Association, and a member of the Council of the Medical Guild since it began 14 years ago.

3. That he is opposed to Provident Dispensaries and disapproves of the profession undertaking any new contract work, and has always insisted on a wage-limit in all contract work.

On these grounds his Committee confidently appeal to General Practitioners all over England for their support and vote for Dr. Broadbent at the ensuing election. If you can see your way to allow your name to be added to his Committee, will you kindly notify,

Yours faithfully,

J. H. Taylor, M.A., M.B.,
Holly House, Salford.
R. G. McGowan, M.D.,
1, Thomas Street, Manchester.

THE DECLINING BIRTH-RATE.

To the Editor of The Medical Press and Circular.

Sir,—It takes some courage to stand up for an unpopular cause as your correspondent, Dr. Clement Sers. does. There may be evils and abuses in the limitation of families—there are in all good movements—but what does the movement show? Surely, that people are thinking for themselves, as Dr. Sers shows; that they are refusing to add to the twelve million who can barely exist under the present stress of life. Take my own county, for instance. Our able medical officer of health has just presented his annual report, and it tells the same tale that it has told for some years past—fewer births and fewer deaths. The birth-rate has fallen from 25.56 last year to 25.06 this, the birth-rate of England and Wales being 27.2. Against that set our mortality. The death-rate, like the birth-rate, is the lowest on record—namely, 14.32 per 1,000, as compared with 15.2 for England and Wales. In the present condition of things I hold that to be a result one can be proud of. Moreover, the total gain in population by lowering the death-rate is not counterbalanced by the loss through fewer births. Besides, with the lowered birth-rate goes a lower infant mortality rate, showing that *people are becoming more careful of human life*. That, to my mind, is a great gain to civilisation.

I am, Sir, yours truly,

Lancastrian.

Bury, Nov. 9, 1906.

INFANTILE MORTALITY.

To the Editor of The Medical Press and Circular.

Sir,—The experiment which the Mayor of Huddersfield initiated on taking office two years ago has produced the result which might safely have been predicted. No proof, to my mind, was needed of the fact that the excessive infantile mortality which prevails throughout the country is in great part preventable; but the experiment is none the less valuable as showing that the death rate can be reduced at once by one half by private effort, without the new legislation which is constantly demanded for the treatment of the social evils of this and similar kinds which afflict society at the present day. The Mayor's offer of a birthday gift of £1 to every baby born during his period of office, and surviving a year, was not intended as a stimulus to maternal care. The experiment was to see whether by constant watchfulness and help on the part of lady workers the death rate could not be reduced. The average rate during the previous ten years had been 122; whilst during the two years of the experiment it had been lowered, at the highest estimate, to 53. Infantile mortality is, of course, only a rough measure of the injury inflicted upon the populace by the causes to which it is due. For every baby dead there exist among the survivors large numbers with constitutions damaged by the period of malnutrition and illness through which they have passed—the halt, the lame, the blind, and the ricketty and "scrofulous" cripples who swell the army of unemployables and paupers which forms so terrible a burden upon the State. I trust, sir, that the ball set rolling by the Mayor of Huddersfield will have a long journey.—Yours truly,

Brighton. G. P. Londinensis.

OBITUARY.

ROBERT HAMILTON BELL, M.A., M.B., B.C (Cantab.), M.R.C.P., F.R.C.S.

The death of Dr. R. Hamilton Bell, of 27, Seymour Street, London, W., on October 29th, at the age of 35, is one of those tragic episodes that especially excite the sympathy of the members of our profession. That a man of great promise should be cut off at this early age and just as years of hard work and preparation seemed about to bring their well-deserved reward in the shape of an assured position and of professional success is indeed a matter for profound regret. And it may be truthfully said that Dr. Bell fell a victim to his assiduous devotion to his professional duties. Apparently a man of strong constitution, the strain involved in the constant attention he gave to those hospitals that claimed his services and the zeal with which he threw himself into all medical work combined to overtax his strength so that he was unable to fight the terrible acute disease which struck him down. A slight throat affection developed with startling rapidity into a double pneumonia of a low form, and to this he succumbed after a few days' illness.

Robert Hamilton Bell was educated at Trinity College, Cambridge, and at St. Thomas's Hospital, graduating in medicine in 1898. Devoting himself to obstetrics and gynæcology, he had been engaged in consulting practice for some five or six years, and was physician to out-patients at the Great Northern Central Hospital, at the Samaritan Hospital for Women, and at the British Lying-in Hospital. He was also obstetric tutor and Registrar at St. Thomas's Hospital, and examiner to the Central Midwives' Board.

Dr. Bell was a man of wide culture and sympathies, and was most popular with his hospital colleagues and professional brethren, and he has enriched the literature of his especial branch of medicine by several important contributions. Among them were papers on Puerperal Eclampsia, on Thyroid-like Structures in Ovarian Cysts, Torsion of the Pedicle in Hydrosalpinx and other morbid conditions of the Fallopian Tube, &c.

After but three years of married life he leaves a widow and one child to mourn his death, and many friends to grieve over the loss of a bright and charming personality and a trusted professional brother.

DUNCAN ROBERTSON, M.B., C.M.

We announce with sorrow the sudden death of Dr. Duncan Robertson, of Callander, N.B., on October 30th. Dr. Robertson went to his room to rest before going out in the evening, and on being called to see a patient was found dead in bed. Dr. Robertson was an M.B., C.M., of Edinburgh, and a little over forty years of age. He had been in practice in the district for about ten years. The early death of Dr. Robertson, so widely known as a skilful physician, and so universally liked for his genial character, is deeply regretted.

J. HAMILTON CRAWFORD, M.D.Edin., D.P.H.

We regret to record that the promising career of Dr. Crawford, of Bradford, was cut short on October 29th by death after an operation. Educated at Edinburgh, he took his M.B. and C.M. in 1891, and his M.D. with commendation in 1899. After being a demonstrator in pathology at Edinburgh, and a Demonstrator of Anatomy at Minto House School, he became house surgeon at Bradford Royal Infirmary. Settling in the town, he was elected assistant medical officer to that institution, and assistant surgeon to the Eye and Ear Hospital. Dr. Crawford was very popular with his colleagues, and his funeral was largely attended by members of the profession.

SPECIAL ARTICLES.

REPORT ON THE DUBLIN HOSPITALS.

In noticing the Annual Report of the Board of Superintendence of the Dublin Hospitals (*a*) we must, in the first instance, express our regret at the death of the Secretary of the Board, the late Dr. William J. Martin, who has edited the Report for many years, and whose courtesy made his intercourse with the officials of the various hospitals a pleasure to them.

The hospitals subject to the supervision of the Board are those in receipt of grants from Parliament, being nine in number. With their respective grants they are as follows:—Westmorland Lock, £2,600; Dr. Steevens', £1,300; Meath, £684 12s. 8d.; Cork Street, £2,500; House of Industry, £7,557 16s. 8d.; Rotunda, £700; Coombe, £200; Royal Hospital for Incurables, £250; and Royal Victoria Eye and Ear, £100. Only three of the institutions named, viz., Dr. Steevens', the Meath, and the House of Industry, are general hospitals.

The Board express general satisfaction with the management and condition of the hospitals throughout the year, and note that they have had no serious complaints to consider. They also comment on the marked improvement in the Dublin hospitals during the twenty years which have elapsed since Lord Aberdeen's first viceroyalty, and on the fact that the Dublin School has borne its full share in the advance of scientific medicine.

On April 1st, 1906, there were 957 patients in the hospitals under the supervision of the Board. The number admitted during the year was 11,601, making the whole number under treatment 12,226, of whom 11,052 left the wards either cured or relieved, or were discharged for other causes, and 469 died. 1,037 patients remained under treatment in these hospitals on March 31st, 1906. Exclusive of incurables, the mortality was 3.74 per cent. on those treated to a termination. The total daily average number of beds occupied in these hospitals throughout the year was 940.02. The time spent in hospital by each patient under treatment (omitting the patients in the Royal Hospial for Incurables) averaged 23.74 days.

In the three general hospitals inspected, the mortality on cases treated to a termination, the average number of beds occupied, and the average stay in hospital, were 4.14 per cent., 102.2 beds, and 24.69 days in Dr. Steevens'; 7.04 per cent., 103.45 beds, and 27.56 days in the Meath; and 6.83 per cent., 145.48 beds, and 26.75 days in the House of Industry.

The list of diseases treated in the various hospitals does not present many features of special interest. We note that typhoid fever is still prevalent in Dublin, 284 cases having been treated during the year, with a mortality of 31, or 10.9 per cent.; 11 cases of typhus were treated, without any death; there was no case of small-pox; there were 6 cases of tetanus, with 4 deaths.

The tables exhibiting the items of expenditure in the various hospitals present some remarkable contrasts. Thus, the average annual cost per bed for maintenance varies from £13 0s. 10d. in the Royal Hospital for Incurables, and £13 3s. 3½d. in the Lock Hospital, to £23 6s. 9¾d. in the Meath, and £24 12s. 4d. in Dr. Steevens'. Again, it is not easy to see why the expenditure on stimulants in the Coombe Lying-in Hospital, with an average of 32.3 beds occupied, should be £10 3s. 8d., while that in the Rotunda, with an average of 82.09 beds occupied, should be little more than half that sum—£5 14s.

The total expenditure on the nine hospitals under the Board amounted to £57,520 5s. 1d.

SLUMDOM IN LIVERPOOL.

We have received a reprint from a series of articles on this subject by the special commissioner of the *Liverpool Courier*.

The articles form interesting reading, and might, if properly brought out, have a practical outcome in good.

First of all comes the name Slum Trouble. The word "slum" is one savouring very strongly of Phariseeism, with a capital P., and probably no one but a Pharisee would ever think of making use of it. But we let that pass, as we know what it means, or what it means in the minds of those who make use of it. The writer states: "I must candidly admit that I commenced my investigations with a feeling that drink was the chief cause of the poverty. Perhaps it was only natural that I should incline to that view, because I am a lifelong teetotaller. . . . Be that as it may, my tour in the slums, prolonged on more than one occasion until after the public-houses were closed, has resulted in revelations which have certainly surprised me."

Although the commissioner does not profess to have solved the question of destitution and squalor that certainly exist, he has come to certain conclusions, as, for instance: "The overwhelming evidence of my investigations convinced me that misfortune—lack of work, casual labour, etc.—was the chief cause of poverty; and that utterly inadequate domestic arrangements constitute the principal reason for squalor." Lack of work is undoubtedly a main cause of the destitution. It may not be known everywhere that for dock work, in the loading and unloading of ships, the pay is good. This brings people to the city, and the docks are plentifully supplied with labour. But on the other hand, the work is very irregular, and often men will be unable to get more than one or two days' work a week. Good wages are therefore a snare in this case. They attract labourers who are doomed to disappointment, as they cannot get the work the pay for which tempted them. Two days' work a week at 4s. 6d. a day do not go far to support a family. So much for lack of work.

Inadequate domestic arrangements the Commissioner puts down as accounting for the squalor. This is in the main true, but it is not all the truth: the Irish Invasion, of which he speaks, accounts for a good deal of it. These people, we are told, came over to Liverpool in vast multitudes in 1847, the year of the potato famine. "By the end of June of that year more than 300,000 of these destitute peasants had arrived," and "it is calculated that 80,000 located themselves in Liverpool." We would like to quote further, but space forbids. The residue left stranded in Liverpool were naturally the most wretched and the least educated and intelligent. They were just as naturally those who were too helpless to move on. One may imagine the effect of the dumping of thousands of destitute people, who must live by work or other less honourable means, in a circumscribed area where work was not too plentiful before. It would simply swamp native labour. Besides this, the ignorance and squalor of these poor people acted as a blight that has not yet entirely passed away. Drink certainly plays a part, but the degrading ignorance of these classes contributes to it, as when a man's home is noisome and disgusting he will perforce seek solace elsewhere. But the subject is too big to pursue here, and we can only ask ourselves what is the remedy? The answer is not coddling, but education of the young, on whom alone rest our hopes.

REVIEWS OF BOOKS.

LABORATORY MANUAL OF PHYSIOLOGY. (*a*)

The increasing value attached to experimental work in biological science is one of the outstanding features of medical education at the present time. This particularly applies to the subject of practical physiology, which, as taught nowadays to the medical

(*a*) Forty-eighth Annual Report of the Board of Superintendence of the Dublin Hospitals, with Appendices, for the year 1905-1906. Dublin: H. M. Stationery Office. 1906.

(*a*) "Laboratory Manual of Physiology." By W. C. Busch, B.S., M.D. New York: Wm. Wood and Co. London: Bailliere, Tindall and Cox. Pp. lx., and 206. Illustrations, 47. Demy 8vo. Price 6s. net.

student, is becoming more and more the handmaiden of clinical medicine and clinical therapeutics. Nor can this tendency be considered as anything but beneficial both to medicine and physiology. To the former it brings disciples better prepared to apply the methods of scientific investigation to clinical work. To the latter it brings sympathy and incentive to work along particular lines, both of which are of great value to investigators in the subject.

In the preface to the work before us, which is described as "an outline of experimental physiology in brief and concise form," the author makes a claim which will be conceded by all, namely, that one of the main benefits to be obtained from laboratory work is the training in methods of exact observation.

Dr. Busch's book begins with an introductory study of one or two representatives each of the algæ, the fungi, and the protozoa. These are taken as types wherewith to illustrate the fundamental activities of animal and vegetable protoplasm. Amongst the flagellate infusorians is mentioned a trypanosoma found in frog's blood.

The following sections are then taken up in order :—(1) Muscle nerve physiology ; (2) nervous system ; (3) blood ; (4) circulation ; (5) secretion ; (6) digestion, absorption ; (7) respiration ; (8) excretion ; (9) sensation ; (10) vision.

The space allotted to each section shows that the balance is very evenly held between the different subjects. If the book be divided into twenty units of ten pages each, broadly speaking, four of these units go to experiments on the circulation, three units to muscle nerve physiology, two units to each of the sections on blood, secretion, respiration, and vision, while one unit is given to each of the remaining five sections, including the introduction.

The treatment of the individual subjects is also to be commended. All through, even in the chapters on muscle nerve physiology, experiments practically useful are selected in preference to those less applicable to everyday requirements, and this without sacrifice of educational value from the purely scientific standpoint. This is exemplified in the section mentioned, by the choice of experiments on the fatigue of human muscle, the stimulation of human nerves, the influence of load on the work of the muscle, the reaction of degeneration. As regards the latter, the experiment related, extremely instructive though it be, could not be performed in this country, even by a teacher of physiology, without the necessary legal permission. The book, however, is primarily written for the American worker.

The instructions for the performance of the experiments are certainly concise, but they border on scantiness ; evidently the author contemplated no lack of skilled assistants to aid the junior investigator.

From the standpoint of the British teacher of physiology, the work presents certain other striking features. The range of practical instruction in the branches of physiology of which the book treats is much beyond what could be demanded from or attempted by the medical student in this country under present conditions. But it must be at the same time admitted that there is hardly a superfluous exercise in the whole book, and that British students would gain immensely by having practised all of them. This programme, however, could not be carried out in Great Britain by any except holders of licences and certificates under the Act 39 and 40 Vict. c. 77. A large proportion of the experiments in all of the sections, and many of these the most instructive, are not otherwise permissible in this country. More is the pity ; for the student who systematically performs experiments on the anæsthetised frog, pigeon or rabbit, who puts into practice and studies the effect of removal of the pancreas or the thyroid from the dog, who investigates the effects of excitation and removal of parts of the cortex of the brain of the mammal, gets an insight into the functions of organs, otherwise unattainable, and at the same time learns operative technique in a way that can only be acquired by practice on the living being. The learner, however, in this country must count himself happy if he has had the opportunity of witnessing demonstrations of many of the most fundamental experiments here detailed which his American *confrère* can personally perform. Indeed, it must be confessed that few of the laboratories in this country are at present sufficiently equipped to enable any but a limited number of students to carry out the range of experiments here detailed.

Dr. Busch's book does not profess to cover the ground of physiological chemistry. This part of the subject has by many come to be regarded as a special one in itself. It has, however, to be borne in mind that physiology, and, indeed, biology generally, are becoming more and more chemical every day, and while one cannot restrict the ideal, teachers have to keep this point in view when planning courses of practical instruction for students whose time for a given subject is limited.

To sum up, the book is undoubtedly an admirable one, and British teachers will find in it a range of most useful and suggestive experiments from which to select, both for class work and lecture demonstrations. Many of them will also envy the superior opportunities of both teacher and student, who are provided with time and means for going systematically through the whole of this work.

THE KING'S CORONER.(*a*)

In Volume I., Mr. Henslowe Wellington devotes the first thirty-four pages to an historical outline of the office of coroner. As regards the origin of the office he suggests that it is at least as old as King Athelstan, since the word "coroner" occurs in the Charter of Privileges granted to St. John of Beverley in A.D. 925. It is, however, considered by the highest authorities on Saxon that the word "coroner" was inserted in the charter by a copyist at a period some two hundred and fifty years later.

The origin of the office certainly dates as far back as the Articles of Eyre, in A.D. 1194 (Richard I.), and there is evidence of its existence during the earlier reign of Henry II. The first printed edition of a statute containing the word "coroner"—as pointed out by Mr. Wellington—occurs in the Great Charter, A.D. 1225. We agree with the author that the statement made by some writers to the effect that the offices of mayor, chamberlain and coroner in the City of London were held by the same person is not tenable. Neither is it true that the Lord Mayor ever was, or is, *ex officio* coroner. Prior to A.D. 1478 the offices of king's butler, king's chamberlain, and coroner were held by one and the same individual. Mr. Wellington, following other writers, confounds the "king's" chamberlain with the City chamberlain—two entirely distinct officials.

The remainder of Volume I. is made up of a complete collection of the statutes relating to the office of coroner. This part of the work makes somewhat dry reading, but is, however, of historical interest as showing the gradual evolution of the office. The Coroner's Act, 1887, under which coroners of the present day carry out their duties, is supplemented by many useful footnotes. The frontispiece to Volume I. gives an artistic representation of the seal of the coroner of the king's household during the fourteenth century.

Volume II. contains chapters upon the practice and procedure before an inquest is held, upon the proceedings in court, and after the court has risen, with the necessary forms in swearing witnesses and in issuing orders, warrants, and other official documents. The opening chapter contains valuable matter, including a brief outline of the local constitution of the country in early times complementary to the historical sketch given in Volume I.

(*a*) "The King's Coroner: being the Practice and Procedure in his Judicial and Ministerial Capacities." By R. Henslowe Wellington, of the Middle Temple, Barrister-at-Law, Deputy Coroner for the City and Liberty of Westminster, &c., Lecturer on Medical Jurisprudence at the Westminster Hospital Medical School, M.R.C.S.Eng., L.R.C.P.Lond. In two vols. London: Bailliere, Tindall and Cox. Vol. I., pp. 292, 8s. 6d. Vol. II., pp. xvi-148, 7s. 6d. 1906.

The index in each volume is exhaustive, but the value of the work would, we think, be much enhanced by the provision at the beginning of each volume of a full table of contents, together with a table of cases cited. Mr. Wellington, under Part I., rightly enters somewhat fully into the important subject of "Procedure before the Inquest." This part of the coroner's work often gives him more responsibility than the actual holding of inquests, and is increased by recent Acts of Parliament, such as the Employer's Liability, Workmen's Compensation, Factory and Workshops, Infant Life Protection, Lunacy, Prisons, Fire, and other statutes.

Under Part II., which treats of the court and the procedure therein, the author says he knows of no definition of what constitutes "a body," so that the coroner must use his own discretion in holding an inquest on a portion of a body or on a mummy or in the case of still-birth. Mr. Wellington is silent as to the advisability or otherwise of the retention of the view of the body.

Mr. Wellington makes the unsupported statement that "It is not always necessary to have medical evidence at an inquest, so that the expense of calling it should not be incurred unless the coroner is satisfied that a skilled and scientific examination is necessary in order to determine the cause of death, or that it is necessary for the jury to have a history of the deceased's illness and treatment. We presume, however, by this he refers to those comparatively rare cases only in which the cause of death is self-evident—*e.g.*, in those seen deliberately to cast themselves into a river and be drowned, or seen to throw themselves from a height, or killed outright by means of a railway accident. But even in some of these cases medical evidence is advisable.

In Part III. mention is made of the unique power possessed by the coroner of the City of London to hold inquests in cases of City fires without loss of life. We think some expression of opinion might with advantage have been added with regard to the extension of like powers throughout London and to the large towns—at least, in England and Wales.

In the next edition a chapter might, with much practical advantage, be added on the subject of homicide. In such a chapter the legal definition and differentiation between the crimes of murder, manslaughter, and suicide might usefully be given, together with some account of other kinds of killing by neglect, accident or otherwise.

Altogether Mr. Wellington is to be congratulated on the results of his painstaking labours, and we would certainly recommend all those interested in coroner's work to avail themselves forthwith of the valuable summary of coroner's law contained in Volumes I. and II. of "The King's Coroner."

"CLINICAL DIAGNOSIS." (*a*)

So many excellent books on clinical diagnosis have recently been published that there seems little room for another, and this fact is admitted in the preface to the volume before us. The distinctive feature of the present work is that it considers clinical laboratory work from the clinical rather than from the laboratory point of view. The work is based on experience obtained during seventeen years of work carried out in the United States at the famous Johns Hopkins Hospital and University. Thus we find on going through the pages of this book that every fact stated is supported by clinical or other practical evidence. There are in all six chapters, covering some six hundred pages altogether. The first chapter treats of the sputum. Its appearance in various diseases is carefully indicated, the description of the sputum met with in asthma being one of the best we have yet seen. A beautiful coloured plate of the sputum got in cases of influenza has been inserted and has been admirably reproduced. One would imagine that the chapter on the urine could hardly contain anything new or striking, but this is far from being the case. The account given by the author of urinary pigments is specially complete and accurate. It is pointed out that the indoxyl-sulphate of the urine seems to bear some relation to the output of albumen, while it may indeed be of importance in relation to the early diagnosis of nephritis. The author finds it very valuable. When the reaction is present it is strong evidence in favour of typhoid fever. Glycosuria and acetonuria are given more than the usual prominence, and many less well-known but nevertheless important facts are introduced here for the first time into a text-book. Nearly thirty pages are given up to the consideration of albuminuria, and nothing of practical importance seems to have been omitted by the author.

In the third chapter—that dealing with the examination of the gastric contents—we find all that is best in American teaching on this subject referred to. In speaking of ulcer of the stomach Emerson incidentally refers to a clinical variety which he names the "vanitive" form. We do not like this word, even when it occurs in an American text-book. He sums up well the present position regarding the diagnosis of gastric cancer by laboratory methods when he says, "The chemical features may be very suggestive, in some cases normal, in some even the reverse of those suggesting cancer. At present we admit that age and clinical history are of far more importance than chemical examination." The chapter which treats of the intestinal contents and the fæces is short, but sufficient. Turning to that on the blood we are face to face with quite an array of interesting facts, many of which are extremely suggestive from the diagnostic and therapeutic points of view. The various methods of blood examination are explained in great detail, and the question of the diagnostic importance of leucocytosis in disease is very fully entered into, a list of conditions in which it occurs being given. The concluding chapter treats of the examination of various body fluids such as serum, cerebrospinal fluid, as well as the synovial and amniotic fluids. After a careful perusal of this work we consider it to be one of the best yet written on the subjects; it is well adapted to the needs of senior students and general practitioners who wish to keep themselves informed of modern advances in laboratory methods. It is also well printed and illustrated, and is supplied with a very copious index. No one who studies its pages can fail to derive fresh information and fresh ideas for clinical research.

By Charles Phillips Emerson, A.B., M.D., Resident Physician, The Johns Hopkins Hospital, Associate in Medicine, The Johns Hopkins University. Philadelphia and London: J. B. Lippincott Company. Price, 21s. net.

MOVABLE KIDNEY. (*a*)

THIS is one of the "Actualités Médicales" Series, published by Bailliere. In this small monograph, the author, who is well-known in the department of renal surgery, gives a clear account of the cause, symptoms, and treatment of movable kidney. He holds the view that movable kidney is merely the local manifestation of a general disease, a disease which shows itself in the nervous, the muscular, and the fibrous tissues of the body, the nutrition of all of these tissues being disturbed; in the majority of cases the mobility of the kidney is the first marked symptom. Numerous complications of movable kidney are discussed, clearly and with one exception briefly, for hydronephrosis caused by kinking of the ureter, when the kidney becomes displaced, is treated at considerable length, and deservedly so, since it is the most common, as well as one of the most serious troubles which occur in connection with this complaint. The author shows how difficult it may be to diagnose intermittent hydronephrosis. The condition when present nearly always requires operative treatment, and only in those cases in which the pelvis of the kidney is not greatly

(*a*) "Le Rein Mobile." (Movable Kidney). By Felix Legueu.

dilated is the condition likely to be relieved by merely fixing the kidney; where the pelvis of the kidney is dilated and deformed a uretero-pyelonostomy is alone likely to relieve the patient's symptoms. In most uncomplicated cases of movable kidney, the use of a suitable belt is sufficient, and only when this fails to relieve the pain, dyspepsia, and neurasthenia, is fixing the kidney advocated, Guyon's operation being the method advised. A full and clear description of the operation is included in this excellent contribution to renal surgery.

TOXINES AND ANTITOXINES. (*a*)

THE time had undoubtedly arrived when it became necessary to gather together into a single volume all the scattered and miscellaneous facts that have been discovered in connection with bacterial and other toxines and their antitoxines, and in making such a compilation Dr. Oppenheimer places the medical profession generally and all who are interested in the subject under a heavy obligation. The work can have been by no means of an easy nature, as in almost every case the original papers had to be consulted, and the number of these can be judged by a reference to the bibliography at the end of the volume. Indeed, if his labours had been confined to the mere collection of this reference list, no small service would have been rendered, as it is often difficult to discover the whereabouts of the original articles bearing on the less well-known toxines. The present translation now makes the book more accessible to the English reader, and as it has been brought thoroughly up to date, is even more useful than the German edition. In dealing with such a technical subject one would expect some stiltedness in the style of a translation; but this is not the case, for the whole book is most readable, and its diction excellent. The volume is divided into a general and a special part. The first deals with the general characters of toxines, including the methods of preparing them, and their general relation to antitoxines is discussed. In adopting a definition for the word "toxine," and a limitation to the subject of the book, Oppenheimer follows Erhlich, and excludes from the toxines "any poisonous substance that is not a haptine, and that does not produce an antitoxine." This limitation is very convenient, and has to be carefully borne in mind in order to understand and follow the terminology of the book. After dealing with the toxines, an excellent account of antitoxines, toxoids, and toxones concludes Part I. The second and special part of the work is divided into four sub-sections, dealing respectively with (1) the true toxines, of which the products of the diphtheria and tetanus bacilli are the most important, and in consequence receive the most space; (2) the endo-toxines; (3) the vegetable toxines; and (4) the animal toxines. Most of the sections and articles seem to be very complete, though one would have expected that a little more detailed information would have been given concerning the tubercular endotoxines. The account also of the typhoid poisons is not very complete, but having regard to the general scheme of the work, it is sufficient. On the whole, we regard the publication as a most important one, and think that it will soon be found indispensable in every bacteriological laboratory.

MARTINDALE'S EXTRA-PHARMACOPŒIA. (*b*)

OUR old friend the "Extra-Pharmacopœia," in this its 12th edition, manifests the disquieting tendency to obesity which one associates with advancing years. In truth, it is the only evidence of senility we can detect. In spite of the addition of some 250 pages, bringing the total up to 1,050, our friend remains "a dapper little gentleman," weighing only a few ounces, smartly attired and as prim as ever. The task of revision, in the hands of Dr. W. Harrison Martindale and Dr. Wynn Westcott, must be a task of ever-increasing scope, because, of course, the more text there is, the more is there to revise. The amount of valuable information between the covers of this small volume has always been of the nature of a surprise, and "the more we gaze the more the wonder grows." Apart from the numerous additions to, and modifications of, the pharmaceutical details and therapeutical applications of standard preparations and drugs, the authors have had to stem the tide of recent introductions, verifying their chemical status and pharmacology while so doing. The "supplementary list of drugs" occupies thirty pages of close print, and the chapter on anti-toxins and organo-therapeutic agents another fifty. The analytical memoranda have been extended to sixty pages, and so on; in fact, every department of practical medicine has been worked up to a high pitch of perfection. The index alone—a valuable feature of the book, is allotted upwards of a hundred pages. The outcome of it all is that Martindale's "Extra-Pharmacopœia" is more than ever before an indispensable *vade mecum* to the physician and practitioner, and we should pity the dispensing chemist who failed to place it in a foremost place among his works of reference.

BELFAST.

THE RECENT TYPHOID OUTBREAK.—The history of the recent outbreak of typhoid in one of the best residential districts of the city is now pretty complete, and makes most interesting reading, illustrating as it does the necessity for vigorous action on the part of the authorities at the earliest possible moment. The first case occurred on August 4th, or, rather, was reported on that date. For some reason suspicion at once attached to the milk supply, and the farm and dairy from which it came were inspected on August 7th, with negative results. Two more cases were reported on the 8th, one on the 10th, and two on the 14th, all among customers of this dairy. Inquiries were made as to sickness on the farm, with negative results. A sample of the milk was sent to Professor Symmers to test, again with negative results. Five more cases were reported in the next fortnight, and meantime the farm was again visited and the water supply examined. During September 14 cases were reported among the customers of the dairy, and various visits and inspections were made, but as no positive contamination was found, the sale of the milk still proceeded. On October 2nd and the dairyman, accompanied by his solicitor, attended at a meeting of the Public Health Committee and undertook to attend to the sanitation of the dairy very particularly, but refused to stop the milk supply to the city, as there was no evidence of its contamination. On October 6th it was reported that a positive Widal reaction had been obtained in the blood of a woman working in the dairy, and that no doubt she had lately suffered from typhoid. In consequence of reports appearing in the daily papers, the dairyman stopped the sale of milk about October 8th, but states, through his solicitor, that he does not admit that there was anything wrong with it. The whole history of the outbreak is instructive, and illustrates the limitations of the public health authorities. Here were about 30 cases of typhoid occurring in an otherwise healthy district, all among the customers of one particular dairy, and yet, for want of direct evidence that the milk was contaminated, its sale went on for about two months after attention was first directed to it. If the law allows no further powers to the local authorities than were exercised in this case, it is clear that it needs amendment.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

AT a meeting of the Council on Thursday last, Mr. Henry Morris, F.R.C.S. (President), in the chair, a letter was read from the Royal Commission on Vivisection, inquiring whether the College was desirous of nominating a representative to give evidence before them. The Council thereupon appointed the President of the College to give evidence. A fresh diploma of membership was granted to Dr. Winslow Anderson, whose diploma was destroyed by fire at San Francisco during the general conflagration in that city. The President reported that the Bradshaw Lecture would be delivered by Mr. Edmund Owen, F.R.C.S., on Wednesday, December 12th, at five o'clock, and that the subject of the lecture would be "Cancer: Its Treatment by Modern Methods." Professor Howard Marsh was elected the representative of the College on the Court of Governors of the University of Sheffield.

The Secretary reported that the following resolutions would be moved at the annual meeting of fellows and members, to be held at the College on Thursday next, the 15th inst.:—

To be moved by Mr. Joseph Smith:

That this twenty-second annual meeting of fellows and members again re-affirms the desirability of admitting members to direct representation on the Council, which as now constituted does not represent the whole corporation.

To be moved by Dr. W. G. Dickinson:

That this meeting recommends that, when the question of admitting women to the College examinations is brought before the fellows and members, this should be done either by means of a corporate meeting or by poll of the fellows and members, inasmuch as the meetings as hitherto held under the regulations of the Council have no authority to determine any question whatever, and their resolutions on other subjects are almost invariably disregarded by the Council.

To be moved by Dr. A. S. Morton:

That in pursuance of their resolution in July last, the Council is hereby requested to make further representations to the Government urging the necessity of amending the Midwives Act next session, in order that provision may be made to secure just remuneration for professional services rendered by medical men under that Act.

To be moved by Mr. George Brown:

That, in view of the overcrowding and straitened circumstances which exist in the profession, this meeting strongly urges the Council to use all its influence to secure the raising of the standard of the preliminary examinations in general education and in science; and this meeting is further of opinion that the time has arrived when chemistry, physics, and biology should be treated as matters of preliminary education, and an examination passed in them before the commencement of medical studies.

The Malthusian League.

AT a largely attended conversazione held at the Finsbury Institute on Thursday last, Dr. C. R. Drysdale delivered an address on the rise and progress of the movement in this country and abroad. He rejoiced that the birth rate in Great Britain had been steadily declining for many years, and that the middle classes were now practically Neo-Malthusians as a body. This, he remarked, is continually being deplored by our Empire-makers; but they do not seem to be aware or the fact that in the same time the death rate has almost steadily declined from 21.6 to 16.2 per 1,000, which should be some compensation. He was convinced that this fall in the death rate is almost entirely due to the reduction in the birth rate, and this view is supported by any comparison which may be made between different countries and different localities. We still increase at the rate of half-a-million yearly, or 1,300 a day, and most of our own legislators have at one time or another admitted the gravity of the question. He considered that the time had now come for the movement to enter on a new stage, and to ask for recognition and discussion in Parliament.

Striking Reduction of Infantile Mortality.

LAST week, in quitting office as Mayor of Huddersfield, Alderman B. Broadbent referred to the result of the experiment which he began at the beginning of his term of office, and which was now complete. The first baby to whom he promised the birthday gift of 20s. was born on November 10th, 1904, and the last on November 8th, 1905, which received its birthday present on that day. During the last ten years the average infantile death rate was 139, and in Longwood (the district where the experiment was tried) for the same period the figures were 122, and the experiment was to see whether, by constant watchfulness and help on the part of lady workers, the rate could not be reduced. His promise of a birthday gift was not intended as a stimulus to maternal affection or care. He had staked £100, and had gained the end at which he aimed. Throughout the two years the conditions had been by no means favourable, as whooping cough and measles had been very prevalent, and 1906 was one of the deadliest years on record; 112 babies were born, and of those 107 had actually received the gift he offered. Four of the 112 had died, and one had left the district and could not be traced. Counting only four as dead, the mortality figure was 35, but counting five it was 44, or counting six, due to the overlapping of the periods, the figure would be 53; so that the infantile death rate for the experiment was reduced substantially to less than one-half the average rate, and put into percentages the result would be 54, 61, or 69. The reduction, therefore, was not only appreciable, but it was striking.

Army Medical Reserve of Officers.

A ROYAL warrant included in this month's Army orders amends the constitution of the Army Medical Rerserve of Officers, and substitutes new provisions for the pay, appointment, and promotion of officers.

Under these commissions as lieutenants in the Army Medical Reserve may be given to persons, not over thirty years of age, who may be duly qualified under regulations approved by the Army Council. The ranks of officers of the Army Medical Reserve shall be those of captain and lieutenant, and the total period of service in the Reserve shall be limited to seven years. On the completion of three and a half years' service a lieutenant shall be eligible for promotion to the rank of captain, if recommended for that rank.

Appointments to commissions will be made on probation, and persons so appointed will undergo an initial training of two months, on the expiration of which, should their work and conduct be considered satisfactory, their commissions will be confirmed.

When called to Army service, or while undergoing training, officers of the Reserve shall receive the pay and allowances of officers of similar rank in the Royal Army Medical Corps. After the first year's service an officer shall, in addition to any such pay and allowances for days of actual service, receive pay at the rate of £20 a year. This rate shall be increased to £25 a year if the officer is promoted to the rank of captain.

Officers of the Army Medical Reserve constituted by this warrant shall be liable to be called to Army

service at home or abroad at a time of emergency, and shall also be subject to the general regulations applicable to Army Reserve officers. The sum of £5 will be allowed towards the provision of uniform.

Sent to Goal.

Dr. Edward John Havens, a retired medical practitioner, who has resided at Clacton-on-Sea for some years, was charged at Thorpe Petty Sessions, on the 5th inst., with wilfully obstructing a lad on a bicycle on the Electric Parade, and also with damaging a chair on the promenade belonging to the Clacton Urban District Council. It was stated that as the lad was riding past him defendant put out his foot, causing the boy to fall from his machine. With regard to the damage—which was done some days later—defendant mounted a heap of chairs and threw some over the cliff. Defendant had been before the Court several times previously for extraordinary conduct, the last time for firing a loaded revolver in the street on a dark night. For damaging the chairs he was fined £4, and for obstructing the cyclist he was sent to prison for seven days, without the option of a fine.

Death from Lock-Jaw in Newcastle.

Touching the death of Mr. David Key, of Blyth, who died recently at the Royal Victoria Infirmary, Newcastle, an inquest has since been held. Thomas Blackett, of Blyth, said that the deceased, while walking down his garden-path on October 25th, stepped unawares on to a nail in a plank which was lying across the pathway. The nail penetrated the sole of his left foot, and was with difficulty withdrawn. Mr. Keys was medically treated, but the condition of his foot became so serious as to necessitate his removal to the Infirmary. Dr. Cunningham, house surgeon at the institution, said that when Mr. Keys was admitted to the Infirmary tetanus had already set in. Gradually it developed and caused his death. The small wound in his foot showed signs of having been caused by a rusty nail. A verdict in accordance with the medical testimony was returned.

Dinner of the Irish Medical Schools' and Graduates' Association.

The autumn dinner of the Irish Medical Schools' and Graduates' Association will take place at the Hotel Great Central, Marylebone Road, N.W., on Wednesday, November 28th, at 7.30 p.m. The guest of the Association will be Admiral of the Fleet Sir Edward Seymour, G.C.B., O.M. Tickets can be obtained by members of the Association from Mr. Canny Ryall, F.R.C.S.I., 85, Harley Street, London, W.

Death under Chloroform at Liverpool.

The Liverpool City coroner held an inquest, on November 1st, on the body of Martin M'Nulty, æt. 31, a boiler-scaler. M'Nulty had received injuries in the course of his employment some months ago, and had to undergo an operation. On Wednesday it was found necessary to operate upon him for rupture. Chloroform was administered, but before he had had enough of the anæsthetic for the operation to be performed, his breathing became embarrassed, and despite every possible effort he died in about twenty minutes. The jury found that death was due to syncope, and that the chloroform was skilfully and properly administered.

Vital Statistics.

The deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 15.4 per 1,000 of their aggregate population, which is estimated at 17,740,164 persons in the middle of this year. In the preceding three weeks the rates had been 15.5, 14.6, and 14.6. Measured by last week's mortality, the highest annual death-rates per 1,000 living were:—from all causes, 23.7 in Dublin, 20.0 in Birkenhead, 20.1 in South Shields, 20.2 in Preston, 20.3 in Warrington and in Sunderland, 20.8 in Liverpool, 21.9 in Middlesbrough, 22.0 in Hanley, 23.7 in Oldham, and 19.2 in Glasgow; from measles, 2.2 in Oldham, 3.0 in Rochdale, 3.2 in Bootle, 3.3 in South Shields, 3.8 in Warrington, 4.3 in Rotherham, and 4.9 in Norwich; from scarlet fever, 1.6 in Wolverhampton; from diphtheria, 1.3 in Aston Manor and 1.5 in Ipswich; from whooping-cough, 1.6 in Middlesbrough; from "fever," 1.5 in Warrington; and from diarrhœa, 2.6 in Rotherham, Middlesbrough; 3.3 in Oldham, and 4.9 in Preston. No death from smallpox was registered in any of the eighty towns.

Death under Chloroform at Halifax.

Mr. E. W. Norris held an inquest at Halifax, last week, on John Wood, 55 years of age, who died under chloroform at the Nurses' Home on Sunday. Evidence having been given to show that the chloroform had been properly administered, the jury returned a verdict of "Death from misadventure."

PASS LIST.

Royal College of Surgeons, England.

The following candidates, having passed the required examinations and conformed to the by-laws, were admitted members of the College on Thursday last:—E. H. Adams, E. Alban, E. Balthasas, A. L. Baly, G. B. Bartlett, H. G. Bennett, A. W. Berry, M. Birks, P. Black, H. O. Blandford, L. H. Bowkett, J. E. M. Boyd, G. G. Butler, W. E. Carswell, C. Cassidy, J. B. Close, A. G. Cole, H. G. Cole, I. R. Cook, J. Couper, S. Barrett, P. P. Daser, H. R. Davies, G. H. Dive, F. C. Doble, L. Doudney, S. F. Dudley, A. G. Dunn, L. Edwards, R. R. Elworthy, D. Embleton, C. H. J. Fagan, J. S. Farnfield, C. H. Fernis, P. Fiaschi, R. D. Forbes, W. Gabe, R. F. Gerrard, S. W. Grimwade, J. R. Gunne, E. H. R. Harries, T. S. Harrison, T. S. Hele, D. W. Hume, R. W. Ironside, T. J. Jenkins, D. M. Keith, T. Ll. Kenion, W. R. Kilgour, W. H. King, C. Lebon, W. H. Lee, R. D. Low, J. A. McCullum, O. R. McEwen, P. D. F. Magowan, E. S. Marshall, J. D. Marshall, D. Manekji Masina, E. W. Matthews, H. B. Maxwell, C. A. L. Mayer, F. E. W. Meadows, O. Le F. Milburn, S. W. Milner, H. V. Mitchell, W. S. Mitchell, E. Morgan, R. J. Mould, L. D. Neave, F. M. Neild, R. B. Nicholson, H. J. Nightingale, T. Norman, H. W. Ogle-Skan, M. W. B. Oliver, G. G. Packe, G. S. Parkinson, E. H. A. Pask, G. D. Perry, G. R. Phillips, A. J. S. Pinchin, A. M. Pollard, E. S. Prior, A. E. Pryse, R. M. Rendall, A. T. Rivers, P. M. Roberts, R. C. Roberts, I. J. Roche, T. R. St. Johnston, C. N. Slaney, H. A. Smith, F. M. W. South, H. McL. Staley, P. K. Steele, A. C. H. Suhr, D. W. Tacey, O. Teichmann, H. E. H. Tracy, F. C. Trapnell, W. H. Trethowan, C. Tylor, I. Valerio, J. P. Walker, S. L. Walker, C. G. Welch, C. E. Whitehead, R. H. Williams, W. S. Williamson, H. D. H. Willis-Bund, J. G. Willmore, J. L. Wood, E. M. Woodman, H. N. Wright, A. B. Zorab, C. E. Zundel.

Trinity College, Dublin.

At the Michaelmas Term, 1906, the following candidates passed the intermediate Medical Examination, Part I.:—R. T. Brooks, J. P. S. Dunn, G. E. Craig, R. D. FitzGerald, W. H. Hart, J. E. M'Causland, W. R. Allen, J. Alston.

Preliminary Scientific Examination.—The following passed in *Physics and Chemistry*:—Dorothea M. Franks, F. J. A. Keane, S. R. Richardson, C. D. Hanan, M. S. Moore, T. G. Hardman, P. F. Nunan, J. W. Flood, V. W. T. M'Gusty, John G. Dods, Hans. Fleming C. J. Pentland, F. Crosbie, E. F. Lawson (Sch.), and E. Garland.

Botany and Zoology.—Mary G. Caskey, M. S. Moore, T. G. Hardman, W. O. Halpin, J. B. Burgess, F. R. Dougan, R. G. M'Entire, L. F. Macan, H. E. Williams, F. Casement, H. L. Blackley, G. F. C. Healy, H. G. G. Holdbrook, T. F. Preen, S. A. Lane, S. A. Dudley, and R. T. Vaughan.

Final Medical Examination, Part I.—J. B. Jones, J. G. M. Moloney and T. Ryan (equal), J. R. Yourell, F. Seymour, H. P. Hart and E. Jameson (equal), T. P. S. Eaves, J. D. K. Roche, W. Knapp, J. P. R. Poch, T. P. Dowley and G. A. Jackson (equal), B. A. H. Solomons.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL SUMMARY.

The Operative Treatment of Acute Gonorrhœal Epididymitis.—In recommending the operative procedure, Haynes (*Medical Record*, October 13th, 1906) draws attention to the pathological reports of Monod and Terrillon. They find that:—(1) In gonorrhœal diseases of the testicle the epididymis only is involved. (2) There is marked dilatation of all the tubes of the epididymis, the result of obstruction, which is due to the pressure caused by the infiltration of inflammatory exudation into the connective tissues surrounding the tubules. (3) Such obstruction may lead to degeneration of the seminiferous tubules, with resulting atrophy of the testicle. The author admits that most cases of epididymitis will recover with only medical treatment, but severe cases will not recover as rapidly or with as little apparent anatomical disorganisation as when operative procedure is employed. This is as follows:—An incision through the scrotum down to the tunica vaginalis is made at the junction of the swollen epididymis and testicle. The tunica vaginalis is opened in the same line, and the testicle delivered from it. Numerous punctures are made in the fibrous covering of the epididymis with a tenetome, these being deep enough to enter the infiltrated connective tissue. The tension under the thickened covering of the epididymis is markedly lessened. If pus escapes from any of the punctures, the opening is enlarged, and a small probe passed in the direction from which the pus flows. The cavity is syringed out. The testicle is restored into the tunica vaginalis, which is also thoroughly washed out. The wound is then closed with a cigarette drain of gauze at its lower angle. In every case operated on by the writer fluid resembling that found in gonorrhœal joints was found in the tunica vaginalis. In three out of the six cases pus was found in the epididymis. The globus minor was mostly affected. The relief following the operation is immediate, and seems to be just as great whether pus is found or not. The author concludes that operation is a rational procedure according to known pathology, and the danger to the patient is slight. The infiltration of the epididymis disappears more rapidly with this treatment than with any other. The danger of permanent injury to the organ is lessened. Patients are absolutely relieved from pain on recovery from the anæsthetic. The systemic symptoms are promptly relieved. S.

Some Principles of the Treatment of Fracture.—Bowser (*Brit. Med. Journ.*, October 27th, 1906) discusses the important modification which has been introduced during recent years into the treatment of fractures. This consists principally in the early employment of massage and movement, and in a less absolute adherence to the traditional methods of immobilisation. Prolonged immobilisation attends too exclusively to the solution of continuity of the bones, and neglects the associated injuries of the soft parts. As is seen in broken ribs, absolute immobility is not essential to bony repair. In certain cases immobilisation is necessary to prevent displacement only, and even in these cases experience shows that the length of time it is employed may be materially shortened. Wasting of the muscles, stiffness of the joints, weakness of the limb, and pain on attempting movement, are the common disabilities, which are, in reality, not due to the fracture, but to the treatment by immobilisation. Dissections have shown that intra-articular adhesions, fibrous ankylosis, erosions of cartilage, and various other injuries to the joint structures have resulted from the long-continued immobilisation of joints previously healthy. The bones, muscles, motor nerves and nerve centres themselves are differential parts of one organ of motion, and lesions of one induce lesions of the other. Therapeutic measures should take account of them all. Early massage and movement enables us to avoid many of the unfavourable results of immobilisation, and it is estimated by Bennett that the time that requires to elapse before a patient is permitted to resume his ordinary occupation is diminished by one-third. The massage employed differs from that of a professional masseur. It consists of a soft, smooth, uniform, and, above all, painless mobile pressure in the direction of the venous current. Ordinarily, massage is practised from the very beginning of the treatment, and repeated daily in séances of half-an-hour's duration. Massage prepares the way for movement. After massage, passive movements of the joints, which before had been impossible on account of the pain that they caused, become surprisingly easy. These movements, whether passive or active, are necessarily of slight extent, being limited by two imperative conditions—they must be painless, and they must not cause any new displacement of the bony fragments. The most striking results of massage are the relief of pain, the relaxation of muscular spasm, the removal of swelling, the maintenance of flexibility of joints and tone of the muscles. Kocher recommends the form of muscular exercise consisting of the voluntary contraction of muscles in certain fractures. S.

Cases of Pott's Disease, and of Coxalgia, Presenting Unique Features.—Rugh (*Med. Record*, October 13th, 1906) reports the following cases:—CASE 1.—Miss M. W., æt. 71, has good family and personal medical history. In May, 1903, she commenced to suffer from pains in the stomach. In June, 1903, she developed weakness in both legs, and difficulty in walking. She was treated in a hospital for three months, at the end of which time the patient was able to walk again. In November she was obliged to return to bed, and a small knuckle appeared in the dorsal region involving the 8th and 9th vertebræ. In April, 1904, spasmodic contractions of the legs and feet began, followed shortly afterwards by incontinence of the bowels and bladder. Patient improved somewhat by treatment in hospital, but eventually began to fail, and died in March, 1905. No abscesses had formed, but paralysis became complete before her death. The case is interesting on account of the development of primary tuberculosis of the spine in a woman of over 70, with no apparent causative history; also on account of the early and rapid onset of paralytic symptoms even before the appearance of the knuckle in the spine. CASE 2.—J. M., æt. 50, had no previous tuberculous history. In 1903 both testicles were removed for tubercular disease. In 1904 patient complained of pain in the stomach, as in Case 1. At this time a small prominence formed over the 7th, 8th, and 9th dorsal vertebræ. Patient improved with treatment. In May, 1905, patient complained of pain in the legs and lower part of the abdomen, and was found to have a tuberculous kidney. In May, 1906, the writer removed portion of the laminæ of the 7th dorsal vertebræ. The wound healed by first intention, and the patient left hospital with a spinal support. He was much improved and apparently on the way to complete recovery. CASE 3.—A man, æt. 38, is of interest as showing the extremely slow onset of Pott's disease. In spite of heavy work being constantly engaged in by the patient, without any form of mechanical support or treatment for his disease, seven years elapsed before he was forced to give up work for the first time. Since treatment has been begun the patient is progressing very favourably. CASE 4.—J. J. M., æt. 72. When eight years of age (1837) contracted hip disease. He was treated by George McClellan, at that time Professor

of Surgery to Jefferson College. Abscesses developed later, and were opened by Dr. McClellan. When he was 12 years old (1841) the abscesses healed and the hip was ankylosed. He grew to manhood, followed his trade, married, and reared a family. In 1901, when the patient was 72, without any known injury or cause, pain began in the hip and thigh. A few days before presenting himself at hospital, three of the old sinuses reopened. When seen by the writer, the sinuses were discharging purulent matter in every way similar to tuberculous pus. The character of the sinuses and pus, and the manner of onset, left no doubt in the author's mind that it was a re-lighting of an old process from which the patient had apparently recovered sixty years previously. S.

Indications for Surgical Intervention in Diseases of the Stomach.—J. Blake (*New York Medical Journal*) calls attention to the limits and uses of gastric surgery, and points out that gastric surgery is more hindered than helped by a mistaken idea of its possibilities. Operations may be divided into three main procedures: First, repair of wounds and perforations; second, improvement of drainage; and third, partial excision. The indications for the surgical treatment of any condition depend upon whether it will be benefited by one or more of these procedures, and whether the benefit is commensurate with the risk. In the first place the indications for operation are clear, in the second class the author asks for a more frequent surgical treatment of ulcer of the stomach, and gives a series of excellent results obtained by gastro-entersostomy in such cases. In the third class of cases, if we wait until we can say with certainty, "this patient has gastric carcinoma," in most cases it will be too late to operate. We must, then, determine on a set or group of symptoms which, when present, will indicate an operation, although they are not diagnostic of any one condition. Operation should never be refused, where there is a chance of benefit, particularly in those cases where the drainage of the stomach is interfered with. G.

On Access to the Knee Joint.—H. Russell (*Intercolonial Medical Journal*, August, 1906) describes a method of exposing the knee joint by means of a longitudinal incision carried from a point two inches above the patella across the middle of this bone to a point about two inches below it. When the soft parts are divided the knee is partly flexed and the patella sawn into two halves by a longitudinal saw-cut down into the joint, the divided halves are pulled to either side, the joint completely flexed, and in this way thoroughly exposed to the operator; when the joint has been dealt with the leg is straightened and a catgut sature passed above and below the divided halves of the patella to prevent the bone separating; the skin is then closed in the ordinary way. The advantages of this method are: Avoidance of need for wiring the patella; avoidance of even that temporary impairment of the strength of the patella, or any other of the joint structures; more perfect access to the lateral recesses of the joint, and supra-patellar pouch, than can be obtained by any other method.

A Fatal Case of Scopolamine Poisoning.—G. Ely reports (*New York Medical Journal*, October 20, 1906) the case of Mrs. T., aged 29, suffering from carcinoma of the larynx; heart, lungs and kidneys were normal, she was considered a suitable subject for the administration of scopolamine; accordingly, at 6.30 a.m., she was given hypodermically $\frac{1}{4}$ of a grain of morphine, and $\frac{1}{100}$ of a grain of scopolamine. Contrary to instructions, the patient rose from her bed and moved about for half an hour, and then lay down, falling at once asleep; soon after she became slightly cyanosed, and her breathing markedly stertorous, mouth dry, surface of the body pale and dry, the superficial reflexes were abolished; all attempts at rousing her failed, respirations became shallower, and two hours after the administration of the drug the patient died from respiratory failure. That death was due to the administration of the drug alone seems to be almost certain, as her organs had been examined by several different physicians and found to be normal.

The Surgical Treatment of Aneurism.—R. Lozano reports (*American Medical*, September, 1906) five cases of aneurism treated by the intra-saccular method of suture, as devised by Matas, of Orleans. From these cases the author draws the following conclusions: (1) That this method will cure aneurisms as radically as the method of extirpation. (2) This method of suture is exempt from the majority of post-operative complications, which usually follow the classical methods of treating aneurism, and for the control of hæmorrhage. (3) This method of suture can be applied to all aneurisms that are surgically accessible in any part of the body, whereas the method of extirpation is not practicable with safety in all regions of the body. (4) The method of intra-saccular suture is the most favourable for the preservation of the collateral circulation, as this is not disturbed in any way by suturing the orifices of the vessels inside the sac. (5) The method of intra-aneurismal suture is the only operative procedure which offers any prospects of radical cure in the treatment of abdominal aortic aneurisms. (6) The advantage intra-aneurismal suture has over the ligature is that it offers a stronger, more resisting barrier to the bloodstream above the line of obliteration, and is thus much less liable to secondary hæmorrhage than the ligature, which has invariably failed in every case of abdominal aneurism operated by ligation up to the present time. G.

The Making and Dressing of Wounds.—M. F. Porter says (*American Medical*, September, 1906) it is an easy matter to overdo the attempt to render the skin or an accidental wound aseptic. Buried sutures are advocated wherever possible, for buried sutures are less likely to be a source of infection than through and through sutures are. Sutures, re-dressings, and drains are necessary evils, hence all sutures should be discarded in favour of the bandage and adhesive plaster when these can be made to serve the same purpose, but when the use of sutures is imperative, then buried absorbable sutures should be preferred, buried non-absorbable temporary sutures should be our second choice; through and through sutures should be only used on compulsion, and buried permanent sutures discarded except in work on the hollow abdominal viscera. Our aim should be to do the first dressing so that it will be the only one needed, until healing is accomplished, and where this is impossible our efforts should be directed towards preventing the necessity for frequent dressing. When in doubt, do not drain, but if drainage is imperative, let it be adequate without being harmful, kept up while it is needed, and discarded as soon as it has fulfilled its mission. G.

Infection of Corneal Wounds by Saliva.—G. Hotta (*Klin. Monatsbl. f. Augenheilk*, September, 1905) experimented on rabbits, cats, and mice by inoculating saliva of persons of various ages and classes into their corneæ. Three kinds of wounds were made, viz., abrasions, pocket wounds in the corneal lamellæ, and perforating wounds. After twenty-four hours cover glass preparations from the wounds were made and cultures taken, the media being neutral agar, glycerine agar, Löffler's blood serum, and bouillon incubated at 35 deg. C. Ninety experiments were made, with the following results. The thirty perforating wounds gave negative results. One of the thirty abrasions was positive. All the pocket wounds were positive. These last cases developed iritis, hypopyon, and circumcorneal infection. Of the thirty pocket cases, pneumococci were detected 11 times, streptococci 17 times, staphylococci 9 times, and tetragenus 5 times No cultures were noticed in six of the cases. Hotta considers that muslin veils are quite effectual in preventing infection from the operator's mouth, although they are not an absolute preventative against spraying of the saliva. The possibility of infection seems so remote, although possible, that Hotta believes the veil to be unnecessary. M.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

NESCIENS.—(1) Yes. (2) Albuminuria, sometimes accompanied by a certain degree of cardiac dilatation, has been observed after hard exercise. Casts and blood have also been reported. (3) See "Munich. Med. Wochenschrift," 1906, Vol. III.

R. T.—From a table before us, which seems well grounded, we can supply the following figures:—171 cases with history of rheumatism, and 618 cases without such history. Of the former 34·5 per cent. showed cardiac lesion, of the latter 16·9 per cent.

MORS.—A prize for the discovery of an infallible test of death was offered as long ago as 1868 by the Marquis of Ourches, a French nobleman. The sum was £1,000, to be reduced to £500 if the test were only applicable by medical men.

KING STREET.—We believe the agency has long since died out. We cannot trace it later than 1887. But there are plenty of good modern ones.

W. H. T.—Sodium Salicylate is for the most part excreted in the urine salicyluric acid, a combination with amido-acetic acid.

SQUAMOUS.—We fancy that Scotch children will bear comparison with any as regards physique. Certainly they are not likely to be beaten by the French. See a recent address given by Professor Graucher before the Academy of Medicine, Paris. He found on examining 4,226 elementary school-children that some 15 per cent showed more or less definite signs of tuberculosis.

Dr. T. (Sheffield).—There is no satisfactory way of judging of the properties of preparations, unless they have been standardised. In the case of strophanthus—as in that of digitalis—physiological standardisation is the only trustworthy method. Several of the larger firms supply physiologically standardised preparations, and it is just as well to insist on having them.

M.D.LOND.—The election results were communicated to Convocation on October 9th. Dr. Gordon Little was elected.

RELATIVE POPULATIONS.

AN ACTUARY.—Your enquiry should have been addressed to the Registrar-General's Office. However, as we have the figures before us from the official source we give you them as follows:—London (not including the suburban area), 4,721,217; Glasgow, 835,625; Liverpool, 739,180; Manchester, 637,126; Birmingham, 548,022; Leeds, 463,495; Sheffield, 447,951; Dublin, 378,994; Belfast, 366,220; and Edinburgh, 341,036. If you wish to take Greater London into your calculations the latest returns give the population as 7,113,561.

MR. B. L. C.—We do not profess to unravel puzzles: the point is a nice one. Write to the office of the General Medical Council.

TU QUOQUE (Leeds).—On inquiry we find that the book is out of print. Perhaps a copy could be obtained through a second-hand bookseller.

ANTE-DATE.—We should advise our correspondent to consult a solicitor.

M.R.C.S.—A book, little read now, Hilton's "Rest and Pain," would probably give our correspondent the information he wants.

DR. PRINGLE.—We hope to have space for your communication in our next. Mr. Stewart Johnson's letter came to hand as we were "at press," too late for present issue.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 14th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m.: Discussion on Gonorrhœa. Short Papers will be read by Dr. L. Smith, Dr. E. Michels, and Dr. R. Andrews.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m.: Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Pardoe: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

THURSDAY, NOVEMBER 15th.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20 Hanover Square, W.).—5 p.m.: Demonstration: Prof. W. D. Miller: Some Observations and Experiments on the so-called Erosion of the Teeth.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11 Chandos Street, Cavendish Square, W.).—3 p.m.: Papers:—Dr. R. P. Smith: The International Congress on the Care of the Insane held in Milan last September. Dr. R. W. Branthwaite: Drunk and Disorderly. Dr. P. Stewart: Diagnostic Value of Examination of the Cerebro-spinal Fluid.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. F. H. Broadbent: The Diagnosis and Treatment of Duodenal Ulcer.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Mount Vernon Hospital, Hampstead).—5 p.m.: Demonstration: Dr. J. E. Squire: Cases of Chest Disease.

FRIDAY, NOVEMBER 16th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5 p.m. Cases will be shown by Dr. E. I. Spriggs; Dr. T. R. Whipham, Dr. F. Cautley, Dr. Carpenter, Dr. Hawthorne, Dr. J. F. Parkinson, and others. Paper:—Dr. J. Burnet (Edinburgh): Psoriasis in Childhood.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.:—Mr. R. Lake. Clinique. (Ear.)

Vacancies.

Gloucester County Asylums.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

Dorchester County Asylum.—Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Barnsley Hall Asylum, Bromsgrove, Worcestershire.—Senior Assistant Medical Officer and Deputy Medical Superintendent. Salary £200 per annum, with furnished quarters, board, washing, and attendance. Applications to the Medical Superintendent.

Aberystwyth Infirmary and Cardiganshire General Hospital.—House Surgeon. Salary £150 per annum, with board and residence. Applications to R. T. Edwards.

Saint George's Union, London.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing. Applications to the Clerk to the Guardians, St. George's (Hanover Square) Hall, Mount Street, London.

Palmer Memorial Hospital (for Accidents), Jarrow-on-Tyne.—House Surgeon. Salary £150 per annum, with board and residence. Applications to Andrew W. Young, Secretary.

Saint Andrew's Hospital for Mental Diseases, Northampton.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Appointments.

DIXON, R. G., M.B., Ch.B.Leeds, House Surgeon at the General Infirmary, Leeds.

FLINT, E. R., M.B., Ch.B.Vict., House Surgeon at the General Infirmary, Leeds.

GOULDEN, CHARLES, M.B., M.C., F.R.C.S., Senior House Surgeon at the Royal London Ophthalmic (Moorfields Eye) Hospital.

HUDSON, A. C., M.D., B.C., F.R.C.S., Second House Surgeon at the Royal London Ophthalmic (Moorfields Eye) Hospital.

LANDMAN, A. J., M.B., Ch.B.Leeds, House Physician at the General Infirmary, Leeds.

MACVEAN, H. J., M.B., Ch.B.Vict., House Surgeon at the Bradford Royal Infirmary.

SCARBOROUGH, O. L., M.R.C.S., L.R.C.P.Lond., Resident Obstetric Officer at the General Infirmary, Leeds.

THOMAS, JOSIAH TELFER, L.R.C.P.Lond., M.R.C.S., Surgeon to the Camborne (Cornwall) Public Dispensary.

TURNER, GEORGE GREY, M.B., M.S Durh., F.R.C.S.Eng., Honorary Assistant Surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne.

VEALE, R. A., M.B., B.S.Lond., Resident Ophthalmic Officer at the General Infirmary, Leeds.

Births.

COLBY.—On Nov. 9th, at Hill View, Woking, the wife of Francis E. A. Colby, M.B.Camb., F.R.C.S.Eng., of a son.

TOWNSEND.—On Nov. 11th, at 184 Hammersmith Road, Hammersmith, the wife of Meredith Milton Townsend, L.R.C.S., L.R.C.P. Edin., of a son.

Marriages.

COOPER—FOSTER.—On Nov. 10th, at St. James's Church, Hampton Hill, Middlesex, Philip Ward, fifth son of the late Horace Cooper, M.R.C.S., J.P., of Marlborough, to Katharine, youngest daughter of C. R. Foster, of "Armaside," Hampton Hill.

HAINES—STAGG.—On Nov. 10th, at St. Gabriel's, Willesden Green, Charles Frederick Haines, L.D.S., R.C.S Eng., of Worthing, younger son of the late Edward S. Haines, of Stourbridge, and Mrs. Haines, to Vivien Dorothy Cowley, youngest daughter of the late William Stagg, of Cumberland.

ROBERTS—BROWSE.—On Nov. 6th, at St. Luke's Church, Richmond, Edward Hugh Roberts, M.R.C.S., L.R.C.P.Lond., D.P.H.Cantab., of Battersea Park, London, to Violet, second daughter of the late George Henry Browse, of Paignton, Devon.

TIMMINS—SEARLE.—On Nov. 6th, at St. Mary-the-Less, Cambridge, John Lewes Timmins, M.A., M.D., eldest son of John Aaron James Timmins, M.D., late of Mount Hill, Carmarthen, to Ermengard Philippa, younger daughter of the Rev. William George Searle, M.A. (late Fellow of Queen's College, Cambridge), of 11 Scroope Terrace, Cambridge.

Deaths.

HICKS.—On Nov. 8th, at Guildford, Sophia, daughter of the late Robert Hicks, F.R.C.S.

NORTON.—On Nov. 11th, at 23 Grove Road, Brixton, Selby Norton, M.D., aged 70 years.

ROCH.—On Nov. 9th, at Woodbine Hill, Youghal, Ireland, Dep. Surg.-Genl. Sampson Roch, late 55th Regt. and Army Medical Staff, aged 77 years.

THE MEDICAL PRESS AND CIRCULAR.

VOL. CXXXIII. WEDNESDAY, NOVEMBER 21, 1906. No. 21

NOTES AND COMMENTS.

The Jungle chez nous.

EVER since the Chicago sensations shook the foundations of belief in preserved food, we have contended that it is the merest hypocrisy for Englishmen to cast stones at the Americans in the matters of the inspection of food supplies and the conditions under which food is prepared. In a book published last week under the sensational title of "The Soul Market," the authoress, Miss Olive Malvery, has a vigorous fling at several provision concerns in this country. We are not prepared to support or to deny her assertions as regards the particular ones attacked, but we may say in general terms that the "revelations" as to the conditions under which the hands work, the general want of ordinary cleanliness, the putrid state of meat used for preserving, and the decayed condition of fruit used for jam, are exactly what may be expected in a country that regards the production of food as a matter beneath its notice.

A few Details.

MISS MALVERY tells, for instance, of a London meat-packing factory in which tongues and pork, used for pressing and making brawn, were so putrid that they fell to pieces, the smell they emitted being shocking. In times of pressure, she says, the staff was replenished by relays of tramps from the gutter and riverside, whose bodily condition was offensive beyond description. As the entire staff of meat-inspectors of the Port of London, into which some half a million tons of meat are annually imported, is but eight, what can be expected? The facts related in "The Soul Market" call for a rigorous inquiry.

Coventry Dispute.

THERE is apparently a tough fight proceeding at Coventry between the practitioners of the neighbourhood and the Provident Dispensary. The latter possesses no less than 18,000 members, and is therefore in a strong position to make terms. The medical men object, naturally and rightly, to the Dispensary embracing in its membership well-to-do people who are capable of paying ordinary fees, whilst the Dispensary point to the Friendly Societies, which have similar terms for contract practice and number many affluent persons among their adherents. The last move of the Dispensary partisans is a mean one. Dr. Snell, the Medical Officer of Health, is acting as secretary to the local branch of the British Medical Association, and in that capacity is making things "go." Now an attempt is being made to get the City Council to prohibit his holding this purely honorary position, and thus to deprive the movement of much of its influence. We wish all success to the medical practitioners, and trust that the methods of the Dispensary partisans will not be allowed to prevail with the Council.

Vaccination Anomalies.

LAW and logic do not kiss each other in the Vaccination Act, 1898, and the situations that are continually arising in consequence are often grotesque in the extreme. Last week a complaint to the Home Secretary was made by Mr. Lupton, who owes his position in Parliament largely to his anti-vaccination prejudices, that a man mamed Walden had twice been refused an exemption certificate by the Greenwich magistrates, and is now being prosecuted for not having his child vaccinated. The Home Secretary replied that he had no authority in the matter, and that the statute places discretion as to exemption entirely in the magistrates' hands. That is true, and so we see the curious anomaly of a man being disallowed exemption by the magistrates, and prosecuted by the vaccination officer for non-compliance. It cannot be contended that these paradoxical situations bring much credit either upon the law or the practice of vaccination.

Working-Class support for Hospitals.

A JUST criticism with regard to hospital management is that it does not seek to ally itself with the class for which it caters, and consequently the working classes in London and many other places feel and show no interest in hospitals till they are taken ill. In some large provincial towns the active co-operation of the working classes is sought for by the governors and easily obtained, and such hospitals are seldom or never in debt. A striking illustration of the amount of interest taken by the workers of London in the hospitals was reported last week. At Acton, the governing body of the local hospital sent round eighty collecting boxes to large works in their district so that the employés could contribute their mites, undeterred by fear of ostentation. The mites, however, were not forthcoming, for when a collector went round, not one of the eighty contained a coin!

LEADING ARTICLES.

SOME ASPECTS OF MODERN EDUCATION.

MANY of our readers will probably agree with Mr. Birrell's views of education, as expressed at the meeting in the Town Hall, Leeds, on Saturday, November 4th. One important point, however, seems to have received little or no attention. In the terse definition of education—"Doctrina vim promovet insitam"—we have the great principle stated on which education is founded, and by which it should be influenced and regulated. We naturally ask, What is meant by "vim insitam"? What promotes or develops the inherent qualities—that is education? But it follows that before we decide how to educate we must study carefully and know well what are the inherent qualities we have to deal with. By way of comparison, from which much may be learnt, we see what is done in the training of dogs. To try and make a rat-catcher of a Sussex spaniel, or a sheep-dog of a Scotch terrier, would be regarded as rather silly, and we know that we look to the breed of a dog when we begin to train it. Mr. Birrell says that "it would tax more powerful intellects than his to determine where elementary education ended and secondary education began." Human beings, like dogs, differ greatly in their inherent qualities, and it is on the analysis of these qualities that education depends. It looks as if these—that is the "vim insitam"—are really directly due, in their variations, to the simple facts of how the senses of sight, hearing, smell, taste, and voice are developed. In human beings, as in dogs, we see strange variations in the state of the senses; but we have something more to consider when dealing with our own species, namely, the singular qualities that are purely, as far as we can tell, possessed by the brain independently, as it seems, of any of the senses. The power of memory, of calculation, of invention, may depend on some one sense, but we cannot satisfy ourselves that the superiority in some great quality of one man over others can be proved to be due to the unusual development in his case of one of the senses. How is it that one boy may be a good classic, and another a good mathematician? How the brains differ in these cases is strange, and we are disappointed if we try to train the two in exactly the same way. In this country we have left education to those who have been interested in the training, not of the senses, but of the mental powers or qualities of the young. Those who are engaged in the study of law, in the teaching of religion, or in such work as that in which Mr. Birrell excels, are not capable of dealing with the question of education when it is really one of a physiological and physical character. Indeed, none are capable of dealing with the points who have no knowledge of those sciences that are the special study of the medical profession, or of some branch of natural science. Law and theology are naturally more disposed to cultivate languages and literature and moral philosophy and religion than the common nature of human beings—the "vim insitam," the animal qualities we inherit, or are endowed with. "Education began the moment we were born, and ends with the grave. It did not therefore do to exaggerate the more scholastic side of it." We cannot but admire the mode in which Mr. Birrell is dealing with the question of education, and it would be well for those who are following the profession of medicine not to stand aside in a spirit of indifference when they can help so much in the support of Mr. Birrell, when he says "that nothing could ever rob him of the conviction that the education of our race was our gravest problem."

A STATE MEDICAL SERVICE FOR IRELAND.

As will be seen from the report which we publish in another column of the proceedings at the recent Special General Meeting of the Irish Medical Association, the latter body decided by an almost unanimous vote to approve of the principle of the conversion of the present Poor-law Medical Service into a State Service. We can most heartily congratulate the Association on their decision on this, one of the most critical matters which has come before them for some time past. It is no exaggeration to say that not alone was the future welfare of the Association bound up irrevocably with the decision, but also the future welfare of the entire Poor-law Medical Service of Ireland. In particular we desire to congratulate the President, Mr. McArdle, on his wise and statesmanlike change of attitude towards the scheme. As we have said, the opposition of the Association would have been a most serious matter, and it is almost equally necessary that no opposition should be offered by its President. Consequently, we are very pleased to learn that he gave the scheme a whole-hearted support. At its meeting on Friday, the Royal College of Physicians also approved the scheme, and we have little doubt that the Royal College of Surgeons will do likewise. Approvals of this kind are very necessary preliminaries, but, if they are to bear fruit, something more is necessary; and, if the Poor-law Service is to be really altered, medical men must take their coats off in earnest, and work steadily to compel the Government to give effect to the Report of the Commission. It is always difficult to obtain the necessary money for reforms, and the present case will be no exception. The scheme starts with the great advantage of being recommended unanimously by a Commission. In addition, it is known that it will benefit all those with whom it is concerned from the "ultimate peasant" to the members of the Service. Consequently, there is every hope of its accomplishment if it is only kept prominently before the public. In this connection, we regret to see that the general press are not giving the matter the amount

of publicity which its importance warrants. We trust that this is due to accident rather than to design, and that it will be speedily remedied.

NOTES ON CURRENT TOPICS.

"Normyl" Treatment for Alcoholism.

The "Normyl" treatment for alcoholism has several times been the subject of comment in the MEDICAL PRESS AND CIRCULAR, and we have also had the honour of being replied to by the Rev. Hugh Chapman, secretary of the Association for its employment. Our readers therefore scarcely require to be reminded that this "treatment" is a secret one run for the profit of a private individual with no medical qualification, who has induced certain philanthropically-disposed persons to lend their names to the association. Mr. Chapman neglects no opportunity of advertising the treatment, in spite of medical advice to the effect that all these drink "cures" come and go like stars in their courses and that there is nothing in them that is not known to every intelligent medical man. He has now carried the matter into a new phase, for the *Daily Mirror* is selecting five men and five women to undergo the treatment under its supervision, the results of course to be announced in its columns from time to time. Now, is the *Daily Mirror* in earnest? If so, it will appoint an entirely independent committee first to decide whether the victims are what are truly and properly called drunkards, for it is perfectly useless to accept mere *ex parte* statements, or the patients' own word. Then it will publish nothing about the "treatment" for two years or more after the process has terminated, and when it does do so it will make very careful examination as to relapse. Medical men know well that there are no liars like alcoholics, and that their friends will say anything to screen them.

Infant Mortality in Dublin.

THE Coroner of Dublin, Dr. Louis Byrne, has done a public service in once again drawing attention to the high rate of infant mortality in Dublin. It is difficult to obtain any accurate comparison between the rate in the city of Dublin and those in other large towns, since the rates are calculated on the Dublin Registration Area, a district including not only the suburbs but a considerable stretch of country. In the week ending the 3rd inst., however, of 155 deaths registered as occurring in the city, 29 were of children under one year of age, and 28 more of children under five. It would appear, therefore, that more than one fourth of all the deaths are of young children. When it is remembered that but few Dublin mothers are employed in industrial occupation, and consequently that there is but little artificial feeding of infants, it is obvious that the rate is excessive. The fact is that no serious attempt has ever been made to instruct mothers in Dublin in the proper care of their children, and in the proper methods of feeding, where natural feeding has to be abandoned. There is, further, no guarantee that pure milk can be obtained, and it is no uncommon thing to see milk, filthy in appearance and offensive in smell, exposed for sale. Overlaying is a cause of many deaths. Before dealing with this the housing problem must be settled, but, in the meantime, the poor could be taught to use cradles of some sort—old boxes are excellent—instead of taking their children into their own beds. The truth is, however, that in Dublin as in Belfast, the work of the public health authorities is in a scandalously backward state, and the whole system needs revolution.

"When Doctors Disagree."

The recurrent scandal of opposing "expert" medical evidence constitutes a standing reproach to a scientific profession. A thing cannot be and not be, although that is what one gathers from the evidence of five medical men in a compensation action brought against a Hanley colliery company last week. The plaintiff had been knocked off a trolley and sustained injuries which two of the medical men described as fracture of the sternum and of five ribs on the left side, complete dulness in the axillary region, dulness generally, and other signs of serious injury to the lung. The man spat blood for some considerable time after the accident. On the other side two medical men asserted that the lungs were healthy, but the judge clearly did not accept that view, as he allowed the plaintiff 12s. 2d. a week for six months, subject to revision at the end of that time. This case is emphatically one in which two or three experienced medical men could have arrived at an absolute agreement in consultation. Some day it may dawn upon the legislature that the administration of cases involving medical opinion would be placed on a surer, speedier and sounder economical basis were they to be referred to an independent medical board for examination and report. The present system lends itself to obvious abuses and miscarriages of justice, especially in the case of poor suitors, who cannot pay high fees for expert evidence.

A Case for Enquiry at Clacton.

THE week before last a retired medical man was heavily fined for damaging chairs belonging to the District Council, and sent to prison without the option of a fine for wilfully obstructing a cyclist. The extraordinary circumstances of the case suggest that it would be advisable an immediate enquiry should be made into the mental condition of the gentleman in question. His extreme eccentricity has long been in evidence, and, if we remember aright, has been actually commented upon in our own columns. Amongst other things, he has been before the magistrates on a previous occasion for firing a loaded revolver in the street on a dark night. In the present instance he mounted a heap of chairs and threw some of them over the cliff, and the second charge was due to his putting out

his foot and upsetting a cyclist who was passing on the road. We submit with confidence to the authorities that the facts as stated are more than sufficient on the face of them to warrant an immediate informal *de lunatico inquirendo*. The state of the British law as regards police-court and criminal insanity generally is lamentable and wholly unworthy of a scientific age. Lawyers, who make and administer the law, as a class obstinately refuse to recognise the irresponsibility of moral insanity, unless the accused be a drivelling idiot or a wild maniac. But we are glad to remember that the Home Secretary, who has the revision of sentences in his hands, is a common-sense citizen and not a lawyer.

Army Nurses and Dancing.

THE answer recently given by Mr. Haldane in reply to a question why dancing should be forbidden to nurses in the Army Nursing Service, does not perhaps reach the high level of sanity that one associates with the Secretary for War. Mr. Haldane admitted that he himself saw no reason why the nurses should be forbidden to go to dances, but that the experienced matrons and highly trained ladies on the Nursing Board had prevailed over him. Now the Nursing Board is an estimable institution, and no doubt these experienced matrons being long past the dancing age look upon that innocent pastime with the eye of the fox for the sour grapes. But if nurses are to remain human, and not to develope into a caste, it is eminently necessary that they should continue to be of the world as well as in it. It is a stupid piece of prejudice that forbids them dancing, and the sooner it is removed the better.

A Pure Milk Supply.

A pamphlet has just been issued by the Royal Institute of Public Health embodying the report of a committee which they appointed some time ago to enquire into the question of the purity of the milk supply. The committee was composed of medical officers of health, bacteriologists, and representatives of the milk trade. They recommend that the Dairies, Cowsheds, etc. Order of 1885 should be enlarged and strengthened. The order is not nearly so strict as most in operation in the Colonies. It was found that enforcement of existing orders varies in stringency in different parts of the country, and in a large majority of rural districts the orders are completely ignored. The committee urge that the enforcement of the orders should be compulsory upon the local sanitary authority, and in default the authority should be made amenable to the County Council. Perhaps when the legislature has finished fighting over the religious aspect of the educational problem, and has settled all the other questions of high politics likely to absorb its energies for the next few sessions of Parliament, it may be able to turn aside to the small details of the social problem, to devise laws which may tend to prevent the deterioration of the populace upon whose physical vigour the stability of the nation and the empire so largely depend. It has been stated over and over again by the highest authority that if existing sanitary legislation were uniformly carried out with intelligence and zeal throughout the kingdom the annual mortality might be speedily reduced by one-half. The mortality is only a measure of the injury to the physical development of the people by which it is accompanied; and in the matter of milk supply, for example, it is probable that for every infant dead a score survive as ricketty cripples owing to lack of a proper supply of the only food they are capable of digesting and assimilating.

Medical Motorists.

It would be useless to suppose that the proposed tax on automobiles is likely to be popular —that is to say, so far as the mere pleasure-hunting motor is concerned. Obviously it would be an unsound economic proceeding to tax industry by placing an impost upon automobile vehicles used for trade purposes. The question is where to draw the line, a difficulty that is always present in an attempt to establish differential taxation. At a conference of automobilists held in London last week a resolution was carried by a small majority to uphold the favourable treatment of medical men in regard to the taxes on motor vehicles. There is a good deal to be said on behalf of such a proposition, inasmuch as the medical profession forms an indispensable pillar in the social edifice. A vehicle of some kind is absolutely necessary to the general practitioner, especially in country districts, for the proper conduct of his practice. It is not so many years ago that the national voice was raised in condemnation of a proposed tax upon wheels, and it is not altogether easy to realise how there can be any exceptions to the general rule that such taxation curtails industry. In any case it is to be hoped that the short-sighted policy of taxing the locomotion of medical men will not be adopted by the Government.

The Learned Laity.

A LABOURER who came lately to a large London dispensary described himself to the doctor as suffering from "brain-fag," his diagnosis being doubtless gleaned from the symptoms given under that heading in some of the dailies, and an office-boy who came with an hypertrophied liver, gave the doctor the gratuitous information that he had "inflamed membranes," because his "sister, who went to the Physiology Class," said so, and she knew "all about your inside." It is doubtful whether the writing of many books by doctors in a style which might be understood by the intelligent laity, but which are likewise read by the empty-minded, is a very wise procedure, and still more harm is done by medical faddists who use such titles as "menticulture," "humaniculture," etc., and almost imply that disease when it comes is curable by home treatment. A melancholy instance of the right book in the wrong hands is that of "Andrew's Domestic Medicine," with the pages marked at the effects of poisons being found in the room of a young suicide.

The Health of Dublin

The focussing of public attention on the scandalous neglect of sanitary matters in Belfast has allowed the state of health in Dublin to pass almost without notice. Nevertheless, it is not to be forgotten that, high as is the death-rate in Belfast, it is much higher in Dublin. During the September quarter of the present year the respective rates for the two county boroughs were 18·8 and 24·1. Since September, however, the rate in both cities has gone up, and, according to the latest returns, Dublin shows not merely the highest death-rate in Ireland, but the highest in Europe. To find a parallel to Dublin in its mortality it is necessary to travel to India, where Bombay and Madras take the lead. Even Calcutta, where there has been much discussion lately as to the necessity for improved sanitation, shows a lower death-rate. The people of Dublin, however, do not seem in the least alarmed about the matter. A few voluntary societies, such as the Dublin Sanitary Association and the National Association for the Prevention of Tuberculosis, do their best to educate public opinion, but of united effort by the responsible authorities there is little. Dublin is riddled by tuberculosis, and is periodically attacked by typhoid. Typhus is seldom absent for any length of time; diarrhœal diseases more than decimate the infant population. The water supply is not above suspicion, and the milk supply is far from properly controlled. It is not clear, of course, how far a death-rate accurately represents morbidity, but in a city with such an extravagant death-rate the people have a right to expect more than ordinary precautions for the prevention of disease. Their responsibility in this matter has not yet been brought home to the proper authorities.

The Prevention of Lunacy.

The question of the possibility of the limitation of lunacy by legislation is at least as old as Plato, and in recent years it has been revived with a fresh interest. A paper contributed by Dr. Nolan, of Downpatrick, to the October number of the *Journal of Mental Science* is, unlike much writing on the subject, a sober and reasoned discussion. Recognising that State interference in other matters relating to public health has been more than justified, he asks why the function of the State in regard to mental health has up to the present been limited to the protection of the unfit. The question is difficult to answer beyond stating that most of the proposals put forward have been unpalatable in themselves, and have not been backed with sufficient authority to force them on an unwilling public. It remains to be seen whether Dr. Nolan's own suggestions will meet with a better fate. Some of them are undoubtedly sound, such as those for the establishment of a Ministry of Health and of a State Laboratory for Investigation of Mental Pathology. It is more than doubtful, on the other hand, whether early and consanguineous marriages, if otherwise healthy, have any effect in producing mental instability. Most of Dr. Nolan's suggestions, however, are thoroughly feasible, and the wider the audience reached by his paper the better.

PERSONAL.

Princess Louise, Duchess of Argyll, opened the new wing of the Central London Throat and Ear Hospital, Gray's Inn Road, on Monday last, when purses were presented in aid of the building fund.

Mr. Thomas J. Stafford, Medical Commissioner on the Local Government Board of Ireland, has received the Order of Companion of the Bath on the occasion of the recent Birthday Honours.

The Lord Lieutenant has appointed Mr. John Fagan, F.R.C.S.Irel., to be a member of the General Prisons Board for Ireland in room of Dr. Stewart Woodhouse, resigned.

Dame Marian Saunders, of Wimbledon Common, widow of the late Sir Edwin Saunders, for many years surgeon dentist to Queen Victoria, has left £1,000 to St. Thomas's Hospital, for the endowment of a bed in memory of her husband, and £100 each to the following institutions: The Westminster Home for Nurses, the Chelsea Hospital for Women, the Benevolent College, Epsom, and others.

The annual meeting and dinner of the Glasgow University Club for Manchester and District will be held at the Mosley Hotel, Manchester, on November 27th. Further particulars can be obtained from the secretary, Dr. D. Richmond, 176, Drake Street, Rochdale.

Sir T. Halliday Croom, M.D., will preside at the next annual dinner of the Edinburgh University Club of London, which takes place on Friday, November 23rd, at the Criterion Restaurant, Piccadilly Circus, at 7.30 o'clock.

A special meeting of the Medical Society of London will be held on Monday, December 3rd, at 9.15 p.m., when Dr. Henri Hartmann, Professor of the Medical Faculty of the University of Paris, will deliver an address entitled "The Surgical Forms of Ileo-cæcal Tuberculosis."

Dr. P. Watson Williams has been unanimously elected Physician in Charge of the new throat and nose department of the Bristol Royal Infirmary. Dr. Williams has been connected with the Institution for the last eighteen years.

The Council of King's College, London, have appointed Dr. Arthur Whitfield, F.R.C.P., Lond., to the Professorship of Dermatology.

We regret to record the death of Dr. Gustave Isidore Schorstein, of the London and Brompton Consumption Hospitals. Dr. Schorstein passed away on November 16th.

The Treasurer of the Royal Ear Hospital, Dean Street, Soho, has received from the Duchess of Somerset £160, the proceeds of a concert given by her Grace at 35, Grosvenor Square, on the 6th inst., in aid of the funds of the hospital

Dr. J. Lindsay Steven, Member of the General Medical Council, Physician to the Glasgow Royal Infirmary, has been appointed by the managers of the Western Infirmary, Glasgow, to succeed the late Dr. Finlayson as visiting physician.

A CLINICAL LECTURE
ON
THE MEDICINAL AND DIETETIC TREATMENT OF CATARRHS OF THE BLADDER AND PELVIS OF THE KIDNEY.

By G. EDELSSEN, M.D.,
Professor of Surgery at the University of Hamburg.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE communications regarding the treatment of catarrh of the bladder during the past ten years are almost exclusively concerned with the newer chemical remedies, whilst the older tried ones are rarely mentioned. At most uvæ ursi and copaiba balsam are considered; Posner points out oil of turpentine, and Quincke chlorate of potash. This one-sided consideration of the newly introduced remedies on the part of reporters—which, however, have in many cases proved their value—might lead physicians to the belief that where the modern remedies fail no more need be expected from internal treatment. But in such a tormenting disease as chronic vesical catarrh it is greatly to be lamented, and the reverse of agreeable to the attending physician, when hopes of internal treatment are not realised, and it is a misfortune to the patient when local treatment of the bladder is had recourse to, which the frequent accompanying pyelitis often makes it impossible to influence, before an attempt has been made to make trial of the internal remedies at our command to bring about the cure of the disease. No one will deny that all washings out of the bladder, whatever the drug employed may be, with its incalculable dangers, is most burdensome for young girls, and with men with strictures of the urethra almost impossible to carry out without an operation. Certainly there is an unavoidable necessity for local treatment of the diseased mucous surface of the bladder under certain conditions, but this method should only be looked upon as a last resort, to be made use of only when all attempts to act on the disease by internal remedies have failed.

The question, therefore, comes up whether the older remedies can be dispensed with since the introduction of the newer, whether in many cases they should not have the preference over these, and whether they must give place to them only in certain well-characterised cases. The newer remedies—urotropine, new urotropine, helmitol, hetraline, and the combined urotropine and fol. uvæ ursi uropural tablets—owe their activity, as is known, chiefly to the splitting off of formaldehyde within the body, which, excreted through the kidneys, acts as a urinary antiseptic, and in favourable cases, by killing the micro-organisms that set up and maintain the pyelocystitis, bring back the mucous surface of the bladder and renal pelvis to a normal condition. These remedies, therefore, are indicated wherever the disease of the urinary passages is caused by pathogenic micro-organisms, such as bacterium coli, typhoid bacilli, and staphylococci, or where the urine has been rendered ammoniacal by decomposition of the urine by other organisms. In these cases, therefore, they must be had recourse to at once, and before trying other remedies.

To-day it is almost an article of faith that every pyelocystitis is of bacterial origin, and the fact that we formerly obtained the best results with the older remedies does not contradict this. These remedies may also have had an antibacterial action, as is certainly true of the balsams and ætherial oils and the arbutine contained in the folia uvæ ursi, as well as of salicylic acid and salol. Chlorate of potash, indeed, has not this action, but it is possible that the excreted salt comes into contact in the urine with pus cells and gives off oxygen, and this in *statu nascendi*, or that one of the chlorine combinations poor in oxygen has a bactericide action.

With the older remedies, with the exception perhaps of salicylic acid and salol, the anticatarrhal vaso-constringing and secretion-checking action was the chief one; in the case of chlorate of potash the action was a directly healing one, and one that furthered the development of new epithelium. Whether, and in what degree, such an influence may be attributable to formaldehyde is at least doubtful. Certainly complete recovery is often brought about by urotropine and its substitutes; but the cases are not rare in which the ammoniacal fermentation is completely arrested, but in which the secretion of pus suffers no diminution on continuance of the treatment; where, indeed, even from the commencement no diminution of clouding or quantity of purulent sediment can be noticed. In gonorrhœal or tuberculous cystitis the powerlessness of the remedy cannot surprise, but one cannot from this negative result in non-gonorrhœal cases conclude that the disease is tuberculous. There may be other catarrhs of the bladder and renal pelvis that have been originally caused by micro-organisms that are capable of running an independent course of themselves, even after the originators of the affection have been rendered harmless, *and the longer the disease has lasted and the deeper the changes that have been set up by it, the less may be hoped that it will be cured by antiseptic treatment alone.* In these cases it is imperative to pass on to the use of the old, tried anticatarrhal remedies. But wherever also there is free secretion of pus, but no ammoniacal condition of the urine, and where col. bacilli or staphylococci are not present, there is every reason to bring into use the old vaso-contractile and secretion-checking remedies at once by which formerly such excellent effects were obtained. Where there is no pronounced bacteriuria nor excessive ammoniacal decomposition of the urine we shall do very well with the old remedies, and obtain by these means what is required to restore a normal epithelium and a normal condition of the urine, even better than with the modern ones.

Amongst these old remedies I place oil of turpentine, copaiba balsam, chlorate of potash, folia uvæ ursi, salicylic acid, and salol. In tuberculous pyelocystitis one will do best from the employment of creosote and guaiacol; in gonorrhœal cystitis with copaiba balsam, which is to be preferred even to gonosan. I have no experience of arhovine and santyl. The most powerful remedies in non-gonorrhœal cystitis are oil of turpentine and chlorate of potash. It is, indeed, less the doubt as to their efficacy that has made physicians turn from them to the newer remedies than the fear of the

injuries that may be caused by them. The use of oil of turpentine may occasionally be followed by strangury and even slight hæmaturia. But if the drug is stopped in time one need never fear any permanent injury. Even in acute catarrh of the bladder it does excellent service, and often brings about recovery in a few days, just in the same way as is often observed in gonorrhœal cystitis after treatment with copaiba balsam. Want of appetite is not a contra-indication against the use of the drug, for that is generally only a consequence of the main illness itself. It is often enough observed that in such cases the use of oil of turpentine or of copaiba balsam along with the favourable influence on the bladder improves the appetite also. It is only in grave gastric disorder that the remedy is contra-indicated.

A weighty objection to chlorate of potash is the poisonousness of large doses when given internally. This view widely spread has led to its avoidance in catarrh of the bladder, or to its being prescribed in doses so small that they can do no good. There is no reason for this excess of caution, however. Except in two cases recorded by Quincke, in which poisoning took place when the remedy was given for vesical catarrh in doses efficient for the purpose—*i.e.*, 0.5 to 0.75 grm. six to eight times daily, in adults—all the other known cases of poisoning by chlorate of potash were by the administration of a single large dose, unsuited to the age of the patient, or to smaller doses too rapidly pushed one after the other. Even when the small doses necessary in vesical catarrh are given, even when there are no symptoms of poisoning, and especially of methæmoglobinuria, a small number of the red blood corpuscles may be destroyed, but this slight loss of eventual erythrocytes must always be very quickly made good. For even when the drug has been given for months together I have never observed any loss of colour in the face or other sign of commencing anæmia; on the contrary, the patient's looks improved with the progressive improvement in the catarrh of the bladder. Independent, therefore, of some cases in which chlorate of potash is absolutely contra-indicated, there is no reason to avoid the use of chlorate of potash in the treatment of either acute or chronic catarrhal inflammation of the bladder.

But, indeed—this must be again emphasised—of a remedy the action of which depends on its being excreted through the kidneys chiefly in an unchanged condition, and on the degree to which it can be estimated in the urine, something can be promised only when it is given in a dose that allows the freest excretion possible in the urine. In my experience, in the case of adults, 0.75 six times a day answers well (15 ccm. of a solution of 15 grm. in 300 ccm. of water), equal to 4.5 grammes a day in six equal doses; but in unusually bad cases, when the patient is strong, the like dose may be given without any misgiving eight times a day—that is, 6 grammes per diem. That the dose must be modified in children, according to their age and constitution, goes without saying. The contra-indications against the use of chlorate of potash are only acute nephritis, general cyanosis the result of emphysema and cardiac insufficiency, or of congenital or other non-compensated acquired valvular disease of the heart, and also icterus.

As may be supposed, neither of the medicines will work equally well in every case. It may happen that where one has completely failed, the other has the best results. It cannot be determined beforehand in any particular case which of the two promises best. One must be given, and if it does not prove sufficiently useful the other must be put in its place. In very rooted cases a repeated change of the two remedies may be useful, and with a good function and tolerance of the digestive organs both may be given together for a time in the usual doses with perfect safety, and with a good result. In other cases a combination of chlorate of potash with fol. uvæ ursi has been very successful (chlorate of potash 15 grm, decoct. fol. uvæ ursi 3 : 300; one tablespoonful six to eight times a day). Where also there is no proper catarrh, but only an excessive irritability of the bladder (irritable bladder of the English), chlorate of potash may do excellent service.

Without being an opponent of all local treatment of vesical catarrh, I am of opinion that it should be used in those cases only in which internal treatment fails. It should not be undertaken without necessity, and physicians would be much less frequently placed in a position of being obliged to wash out the bladder if they more frequently made use of the old, tried remedies for cystitis. For washing out, the milder remedies will generally be sufficient, and especially the 3 per cent. solution of chlorate of potash recommended by Boegehold; silver nitrate will only be necessary in rare cases. Boric acid and resorcin, both in 2 to 3 per cent. solution, have also proved very useful. Washing out with permanganate of potash is not without danger, as the possibility is not quite excluded that the sediment caused may not in part adhere to the mucous surface of the bladder, and occasionally may give origin to a concrement.

It is not necessary to prescribe a special diet in order to bring about recovery in acute and chronic vesical catarrh. After a daily examination of the urine, I have never observed that the case got worse when any unpermitted articles of food were taken, or that the action of any remedy was in any way impeded. This applies as well to dark meats as to pickled or salted or smoked, and to fish; and as the favourable action of the æthereal oils or the products of their change within the system on the mucous surfaces is generally recognised, there seems to be no reason for prohibiting pepper, mustard, and other spices in moderate quantity, so long as the digestive organs and the kidneys are sound. I have even occasionally permitted asparagus; but perhaps it would be more proper to cross off the diet list for bladder sufferers a food that has no special nutrient value, and one that changes the character of the urine in such a striking manner. By allowing greater freedom in the choice of foods the appetite that frequently sinks under a monotonous diet is rapidly restored, and improved nutrition is of great importance in such a tedious and weakening disease.

The forbidding of the use of alcoholic drinks is well founded. Even slight excesses in this direction have resulted in a marked increase in the vesical catarrh. During the course of treatment of a case of cystitis or pyelocystitis, both acute and chronic, spirituous liquors are to be forbidden to the patient entirely. In chronic catarrh of the bladder, people who have been accustomed to wine, however, may have a little red or Moselle wine mixed with water allowed. Beer certainly does harm, owing to the hop it contains—and especially new beer—and which, according to the researches of Rintaro Mori, if taken in large quantities causes severe irritation of the bladder mucous membrane, even in healthy individuals, and is to be looked upon as the cause of the so-called beer-drinker's clap (Biertrippers).

As regards the allowance of water, the old maxim was fully justified that a free supply of water should be allowed, enough to provide for efficient dilution

of the urine and washing out of the bladder in the natural way. Whether plain water or milk, buttermilk, or diluted tea, or mineral water, is of no consequence, so long as the urine is acid; but when the urinary reaction is alkaline, all alkaline mineral waters are to be avoided, and only plain water or effervescing mineral water, such as Seltzer, Apollinaris, or Hanza Sauerbrunnen or Kaiser Friedrich, Quelle, Oberbrunnen or Gieshubl or Wernarzer Brunnen, should be allowed, and in cases of acute vesical catarrh, even when the urine is acid, are to be preferred to the Wildunger, Fachinger, Vichy, and Biliner waters. With the dilution of the urine, with its diminished irritating action on the mucous surfaces of the bladder and urethra, the frequent desire to micturate ceases, and by-and-bye the cutting pain felt after micturition. In spite of the increased quantity of urine, therefore, the intervals between the different acts of micturition become longer. But it must be borne in mind that the urine must not be so much diluted that the remedy passes through in an insufficiently concentrated form to produce its effects, and so is less active. The mineral waters that very justly have a name as useful in bladder cases, and especially those of the Wildunger Spring, should not be taken to such an extent that they interfere with the action of the medicinal remedies.

NOTE.—*A clinical lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor F. Widal, M.D., Physician to the Paris Hospitals, on "The Dechloridation Treatment in Cardiac and Renal Disease," specially reported for this journal.*

ORIGINAL PAPERS.

A PLEA FOR THE STUDY OF THE INTERMEDIO-LATERAL TRACT OF THE SPINAL CORD. (*a*)

BY ALEX. BRUCE, M.D., F.R.C.P.ED.,
Physician to the Edinburgh Royal Infirmary,
AND
J. H. HARVEY PIRIE, B.Sc., M.B., B.Ch.

IN a *resumé* of the development of our knowledge of the anatomy of the intermedio-lateral tract, Dr. Bruce recalled that it had been described by Lockhart Clarke in 1851 as extending from the lower cervical to the upper lumbar region of the cord. In position it lay in the grey matter intermediate between the anterior and posterior cornua of grey matter. It attracted little or no attention after Clarke's time until Waldeyer described its position in the cord of the gorilla. According to him it extended into both the cervical and lumbar regions, but Dr. Bruce's observations showed that in man the tract began in the middle of the eighth cervical segment, and extended down to the middle of the second lumbar segment. It was an important tract as regards the number of its cells, which differed in appearance from those of the grey matter of the cervical and lumbar enlargements. The cells were arranged in two groups, one behind the other; to the former the speaker provisionally gave the name "lateral," to the latter, which overlay the formatio reticularis, he applied the name "reticular." The next matter raised was the question as to whether the cells of the intermedio-lateral tract were the spinal centre for the efferent fibres of the sympathetic system. Gaskell had discovered that the sympathetic fibres were of two kinds—medullated and non-medullated—the former being the efferent fibres. Drs. Bruce and Pirie had counted the cells in the intermedio-lateral tract in serial sections of the cord, and showed their distribution graphically on a chart. On comparing this chart with a scheme of the sympathetic system, it was found that in those segments from which the largest numbers of efferent sympathetic fibres sprang there were the largest numbers of cells in the tract in question. The coincidence was so striking that it was difficult to avoid the conclusion that the tract and the sympathetic system were related, and that the former was the spinal origin of the efferent fibres of the latter. The examination of this region of the cord, therefore, in cases in which there was affection of the sympathetic system, might be expected to yield results of interest, and in illustration of this specimens were shown taken from a patient who had died from acute anterior poliomyelitis. There was absolute flaccid paralysis of the lower limbs with abolition of the reflexes and some implication of the bladder and rectum. Towards the end of his illness the patient suffered from pyrexia from cystitis, with profuse sweats. It was then observed that however copiously the perspiration flowed from the face, arms, and upper part of the body, the skin of the legs remained absolutely dry. Dr. Bruce had therefore hazarded the opinion that there would be found, in this case, lesion of the intermedio-lateral tract as well as of the anterior horns. The specimen shown confirmed this, for the same congested appearance, with degeneration of the cells, was seen in both sites. The question might be raised, why was this not more common in anterior poliomyelitis? The reason was, that the lesion was seldom extensive enough. In this case the inflammatory condition had involved not only the grey matter of the lumbar enlargement, but extended longitudinally into the dorsal region of the cord. He had also examined the intermedio-lateral tract in a case of another disease in which sympathetic symptoms were a prominent feature—namely, exophthalmic goitre. In it, as well as in other regions, he found hæmorrhages, which were probably terminal, and on which he laid no stress. But in the intermedio-lateral tract region there was also hyaline degeneration of the vessels, and degeneration of the nerve cells. Without entering upon the question as to whether these were the primary lesion or not, and whether the disease was or was not a condition of over-action of the thyroid, he suggested that the lesion found constituted the anatomical basis of the sympathetic symptoms of Graves' disease. Many other diseases in which symptoms due to involvement of the sympathetic occurred would suggest themselves, and he had brought forward his paper as a plea for the more thorough examination of the lateral region of the cord.

(*a*) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, November 7th, 1906.

Dinner of the Medical Graduates College and Polyclinic.

THE eighth annual dinner of the Medical Graduates' College and Polyclinic will be held at the Trocadero Restaurant, Piccadilly, on Wednesday, December 12th, at 7.15 for 7.30 p.m. Dinner tickets, 7s. 6d. exclusive of wine, may be obtained from the Medical Superintendent, 22, Chenies Street, Gower Street, London.

NOTES OF A CASE OF OVARIAN CYSTOMA IN WHICH THYROID TISSUE OCCURRED. (a)

By J. HUTCHINSON SWANTON, M.A., M.D., M.Ch., M.R.C.P., Lond.

Obstetric Physician to the Kensington General Hospital.

TUMOURS of this description are of such rare occurrence that it seemed opportune to exhibit this specimen, and read some notes of the case.

The patient, E. G., from whom I removed this tumour, was sent to me in January, 1903, complaining of attacks of nausea and vomiting, followed by a bearing-down sensation, which came on after standing every evening. She was 42 years of age, and stated her menstruation began when she was fifteen; the periods came on regularly every twenty-eight days, lasted five days, and used two diapers daily. Slight pain came on one hour before each period, which ceased when the discharge appeared. Married ten years, and had three children, the youngest aged 3½ and eldest 9 years. One miscarriage happened ten months previously, after four months' pregnancy, caused by taking an abortifacient.

Her labours were described as being good, but the perinæum ruptured during the first, and was sutured three days afterwards. Both kidneys were movable, the left lying in the iliac fossa. The cervix was lacerated on the left side, and the uterus was in an early stage of descent. Some thickening of the mesometrium on the left side was found near the upper border. The kidney on the left side was easily pushed back into the hypochrondrium, and after the application of a suitable pad and belt the symptoms complained of disappeared.

The patient was seen by me again on April 24th, 1906, and stated that on April 6th an attack of pricking pain came on during the night in the lower part of abdomen, which was relieved by fomentation. On getting up next day the pain returned and became paroxysmal. Menstruation appeared on April 16th, and lasted seven days. On examination the left iliac and lower hypogastric region were slightly prominent, and respiratory movements diminished. A definite swelling was found occupying these regions, which gave impaired resonance. The vesico-uterine pouch was occupied by a fluctuating swelling, which caused pain on manipulation. The uterus was not enlarged, but displaced to the right. The left fornix and adjacent part of the pouch of Douglas were occupied by a smooth resistant swelling, the size of a fœtal head at seven months, which could not be pushed up out of the pelvis. Several mucous polypi projected from the cervix.

I advised operation, and on May 8th of this year performed cœliotomy through an extramedian incision 6 cm. long to the left of the middle line. On opening the abdomen an irregularly lobulated mass was found wedged in the left side of the true pelvis. Anteriorly it was dark red, but behind was of a pearly colour, with isolated patches of dense structure irregularly distributed. There were no adhesions, and after enlarging the abdominal incision, the tumour was lifted out of the pelvis. The left ovary and mesovarium were taken up by the growth. A gauze packing was placed around the pedicle, and enclosed the tumour. One thin-walled cyst on the anterior surface ruptured during removal, but the contents were absorbed by gauze. The pedicle was ligatured, divided, and peritoneum sutured over the stump. The abdomen was closed by through-and-through sutures of silk orm gut; peritoneum was closed by continuous suture of catgut sterilised after Moschowitz's modification of Claudius's method. The sheath of the rectus was closed by interrupted silk sutures and skin united by catgut. The patient was then placed in the lithotomy position, when the ploypi were removed from cervix and uterus curetted. Two pints of saline solution, at temperature of 99°, were then injected high up into the rectum, before the effect of the anæsthetic passed off.

The temperature on one occasion within twenty-four hours after operation rose to 100° F.; otherwise convalescence was satisfactory, and patient returned home on the twentieth day. On July 25th the patient was examined, when there was only some thickening in the outer portion of left mesosalpinx.

The specimen was examined by Cuthbert Lockyer, who reported that—

In general appearance the tumour is tri-lobed, the lobes consisting of three large cysts, the largest measuring 3 inches in both its diameters; the next in size measures 2½ inches in both its diameters; whilst the third measures 2½ by 2¼ inches. The largest cyst has extremely thin walls, and is therefore quite translucent. By transmitted light yellow tissue is seen to exist in patches on the inner surface of the wall. The fluid from this cyst is of a greenish-yellow colour, and of limpid consistency. The other two cysts have thicker walls, the one intermediate in size is filled with thickish fluid, chocolate in colour, and laden with cholesterin crystals. Adherent to the inner wall of this cyst are irregular flakes of old blood-clot. The third cyst contains a fluid which is deep orange in colour and in which large flakes of lymph float about; on its inner wall are seen patches of bright yellow tissue, and in the substance of its wall the remains of a corpus luteum can be traced. The outer surface of all the cysts is perfectly smooth, showing no signs of adhesion. A few delicate capillaries form a network over the wall of the cysts. At the confluence of these three cysts there exists a solid mass of tissue, which on section presents a multilocular cystic appearance, the loculi being filled with solid colloid material. In addition, projecting from this solid mass there is a thin-walled cyst, circular in shape, with a diameter of 1 inch; the fluid contents of this small cyst are of a deep orange colour, and yellow flakes are seen on its inner wall. Externally, this solid mass presents a few very thin-walled cystic portions, which have been broken during removal. The fluid from the three large cysts becomes solid on boiling only after the addition of acetic acid. The fluid from the small cyst only partially coagulated when treated in the same manner. The pedicle of the tumour has been cut short, so that no mesosalpinx or ovarian ligament are to be seen.

Sections of each cyst-wall and also of the colloid central part of the tumour have been made.

The tissue has a thyroid structure consisting of loculi lined by low-lying cubical epithelium, and containing colloid material in which lie ghost-cells and spaces occupied originally by fat crystals.

The microscopical section shows a smooth outer capsule undergoing hyaline degeneration; inside the ovarian stroma is somewhat broken up with clear spaces between as if œdematous. Numerous groups of deeply stained nuclei are seen irregularly arranged, some of the cysts being more surrounded than others. Then comes a reticulated structure, and beyond this several cysts with low cubical epithelium. The central portion is stained wth eosin, and in some cysts is separated from the wall. In the central portion may be seen empty spaces, some oval, while others are irregular.

The case is more interesting from a pathological rather than clinical standpoint. Nine specimens of this variety of tumour have been described. In 1899 Gotschalk (1) was consulted by a woman, æt. 88, suffering from ascites and marked cachexia. On operating, a solid tumour of one ovary was removed. The patient was discharged.

Numerous small cysts were found in the peripheral part of the ovary lined with cubical epithelium and filled with colloid material. Several hæmorrhagic infarcts were seen between these cysts. It was called Folliculoma malignum, and there is some doubt whether this case ought to be included.

In 1903, R. Meyer (2) removed an ovarian cystoma, associated with a solid tumour of thyroid tissue, from

(a) Paper read before the British Gynæcological Society, November 8th, 1906.

a patient, æt. 55, who had ten children. The same year Adolf Glockner (3) showed a specimen of similar nature removed from a patient, æt. 57. The symptoms were caused by pressure; there was no ascites, and patient left the clinic twenty days after operation. In 1904 Kretschmar (4) described another case, occurring in a patient æt. 48, which affected the left ovary. Polano (5) described two cases, one of malignant nature, where the patient was well two years after operation. In this specimen the growth was characterised by large reticulated spaces presenting a honeycombed appearance, and showed normal thyroid gland, colloid bronchocele and malignant growth.

In 1905 Ulesko Strogonowa (6) showed a specimen before one of the Russian societies.

Eversman (7) described a specimen from Fritsch's clinic.

Last year Hamilton Bell (8) showed two specimens before the Obstetrical Society of London, and during the discussion Targett and Williamson mentioned some specimens they had seen.

The genesis of these growths presents an interesting topic for observation and speculation, and may be classified into physical, metastatic, and embryonal. That the appearance is due to pressure of the surrounding structures or of the contents is founded on the alteration which the thyroid undergoes in Graves' disease, as Edmunds has shown, where the colloid material disappears and cells formerly cubical become columnar, and also when the parenchyma becomes hypertrophied, the cells of the acini become flattened out. This may be an explanation where the acini are numerous, but in many of the sections nothing of the kind is found. The suggestion has been made that these are ordinary cystic adenomata undergoing some peculiar form of colloid degeneration. It is known that the thyroid gland contains thyriodin, which is an iodine combination. Bauman and Ostwald have applied a chemical test to these growths, and have found that 16.215 grams of the growth yield .000225 gram of iodine. This reaction has not been found in any other ovarian tumours.

Another explanation is that these growths are metastatic, having come either from a normal thyroid or one infected with malignant growth.

Some of the cases mentioned have had enlargement of the thyroid, but not all, and in the case I have described there was no enlargement during the period of observation. Normal thyroid gland may grow into blood vessels and give rise to osseous metastasis, as stated by Oderfeld and Steinhaus (9) but there is no evidence to show that this occurs in soft tissues. This opinion is held by Kretschmar, in the paper alluded to previously, although formerly he considered the growth an endothelioma. The most probable explanation is that these growths are embryomata, and more particularly teratomata.

The teaching of Wilms (10) is that a teratoma must consist of the three germinal layers, but subsequent observers, as Nauwerk (11) and Glockner (12), do not consider this essential, as either one layer or some differentiated cells of any layer may be evolved at the expense of the remainder. According to the embryologist Bonnet (13), ovarian embryomata arise from wandering blastomeres which escape from the fecundated vitellus during the process of cleavage, and find their way into the urogenital area. At the onset of puberty these become an elementary structure planed like the normal embryo and consisting of three layers. The normal ovary probably contains an internal secretion, and it is not unreasonable to suppose that in the course of development certain ovular toxines may be produced which act on the cells of the germinal layers in an analogous manner to that of hæmolysins on blood cells. (14)

Some evidence may be advanced that a change of such a kind does take place. Saxer of Leipzic, in 1902, made a *post-mortem* examination of a woman, æt. 46, who died from hypostatic pulmonary hyperæmia, and discovered a well-developed single tooth in the right ovary, which was otherwise normal. This tooth was enclosed by a wall of dense ovarian stroma 1 mm. thick, containing numerous lymphatic spaces. This specimen may be seen in the museum at Leipzic. (15)

The presence and persistence of this product of one of the germinal layers may be explained on the hypothesis previously stated.

The persistence of thyroid tissue may be partly attributed to the greater liability of women to perversions of the thyroid gland. Sir Thomas Watson has shown that of 360 cases of thyroid disease, 330 were women. Murray collected a series of 370 cases of myxœdema, and of these 322 were women. Run and Prudden (16) found that of 150 cases 113 were women.

The age incidence of thyroid disease is noteworthy, as it is s own that between 35 and 45 years, but especially between 40 and 45 years, women are most liable. It will appear from this that the decline of the reproductive function is synchronous with pathological changes in the thyroid in a large proportion of cases. When a teratoma of thyroid tissue exists in the ovary at the time of diminishing activity of the thyroid gland, a compensatory hyperplasia may take place, which subsequently develops into either an innocent or malignant growth.

I would therefore submit that the balance of evidence in this case is in favour of this growth being a teratoma.

MEDICAL TREATMENT OF UTERINE HÆMORRHAGE. (a)

By S. JERVOIS AARONS, M.D., C.M.ED., M.R.C.P.LOND.,

Pathologist to the Hospital for Women, Soho Square.

IT is with some diffidence that I venture to speak on the subject of the Medical Treatment of Uterine Hæmorrhage. The question is so wide that I fear that the time at my disposal would be far too short to enter into the matter at the length which the subject demands. I will, instead, read the notes of the various forms of medical treatment which I have used in those cases of bleeding from the uterus which necessitated medical attention. At the outset I wish it to be distinctly understood that I do not suggest for one moment that the medical treatment of uterine hæmorrhage is to be used to the exclusion of surgical treatment. So far from this being the case, I hope to show later that in several instances medical treatment has been used to improve a condition with a view to operative treatment later on. I do wish, however, to emphasise the fact that there are numerous conditions which yield to medical treatment, if they be but given a chance—cases which are too hastily advised to undergo operative treatment, when, with suitable medical treatment, they can be put right. I need hardly mention that it is useless to attempt the treatment of hæmorrhage, and I think this applies equally whether the treatment be medical or surgical, until the actual cause of the bleeding has been ascertained. It is essential that the diagnosis, as far as possible, should be based upon pathological research, as well as upon clinical grounds; the proper treatment can then be decided upon.

I have in these notes excluded all those cases which were treated surgically, except in a few instances which require mention on account of treatment received before operation was resorted to, or in one or two cases in which medical treatment was adopted when the condition was not relieved by operative treatment, and have related only those which, after a careful diagnosis, I considered suitable for medical treatment; and I may mention that these form the greater number of the cases which have come under my care, and it is this fact which induced me to lay before you the different remedies I have used. I am not suggesting that the means I have employed are original, with the exception of one, which, so far as I know, has never been applied to the treatment of hæmorrhage from the uterus, though it has been used in treating hæmorrhage from the lungs. I refer to the use of gelatin. The cases in which I have used it are only three in number, and, though successful in these cases, I realise that they are not sufficient in number on which to base any conclusions.

In order to save your time, and to avoid the tedium of reading through a list of cases, I have placed in your hands a tabulated list, showing the number, the initials, age, condition, cause, in so far as this could be ascertained, treatment employed, and result. In several of the cases many different remedies were tried, but I have only appended those which were successful in checking the hæmorrhage. For instance, in Case 3, ergot, hydrastin compound, calcium, and finally curettage were all tried. Even after curettage there was profuse menorrhagia during the two subsequent periods. I then tried gelatin, which was successful in reducing the periods. The scrapings from this case showed no signs of malignancy. In Case 24, several remedies were tried before the successful one was found—viz., neutral cotarnine phthalate. In Case 26, gelatin was again used with success, after curettage had failed. Case 67 had been curetted before the patient came under my care. Here cotarnine phthalate, which had been uniformly successful, failed utterly, as it did also in Case 73. Hydrastin compound was successful in both.

Case 41 is interesting in that I believe it to be due to hæmophilia, but there is nothing in the family history to support this diagnosis. There was no pelvic lesion that I could discover, but the patient had had a very severe hæmorrhage after the extraction of a tooth. She once cut herself with a piece of glass—only a slight cut—yet the bleeding was very difficult to control, and she states that she bleeds on the slightest provocation. Her periods have always been profuse; she has had two children; and after each birth she flooded. She was tried with ergot, hydrastin, adrenalin, and finally with calcium This last was successful in reducing the period from ten days to six, with a corresponding reduction in the quantity.

A word as to the drugs used. Ergot I used either as the liquid extract or ergotin hypodermically. The following formula, as suggested by Sir Alexander R. Simpson (1) is the one which I have always employed. I have had it put up in sterilised glass capsules, hypodermates, by Rogers:—

℞ Ergotin	...	...	...	ij. dr.
Aquæ	...	...	...	vj. dr.
Chloral hydratis	...	...	...	dr. ss.

Twelve minims of this equals three grains of ergotin. I always used it in those cases in which I deemed it necessary to obtain uterine contractions, such as subinvolution, in post-partum or post-abortum cases. In the same class of case I have used the hydrastin compound, a combination recommended by Macnaughton Jones (2), containing hydrastin, ergotin, cannabin tannate, and cotarnin hydrochloride (stypticin). This was employed either in the palatinoid form of Oppenheimer, or tabloid of Burroughs and Wellcome.

Cotarnine hydrochloride (stypticin) I have not used alone to any great extent. It has no advantage over the hydrastin compound, but it has the disadvantage of producing headache and giddiness. This sometimes happens with the hydrastin compound when continued for any length of time, and I am inclined to think it is due to the cotarnine hydrochloride contained in it.

Ernutin, which is said to contain only the active principle of ergot, I have used in one or two cases,

(a) Paper read before the British Gynæcological Society, November 8th, 1906.

but as it is not recorded in the present series, I do no more than mention it.

Of calcium I cannot speak too highly. The researches of Sir A. E. Wright (3) on the coagulability of the blood have given us a remedy for uterine hæmorrhage which, in suitable cases, cannot be overestimated. If it does not actually check the hæmorrhage in all cases—and I do not pretend that it does—it at least improves the quality of the blood, and, should an operation become necessary, it will be found that the condition of the blood, and consequently of the patient, is very much improved. Case 30 bore this out in a striking manner. The patient had a large fibroid, with profuse menorrhagia. She was given calcium, which slightly checked the hæmorrhage, but it was remarked at the operation (hysterectomy), which took place three weeks after the first administration of calcium, in what good condition her blood was. Probably most of us have noticed that in these cases the blood has a very watery appearance. It has also been remarked that in operations for gallstones (4) the administration of calcium chloride prior to the operation, especially in those patients who are jaundiced, by increasing the coagulability of the blood, lessens the tendency to bleeding. I regret very much that the coagulability of the blood in the above cases was not determined. I feel convinced that in many of these cases the coagulable point would be found to be much below normal, and particularly in fibroid disease. I hope later to investigate the coagulability of the blood in similar cases.

In a paper by Wright (5) on chilblains, he showed that the coagulability of the blood in this condition was always below normal, and he proved, by the administration of calcium, by bringing the coagulable point up to normal, that the chilblains could be cured. I mention this because, in two cases of menorrhagia, 33 and 57, both were sufferers from chilblains, a fact I was not aware of until both wrote and told me that during the winter they were taking the medicine they had no chilblains, and asked if it were due to the medicine, and, in view of Sir A. E. Wright's statement, I have no doubt that it was. I have used both the chloride and lactate, and find one as good as the other. The lactate is the more pleasant, or, perhaps I should say, the less disagreeable, of the two. I have prescribed them in the following manner:—

℞
Calcium lactatis ... ... xxx. gr.
Aq. Chloroform ad ... ... oz. j.
Sig: To be taken three times daily an hour before food.

℞
Calcium chloridi ... ... xxx. gr
Ext. glycyrrhiz. liq. ... ... xxx. m
Aq. Dest. ad ... ... oz. ss.
Sig: To be taken with an equal part of water three times daily.

The medicine should be taken throughout the period, and I think that it is advisable to take it at least a week before the period is expected.

Neutral cotarnine phthalate is, as far as I know, not very well known in this country, though it has been employed extensively in Germany. Katz (6) states that styptol is the neutral phthalic acid salt of cotarnine. Cotarnine is a base which was prepared some time ago by Wohler by oxidising the opium alkaloid narcotine with manganese dioxide and sulphuric acid according to the formula:

$$C_{22}H_{23}NO_7 + H_2O + O = C_{10}H_{10}O_5 + C_{12}H_{15}NO_4$$
Narcotine Opianic Acid Cotarnine

The hæmostatic action of cotarnine is well known, it having been tested in the above-mentioned drug, stypticin, which is the hydrochloride of cotarnine. The trials rested at first entirely upon the external application of phthalic acid and of acid phthalic acid, but it was found that this acid salt had an irritating action, so that the neutral phthalic acid cotarnine was adopted.

This neutral phthalic acid cotarnine, called styptol, is a yellow, crystalline powder, readily soluble in water, and contains about the same amount of basic cotarnine as does the hydrochloride—viz., 73 per cent. It is given in doses of ¾ grain three or four times daily. I have, however, in some cases given 2 grains four times daily As will be seen on reference to the table, I have used this drug fairly largely, and with very gratifying results, and in only two instances, referred to above, did it fail to check the bleeding. How it acts I am not prepared to say, but inasmuch as it has, in addition to its powers as a styptic, sedative qualities, I think I may safely say that it does not produce uterine contractions. I think it is probable that it acts on the vaso-motor system. This assumption is supported by the following experiments conducted by Möhr (7). A rabbit near the end of gravidity, weight 2,700 grammes, pulse 210, respiration 184 per minute (anæsthetised by urethane). Laparotomy was performed under all precautions, while the animal was in a salt bath. One uterine cornu with a knuckle of intestine were exposed. After half an hour a hypodermic injection of 50 cgms. of styptol was given. Half an hour later weak peristaltic movements appeared in several intestinal loops; the uterus and its appendages, however, remained perfectly quiet, although its ability to contract was proved by direct faradic stimulation of the muscle.

The next experiment was made upon a rooster. It is well known that when roosters are fed upon ergotised corn for some little time, the combs and wattles, which are extremely vascular, become gangrenous. Möhr gave a young healthy rooster 5 cgms. of styptol daily for four weeks, then 7½ cgms. daily for two weeks, and finally 10 cgms. daily for one week. The tips of the comb retained their normal colour throughout, and the bird remained in perfect health.

In two cases of carcinoma, 48 and 64, one inoperable, and one in which operation was refused, besides checking the bleeding, it had quite a marked analgesic effect. This was also noticed in Case 93—membranous dysmenorrhœa. I have not tried the remedy locally, but I have no doubt that, used as a dusting powder in cases of inoperable carcinoma, where there are large, raw, sloughing surfaces, it would promptly check the bleeding and also relieve pain. Indeed, Abel (8), who has used it externally in this manner, says that the powder acts directly upon the exposed open vessels, and considers that this local action is due to the phthalic acid contained in the neutral cotarnine phthalate. In hæmorrhage of the climacteric it is especially useful, and in not one case of this kind in my series did it fail. I have seen no unpleasant after effects such as giddiness, headache, or gastric disturbances.

One case, 90, miscarried, but I do not think that this was due to the action of the drug. The bleeding had ceased some little time, and she had discontinued the drug. The other case of pregnancy continued to term. I have at present another case five months pregnant, who had slight hæmorrhage, who is taking the drug, and at present she is perfectly well. I think in neutral cotarnine phthalate we have a very valuable aid in checking uterine hæmorrhage.

The use of gelatin as a means of treating aortic and other deep-seated aneurysm by causing coagulation of the blood was first suggested by Lancereaux (9). I had long thought it desirable, after reading his paper, to try it in uterine bleeding, but considered the risks of subcutaneous injection too great to warrant my using it in this manner, but a paper by H. M. Tickell (10) on "The Gelatin Treatment of Hæmoptysis," in which he suggested using gelatin by the rectum, quoting successful cases, induced me to try it, for I thought that if it could check bleeding from the lungs when administered in this manner, it should also be able to check bleeding from the uterus.

In the following three cases it did check the hæmorrhage. In Case 3 the patient's period usually lasted 12 days, even after curettage. With gelatin it was reduced to 5 days and a corresponding reduction in quantity.

The gelatin is prepared in the following manner:—50 grammes (about 1¾ ozs.) of the best French gelatin

are dissolved in 1¼ litres (2 pints 3¾ ozs.) of boiling water. This is boiled very gently for one hour, when the volume is reduced by evaporation to 1 litre. The solution is then cooled down to the body temperature, and a quarter of a litre (nearly 9 ozs.) is slowly passed into the rectum by means of an ordinary irrigator. It is preferable to have the solution made up by a reliable chemist, and if the bottles (each bottle containing sufficient for one dose) are sealed with paraffin, there is no likelihood of the solution becoming infected. If this is done the following course should be adopted:—Place the bottle containing the sterilised gelatin in water, and bring the heat up to 100 deg. F. Place the funnel and tubing of irrigator in very hot water for a few minutes. Pass the tube into the rectum, and slowly pour the gelatin into the funnel. The injection is given three times daily, and is to be retained. In the cases in which I used it, the injections were given on the third day of the period, and usually two days' medication was sufficient to stop the excessive discharge. In fact, by the end of the second day, the discharge had practically ceased. On only one occasion was the injection returned, and I think this was due to nervousness. It was the first one given, and the patient thought that it would act on the bowels. I may say that it has no such action.

The advantages of rectal administration over subcutaneous injection are many. First and foremost there is no danger of infection. This is a very real danger when given subcutaneously, and one that is extremely difficult to eliminate, gelatin being a splendid culture medium. There is no raising of the body temperature, and there is no necrosis, and, according to Tickell, it has the same effect in checking the hæmorrhage when injected into the rectum as when given subcutaneously.

The question may be asked, why, if you give it per rectum, sterilise it? Well, as I have just pointed out, gelatin is such a good soil for the growth of micro-organisms that, in my opinion, it would be taking a great risk of introducing, perhaps, very virulent organisms (anthrax in particular) into the economy. The sterilisation takes place during the preparation, so that there is no extra trouble involved, and if the precaution of sealing the bottles hermetically is adopted, I think there is no danger whatever. I have not been able to use this remedy in many cases. It is a little difficult to carry out. It must be done by a skilled nurse, particular care having to be observed, especially in regard to the temperature, as the gelatin solidifies very quickly, and I find that, in private at all events, patients have a decided objection to rectal medication. I hope, however, to make a further and more extensive trial. I am fully aware that the cases reported are very few, but the uniform success I had with all three tried, I think, warrant my mentioning it.

Of local applications to the interior of the uterus I have no experience except after curettage, and I think that if it is found necessary to apply any medicament to the interior of the uterus in order to stop bleeding, it is infinitely better to curette, and then apply the styptic, and have the scrapings examined by the pathologist.

A number of these cases were seen among Dr. Dauber's out-patients at the Hospital for Women, Soho Square, and I gladly take this opportunity of offering him my warmest thanks for his permission to make use of the material.

I am fully aware, sir, of the many imperfections in this short communication, and feel that I have but touched upon the fringe of the subject. Still, I hope that I have been able to show that there are many conditions of uterine hæmorrhage which are amenable to medical treatment.

THE OUT-PATIENTS' ROOM.

CHILDREN'S HOSPITAL, PADDINGTON GREEN.

Hysterical Torticollis.

By Arthur Edmunds, M.S., F.R.C.S.

Among the out-patients was a girl, æt. 11, who came complaining of her head being on one side and of a large lump in the neck. The history was that she had always been a weakly child; she had suffered from one definite attack of rheumatic fever. The condition of the neck had gradually come on in the past few months. The child was very thin and poorly nourished. Her chest was very flat from before backwards, with a depressed sternum; there was also slight mitral regurgitation. The head was in a position of extreme deformity, inclined to the right, and twisted on itself into the ordinary position of right-sided contraction of the sterno-mastoid; the bodies of the cervical vertebræ could be distinguished at the side of the neck, where they felt at first like a large bony tumour. On entering into conversation with the girl, it was obvious that, although only a little girl, she was hysterical. Her laugh was a giggle, and her movements were erratic, almost choreiform. Mr. Edmunds said that there was here a definite rheumatic history as well as obvious hysteria. The patient was placed on a couch on her back, her attention distracted by talking to her, and an attempt made to correct the deformity. This could not be done quite at once, but the surgeon felt that peculiar quivering of the cervical muscles which showed that the deformity was due to muscles abnormally contracted, but not sclerosed or permanently shortened. With a little patience, he succeeded in getting the head absolutely straight; the swelling produced by the bodies of the cervical vertebræ then disappeared. Unfortunately, when the child was allowed to stand up again the deformity returned. It was obvious, Mr. Edmunds pointed out, that he had to deal with a case of slight rheumatic torticollis in which the hysteria enormously exaggerated the original manifestations. He was inclined to think that this was an example of the very general principle that a functional disorder rarely if ever arises *de novo*, but that the functional symptoms were an enormous exaggeration of the symptoms of a true organic disease. The two might not be present together, for it was possible for the original disorder to have passed away and the functional symptoms to persist. He frequently had children brought to him with a story of injury to the arm, usually quite a trivial one, which had resulted in complete loss of power. The child holds the arm to its side, refuses to allow the parents to handle it, and makes no attempt to use it for any purpose. The first task of the surgeon was, he considered, to eliminate an actual injury such as separation of an epiphysis or fracture of a bone in the neighbourhood of the joint.

This done, the case could usually be cured immediately. When firmly and unhesitatingly grasped, the arm is easily moved, and by distracting the child's attention, persuading it to extend the arm to reach some toy or sweet, the surgeon can obtain complete mobility of the joint. The child's attention is now directed to the limb, and the fact that he can move it driven home. The result of this treatment is usually permanent. Immediately after injury the arm has been painful, and the child has received the mental impression that it would always hurt to move the limb; this impression is removed by demonstrating the contrary. In the case under consideration, the rheumatism, Mr. Edmunds remarked, had practically ceased, but it was thought advisable to give the child a short course of salicylates. He had endeavoured on several occasions, he said, to create the impression in the girl that she could hold her head straight, but in vain; the deformity always recurred as soon as she left the consulting room. Accordingly he gave her an anæsthetic, and put the head up in a position of well-marked overcorrection, fixing it *in situ* by means of a plaster of Paris bandage. This was left on for a fortnight, at the end of which time it was found that the child had lost all tendency to the original deformity—in fact, there was a slight inclination to curvature of the neck in the opposite direction. This tendency had now disappeared, and the child's neck was at present straight; she still, Mr. Edmunds said, required a little discipline occasionally to prevent her relapsing into her old habits, but her condition remains extremely satisfactory. A general tonic treatment had been instituted at the same time with great benefit to her general health. These functional manifestations in children, Mr. Edmunds thought, were far from uncommon; a patient came under his care recently in which the spine was so curved and the muscles so contracted that the case was diagnosed as one of cervical caries with an abscess; a little manipulation, however, enabled the surgeon to ascertain that the disorder was purely functional, and that it was possible to put the head perfectly straight immediately. The correction, too, was permanent. This deformity had followed a trivial punishment at school, and had been increasing in severity for five weeks. These two cases, Mr. Edmunds thought, formed an interesting pair demonstrating the extreme deformities one can find in children, the causation of which is practically entirely functional.
